## ELOCUTION.

**E**LOCUTION is a term which, according to the strictness of etymological definition, might be applied to signify every thing that is included in the faculty and utterance of thought, by the means of language, whether oral or written; and some writers, even in modern times, have applied it, with more attention apparently to derivation than to authorized precision and necessary contradistinction, to written composition as well as to actual speech. At the same time, two other terms, oratory and eloquence, (which etymological refinement might undoubtedly reduce to the same original signification,) have admittance and current usage in our language, and are occasionally used as synonyms of elocution in our looser conversation. But every copious subject, when it comes to be treated in a didactic way, requires more terms of settled distinction than the simplicity of rigid etymology can be expected to furnish; and "many terms which, in the laxity of general conversation, are indifferently and indistinctly used, in the precision of scientific discussion must be carefully separated and placed in contradistinction: the very admission of synonyms being perfectly inconsistent with the progress and comprehension of scientific truth."

These three terms, therefore, in the very outset of the present subject, should be clearly and distinctly defined, and the boundaries of signification assignable to each, as terms of contradistinction, be precisely marked. This has accordingly been done by a popular lecturer of the present day. "Eloquence," says he, "may be defined, 'the art of expressing our thoughts and feelings with precision, force, and elegance; and of heightening the impressions of reason by the colourings of imagination.'" It is applicable, therefore, to the whole faculty of verbal discourse, whether oral or written. It addresses itself by the pen, to the eye, as well as by the living organs to the ear. Thus we speak (with ad-

mitted accuracy) of an eloquent book, as freely as of an eloquent oration; of the eloquent Buffon (alluding to his celebrated work upon natural history); and of the eloquent writings, as well as the eloquent speeches of Edmund Burke. The Apoptrophe to the queen of France, is as genuine a piece of eloquence as if it had been spoken in the house of commons.

Oratory, on the contrary, is precise and limited in its application: and, in this respect, indeed, even popular usage is pretty generally correct. It may be defined, "oral eloquence; or the art of communicating, by the immediate action of the vocal and expressive organs, to popular, or to select assemblies, the dictates of our reason, or our will, and the workings of our passions, our feelings, and our imaginations." Oratory, therefore, includes the idea of eloquence: for no man can be an orator who hath not an affluence of thought and language. But eloquence does not necessarily include the idea of oratory; since a man may be rich in all the stores of language and of thought, without possessing the advantages of a graceful and impressive delivery. It is, therefore, the name of a more complex idea; and includes, besides the general notion of eloquence, the practical part of elocution: which being our immediate object, must be spoken of more at large. "Elocution may be regarded either as a science, or as an act. In the former case it may be defined, 'the science by which the rules for the just delivery of eloquence are taught;'" in the latter, "the happy combination and coincidence of vocal, enunciative, and gestulative expression, by which oratorical excitement is super-added to the eloquence of thought and language." In other words: "Elocution is the art, or the act of so delivering our own thoughts and sentiments, or the thoughts and sentiments of others, as not only to convey to those around us (with precision, force, and harmony) the full purport

## ELOCUTION.

purport and meaning of the words and sentences in which those thoughts are clothed; but, also, to excite and impress upon their minds, the feelings, the imaginations, and the passions, by which those thoughts are dictated, or with which they should naturally be accompanied."

"Elocution, therefore, in its more ample and liberal signification, is not confined to the mere exercise of the organs of speech. It embraces the whole theory and practice of the exterior demonstration of the inward workings of the mind." In short, "eloquence may be considered as the soul, or animating principle of discourse; and is dependent on intellectual energy and intellectual attainments. Elocution is the embodying form, or representative power; dependent on exterior accomplishment, and cultivation of the organs. Oratory is the complicated and vital existence resulting from the perfect harmony and combination of the two."

The object, then, of the science of elocution is the improvement of oral language, as contradistinguished from mere graphic composition; and the cultivation of every external grace and accomplishment with which the delivery of language should be accompanied, whether in reading, in recitation, or in spontaneous utterance: an object, to the attainment of which the ancients devoted a very considerable portion of attention; and for the due comprehension of which, it appears to be necessary to go somewhat deeper in our researches into the physical and moral powers of man, than has been suspected by the generality of modern professors; and instead of calling in question, as some recent cavillers have done, whether elocution is even to be regarded as an art, to establish its doctrines on the settled principles of science, and demonstrate the essential elements of that science as a branch of natural philosophy. To the want of this due consideration of the subject, and to the incongruous maxims relative to it, are perhaps to be attributed not only the frequency of every species of disgusting impediment in modern speech, but the lame and impotent state of public speaking among us, when compared in its effects with the splendid and impressive oratory of ancient times. "In those parts of oratory, indeed, which relate to the arrangements of thought, and the energies of expressive language, there is no deficiency of existing models; and, certainly, no paucity whatever of pedantic rules and treatises. Cicero and Demosthenes still continue to speak to the eye, in all the eloquence of graphic words; and Quintilian and Blair (like two conspicuous luminaries, in the ancient and modern hemispheres of oratorical criticism) illumine the tracks of written language, and may help to inform us how orations should be composed. In this part of oratory, the present and the preceding generation have, accordingly, something to boast. But for the theory and practice of those impressive exterior demonstrations with which the delivery of such orations should be accompanied, to what systems, or to what models can the English student appeal? In short, eloquence has been cultivated among us with considerable diligence; but elocution has been so much neglected, that the very nature of the science seems to be entirely forgotten; and the few fragments of antiquity that have descended to us upon the subject, are evidently misunderstood by those who have pretended to comment upon them; and many of our most learned critics have either ingenuously acknowledged, or unwarily betrayed, their total inability to comprehend some of those very distinctions most indispensable to the expression and harmony of oratorical delivery: such, for example, as the musical accents of speech, or inflections of the voice in the harmonic scale; the proportions of respondent sounds

and cadences, and the essential contradistinctions of percussion, accent, and quantity."

Such is the language of the lecturer already quoted; who, to rescue the elements of elocution from this state of neglect and chaos, and to facilitate the general attainment of an accomplishment so generally desirable, proceeds, in his "Introductory Discourse," thus cursorily to state the extent and nature of the subject.

"Elocution," says he, "is, 1. Partly a science, founded on ascertainable principles, and susceptible of palpable demonstrations; 2. Partly an art, attainable by imitative application and observance; and subject to such laws as result from comparison of general principles with practical experience; and, 3. Partly an object of taste and sentiment, dependent on acuteness of perception, and delicacy and refinement of feeling.

1. "As a science its foundations are to be sought, 1st. In physiology; that is to say, in the anatomical structure of the elocutionary organs, and the laws of physical necessity, by which their actions and reactions are directed and circumscribed: some knowledge of which seems to be indispensably requisite to the complete development and exertion of their respective powers; to the supply of accidental and occasional deficiencies; and to the correction of those erroneous and defective modes of utterance, which, originating in negligent or vicious imitation, have ripened into habitual impediments. 2d. In music, the essential laws and accidents of which, with only one conspicuous exception;" the progress of the tune, in one instance, being by slides or accidental inflections, "lifting the voice up and down in the musical scale;" and in the other, by ascertainable intervals and perceptible gradations; "are as applicable to elocution as to song: all fluent and harmonious speech (even that of the most easy and familiar conversation) as necessarily and as absolutely falling into the rythmical division of musical bars, and into the two generic measures of common and of triple time, as the warblings of the most scientific singer on the stage; while several of the impediments which most seriously obstruct and deform the elocution of injudicious speakers, may be proved to originate in no other cause than the violation of these musical principles, and the consequent resistance of those physical necessities which limit the facilities of organic action, and with which the elementary principles of harmonic proportion so admirably and so mysteriously conform. 3d. In philology, also, elocution hath a basis, inasmuch as to the philology of the structure and composition of language, and to the acute researches of the etymologist, many of those disputed questions of pronunciation, quantity, and percussive accent, which have hitherto been surrendered to the arbitrary and fluctuating decisions of fashion, ought, in reality, to be referred."

To which might have been added that the time of speech itself, is, or ought to be, a result of philological perception: the quantities, emphases, and inflections of syllables, in all perfect speech, being dictated by the sense and import of such syllables; either inherent in their original structure and individual signification, or derivable from sentiment and association.

2. As an art, the laws of elocution are partly grammatical, as arising out of the structure and arrangement of sentences, and the consequent degrees of connection and relationship between the different words and members and portions of the discourse to be pronounced; partly harmonic, as connected with the practical regulation of the variations and proportions of harmonic sound, with which such discourse should be accompanied; and partly mechanical, or experimental,

## ELOCUTION.

mental, as relating to the motions and positions of the respective organs, by which the varieties of vocal and enunciative expression are produced.

3. As a matter of taste, elocution embraces the consideration of such peculiar habits of study, deportment, and association, as are favourable to acuteness and delicacy of susceptibility, both in the intellectual and the organic system, and give them their peculiar bias and direction. In this point of view, all the finer arts, and all the more intellectual accomplishments constitute essential parts of the studies of the finished elocutionist. He should have an *eye* for the glowing tints and flowing lines of picture, the proportions of architecture and the symmetries of statuary; an *ear* for the ravishing delights of music; a *perception* of the vital graces of look and attitude and motion, far beyond all that the dancing school and the opera house can teach; and a *soul* tremblingly alive to all the enthusiasm of poetry, and all the poignancy of sentiment and pathos.

In vindication of the claim of this science to such an ample field of illustration and accomplishment, an appeal may be made from modern maxims to the example of classical antiquity, to the facts that stand upon record, and the relics of ancient criticism that yet remain: for although much in the outset of the inquiry appeared to the lecturer in the light of original discovery, further investigation, we are informed, "convinced him, that many of those doctrines, which he imagined to be new, are only "restitutions of decayed intelligence;" and what has, in reality, been added to the treasures that well-directed labours might have redeemed from the overwhelmed ruins of classical criticism, is probably confined to the physiological parts of the subject, and the connection attempted to be traced between the primary laws of physical action and re-action, and the elements of musical proportion."

These, however, constitute a very essential portion of the science of elocution; and the student of that science must begin, in the first instance, by investigating the structure and offices of those organs upon which the functions of speech depend, which will be found to consist of two distinct classes, the separate actions and attributes of which, it is highly important that the professor at least should accurately comprehend, lest by mistaking the source of the defects to be removed, he should necessarily fail in the application of the remedy. These are, 1, the vocal organs, or those portions of the organic system employed by the human (or other animated) being in the production and variation of expressive sounds; and, 2, the enunciative organs, which, in the complication and perfection of their structure, are peculiar to man, and are employed in superadding to the sounds of voice, certain other specific impulses, constituting thereby the elements and syllables out of which are composed the whole mechanism of human language.

When, however, these two classes of organs are said to be distinct, that word is not to be understood in so absolute a sense, as to preclude the supposition of some of them discharging the two-fold office of modifying the tone and superadding the specific quality of literal element. The nostrils, for example, which constitute a very essential part of the complicated organization that gives character to individual voices, are the chief implement employed in forming the elementary sounds of *n*, *ng*, &c. while the teeth, and some other parts of the mouth, principally employed in the formation of the characteristic elements, have, also, a material operation in modifying the tone of the voice. The practical distinction is, however, sufficiently evinced, by the separate manifestation of their effects: the tones and inflexions of voice being exhibited in the most exquisite perfection by

several species of singing birds, who are destitute of the organization requisite for speech, and speech itself being capable of proceeding, in the human subject, in forcible whispers, that is to say, by the action of the enunciative organs on a mere stream of breath, without accompaniment of any tone, or sound of voice. Of this, however, more hereafter. See VOICE, ENUNCIATION, ORGANS OF SPEECH, &c.

From the structure of the organs, the physiological enquirer is next conducted to a consideration of the laws of physical necessity, under which the functions of these respective organs are performed; and the mode of operation by which volition accommodates itself to the restrictions inevitably imposed: an investigation which involves several topics of considerable curiosity. From the simple principle of pendulation (the primary and indispensable law of all reiterated action) are explained many of the essential phenomena of enunciative and vocal expression, as the trill of the R; the impracticability of reiterating identical elements, or pronouncing, in immediate succession, certain elements closely approximating in organic formation, without intervening pauses; the facilities of certain combinations of element, the difficulty of others, and, consequently, the physical causes of euphony and cacophony; (see EUPHONY, &c.) and, above all, the nature and causes of those radical differences in the qualities of successive syllables so well understood (in practice, and essence at least, if not in cause,) by the grammarians of Greece, and designated by them under the terms *thesis* and *arsis*, but the total inapprehension of which has been the cause of so much confusion in the theories and embarrassment in the practical instructions of modern professors. The leading dogmas of this system are so self-evident, their application to organic as well as mechanic motion, and to the actions of the organs of speech in particular, so demonstrable, and the coincidence of these actions with the phenomena of a certain alternate energy and remission in the process of verbal utterance so apparent, that it is only astonishing how the principle itself should have remained so long obscured. But there is still room enough in the world of scientific discovery for other Columbuses to crack the heavy end of other eggs. But our business is an abstract, not a declamation. Thus then, it is contended, that action is of two kinds, continuous, or proceeding for a certain space of time, in a certain direction, from one original impulse, as the flight of a dart by the impulse of the bow, or of a ball from the explosion of a cannon, &c.; or reiterated and capable of unlimited continuity, from successive impulse, as in the pendulum of a clock, the motion of the legs in walking, &c. But speech is not a continuous action proceeding for a certain space in a certain direction from one original impulse, like the flight of a dart, &c. but a series of reiterated actions like those of the pendulum, or of walking, &c. though much more complicated and diversified by variety of phenomena, and, for that end, by necessary modification of impulse. Still, however, speech is action, reiterated action, resulting from reiterated impulse, and consequently subject to the indispensable law of reiteration, namely, re-action, or alternation; for as the pendulum when it has made its full swing in one direction must re-act in the opposite direction, before the primary action can be repeated; and as when one of the lower extremities has been advanced at full stride before the body it must either be drawn back again towards its former position, or, by a more complicated pendulation, the body must advance upon the limb, and thus restore the original poise to give the other extremity an opportunity of similar action, before the leg first advanced can advance again; so when the tongue, lip, or uvula have acted in any given direction for the formation of

## ELOCUTION.

any given element, it must re-act silently or expressively either upon the primary, or in some new direction, before the same element can be repeated, or any other element, requiring a similar line of action can be formed. And so, also, when the primary organ of cadential or syllabic impulse (the cartilage that surrounds the larynx) has been once contracted for the impulsion of the more energetic note, a re-action of that organ, either silent or accompanied by another note of less energy, must take place before the contractile energy can be renewed. Hence are derivable all the phenomena that belong to, or are to be described under the denominations of *cadence, measure, rhythmus, metrical feet*, and other distinctions arising out of those radical and essential differences in the qualities of syllables, sometimes described by the terms *accented and unaccented*, and sometimes by the very same writers, in the very same page, denied the distinction of accentuation; and sometimes, also, confounded with the quantities, and by the denominations, of *long and short*, but with which most certainly, neither accent nor quantity have any thing whatever to do. (See ACCENT, MEASURE, RHYTHMUS, PROSODY, METRICAL FEET, QUANTITY, &c. See, also, POISE, THESIS, and ARSIS, PULSATION, and REMISSION, &c.) Hence, also, will be found derivable (not from caprice, or taste, or arbitrary invention, but from physical principles) the distribution of all vocal melodies (and thence by imitation of all other melodies) into the proportions and cadences of common and of triple time; (see TIME,) and hence some light perhaps may be thrown upon that curious and hitherto unfathomable question, the cause of the exclusive satisfaction received by the human ear from sounds that follow each other in those definite and simple proportions.

Having laid these foundations of theory on the solid basis of experiment, the elocutionary physiologist may proceed to practice, and the crown and pinnacle of his labours consist in the exposition of the nature and causes of the various impediments and imperfections of speech; and in the application of the proper remedies applicable to those defects, whether originating in organic deficiencies, or malconformations; or adopted from imitation, confirmed by the inveteracy of erroneous habit. (See IMPEDIMENT.) The practical part of elocution also necessarily includes all that relates to the education and management of the organs of speech; the improvement of the expressive powers of voice and enunciation; the laws of inflection, proportion and harmony; and the graces and accomplishments with which the delivery of speech (whether original or imitative) should naturally be accompanied; and by which its effects upon the heart, the judgment and the imagination may be heightened and confirmed. See PHYSIOGNOMICAL EXPRESSION, GESTICULATION, &c.

Such is the general outline of the science of elocution, according to the only professor of modern times, by whom the subject has ever been treated in a scientific point of view, and from the notes of whose public lectures this abstract is principally furnished; a science which, however neglected, deserves (for its practical application at once to the noblest purposes of public exertion, and the most familiar gratifications of private life,) a considerable portion of the attention of those who are entrusted with the education of youth. For if oratorical excellence be an object only to the few, yet that those few should have the means of cultivating those parts of such excellence which appear to be within reach of systematic tuition, is certainly highly desirable; and (not to dwell upon the consideration that it is not always practicable to foresee, during the season of early tuition, who shall, or who shall not, be among the number of that few to whom such accom-

plishment might be of primary importance) "some degree, at least, of elocutionary accomplishment is certainly desirable by all. There are few, indeed, to whom it would not be advantageous (at least in point of mental gratification) to be able to read, with emphasis and harmony, the fine passages of our poets, or the instructive and elegant compositions of our historians, moralists, and amusive writers:— There is, perhaps, scarcely any individual who has not, occasionally, experienced the advantage of delivering what he had to say with correctness, ease, and impressiveness; or (lacking this accomplishment) who has not felt the disadvantages resulting from such defect. Even in the social intercourses of private life, how great are the benefits of this attainment! How does it multiply the sources of innocent pleasure! What a zest does it impart to the highest, though most familiar, of our intellectual gratifications!"

"Fortunately for mankind," continues Mr. Thelwall, "this accomplishment, so universally, to be desired, needs never to be desired in vain. With those exceptions only, which result from deafness, or from mental imbecility, I shall, I think, demonstrate, that (by no greater sacrifice of time and effort than is usually devoted to less important sciences and much more frivolous accomplishments) correct and impressive elocution is attainable by all." He admits, however, "that hitherto, at least, the instances of such attainment have been exceedingly rare; that few are the Englishmen who converse with fluency and impressive grace; and fewer still who can read with tolerable harmony and propriety. Even in our churches, the sublimest passages lose their impressiveness from the imperfect manner in which they are delivered; and those very preachers who are most accomplished in every other particular, too frequently obscure, by the wretchedness of their elocution, the eloquent discourses they compose.

"But the causes of this it is not difficult to discover. We trace them, at once, in the almost universal neglect of this important branch of education. Even of the professed teachers, in this department, where is the individual who has properly explored the extent, or the principles of the science, or who has even suspected that science had any thing to do with the subject? It has almost been questioned whether elocution were even an art? Excellence has been regarded as the mere mysterious gift of nature or of fortune—as the original and unsolicited dispensation of a partial providence; which no education could secure, and which study and application were scarcely necessary to improve. With respect to the constituents of that excellence, mere taste and presentment have been regarded as the only arbiters; the very laws of inflection and proportion have been denied all foundation and existence in the utterance of modern speech; and pronunciation, tone, and melody, and even the constituent requisite of percussive accent, (upon which the individuality, the character and the force of spoken words essentially depend,) have been abandoned to the lawless rule of fashion and caprice." Introductory Discourse on the Nature and Objects of Elocutionary Science.

Elocution has by many been considered as contradistinguishable into three several kinds, reading, recitation, and spontaneous speech; and some professors have marked these distinctions so absolutely, as to prescribe different styles of utterance, both in vocal and enunciative expression, to the reader and the reciter, from those which they regard as belonging to the unpremeditative speaker. Mr. Cockin, in particular, in an ingenious dissertation (published without his name, 1775) on "The Art of Delivering written Language," has maintained this hypothesis; and has discussed the subject of these supposed differences under the respective

## ELOCUTION.

ize heads of accent, emphasis, modulation, expression, (of voice as well as gesture,) and pauses; for the latter four of which, see hereafter under their respective titles. This work, we are informed in the dedication, was altogether approved by Mr. Garrick, who assured the author "that the doctrine laid down in that essay agreed exactly with his own sentiments." The popular axiom, however, "read exactly as you would speak," (supposing it addressed to a good speaker,) seems, in its principle, to be a rule much more rational than any thing that even the ingenuity of Mr. Cocker, though applauded by Mr. Garrick, has been able to adduce. It is objectionable, indeed, on account of its impracticability; pointing out a degree of perfection that was never yet attained, nor ever will be, till perfection in other arts and accomplishments shall be attained also. But the principle is not, therefore, the less valuable; the models of perfection must not be discarded from our minds, because art could never yet completely realize them: and although there are impediments, perhaps insurmountable, in the way of giving either to reading or recitation all the ease, the grace, and the vitality of spontaneous speech, yet, in principle, they should assuredly be the same; for reading and recitation are only two different modes of imitating that nature, which spontaneous speaking exhibits in her original reality; and the imitation ought to be so much the more perfect and exact, as, in this instance, the artist has the exclusive advantage of operating not only on the model, but with the very materials which nature herself employs in her creations. Mr. C., however, contends, "that reading does not receive any of its beauties from the principles of imitation, being no copy, but only another kind of speech." That, generally speaking, it is so, cannot be denied: but it is so far from unquestionable that it ought to be so, that this may be perhaps assigned as the genuine reason why the *reading* even of those very persons produces only sleep, whose unpremeditated *speaking*, is the delight of all ears; and why lectures never interest the auditors, like spontaneous harangues.

There are, however, certain particulars of essential distinction in the practical facilities; and even capabilities of excellence, in reading, recitation, and original speech, which the student of elocution ought to understand, as thereby each may perhaps be brought somewhat nearer to perfection than can be expected without the due consideration of these circumstances. Thus, for example, spontaneous speech, springing immediately from the inspiration of feeling, with all the freshness and glow of original conception, is capable of a degree of warmth, ease, and flowing energy, which can belong only to first impressions and unpremeditated language. From this very circumstance, however, it is incapable of all the smoothness, proportion, and harmony, which a minute attention to euphony, construction, rhythmus, and quantity, may enable the reader and reciter to accomplish. The reader, on the contrary, who finds the language ready polished to his hands, and sees it spread out before him, has leisure for full attention to all the minutiae of rhythmical cadence; and if his ear be good, his perceptions acute, and his notions of the principles of elocutionary harmony correct, he may certainly attain a degree of perfection of utterance, in what relates to mere proportion and melody, which none but the reader must expect. But then, on the other hand, the reader (especially he who reads at sight; and if he has previously studied, he becomes, in a certain degree, a *reciter*), pronounces what he reads, not with the feelings of an originator, or imparter, but with the feelings of a recipient; his mind is passive while his organs only are active: hence, inevitably, a certain degree of coldness and unnatural restraint.

The reciter partakes of the advantages and disadvantages of both; and he has both advantages and disadvantages peculiar to himself. If what he should repeat be completely in his memory, he makes it, to a certain degree, his own, and may approximate to the ease of the spontaneous speaker, and the smooth melody of the accomplished reader, though he can never completely attain the unsophisticated warmth and vitality of the former, or the complete rhythmus and nicely measured pauses of the latter. At the same time, by repeated experiment, he may have adjusted his tones and attitudes, and the expressions of his countenance, more completely to the sentiment and passion of the passages he is to deliver than the reader could possibly have done, and have accommodated them more completely to the rules and principles of grace, than is practicable to the spontaneous speaker: but what he gains in force and propriety he is in danger of losing in simplicity; and the mere reciter, however excellent, is more likely to extort applause than to awaken the genuine sympathies of the soul. From this view of the subject, the lecturer already cited concludes, that though the principles of English elocution, fundamentally considered, are the same, to which soever of these three modes of utterance they may be applied, yet the practical excellencies and obvious difficulties of each being peculiar, the student of elocution, whatever department be his ultimate object, should practise in all three, since reader, reciter, and spontaneous speaker, have each something to learn, from the other two, for the full accomplishment of his own particular branch of the art.

Another and more rational division of the art of elocution may be made from a consideration of the subjects to which it is applied, or the circumstances under which it is exercised. According to this principle, elocution may be considered as distinguishable into the following kinds, 1. The conversational; 2. The narrative; 3. The didactic; 4. The authoritative or judicial; 5. The argumentative; 6. The persuasive; 7. The declamatory and impassioned; relative to each of which some general rules may be laid down both with respect to voice and enunciation: as that in the first, the enunciation should be easy and familiar, the tone simple, the inflection limited, and the pitch of the voice but just so far beyond a whisper as to render it tuneable. In the second, the enunciation, though exceedingly simple, should be somewhat more precise and emphatic; the tone clear, unostentatious, and impressive; level, but not monotonous. In the third, both tone and enunciation should be strong, firm, and emphatic; which in the authoritative and judicial should swell to something like pomp, mingled with a degree of firmness that in effect should border on austerity, and with respect to modulation, almost on monotony. In the argumentative, clearness of voice and perspicuity of enunciation are the principal objects. In the persuasive, the tones should be mild, insinuating, and pathetic, the pronunciation remote alike from the affectation of sonorousness and of precision. In this, indeed, as in the seventh and last description of elocution, the enunciation should rather be subservient to the tone, (that is to say, to the feelings,) than the tone to the enunciation, as the object of the speaker is rather to be understood by the heart than by the understanding. In subjects and passages of strong passion and emotion, the enunciation should be occasionally accelerated and retarded; apparently wild and irregular, but obedient always to the changes of passion and sentiment; the modulation extensively varied, and the voice ranging through great varieties of softness, force, and vehemence, of acuteness and gravity, and the whole compass of expressive or reflective intonation.

The four great schools of elocution, or rather the four  
great

## ELOCUTION.

great theatres for the exhibition of that talent, are, the bar, the pulpit, the senate, and the stage; and before we take leave of the subject, something ought to be said on each of these. We shall consider them, therefore, in their alphabetic order.

*Elocution of the Bar.*—The style of elocution adapted to this profession, will best be understood by considering the objects to which the eloquence of the bar is principally to be directed. These are, 1. To demonstrate, by the elucidation of evidence, disputed facts; 2. To convince, by arguments, the doubtful judgment; 3. To influence by persuasion, or controul by declamation, the passions, the sympathies and moral feelings of those upon whom the decision of a cause may depend. For the first of these, we require an elocution distinguished by impressive distinctness, an unaffected deliberation, and collected coolness; an enunciation precise without formality, at once terse and familiar; a deportment candid, firm, and unassuming. For the second, we demand an emphatic perspicuity; an air of decisive, but modest confidence; an ardour not impetuous, but chastened and restrained, by all the decorums of circumstance and situation. For the last, the noblest, and most arduous of all the exertions of forensic eloquence, are required, a range of elocutionary expression, as various as the passions and emotions to be commanded; an insinuating mildness, a melting or a kindling pathos; the tone, the look, the whole manner, gesticulation and deportment, should occasionally assume the entire range of expressive variety, from the most conciliating sympathy to the deepest solemnity, and even, perhaps, on some occasions to intimidating boldness. The occasions, indeed, on which all that is here demanded can with propriety be exerted by the forensic orator, may but rarely occur; but when they do occur, the opportunities are decisive, and the reputation of the pleader, who is fully qualified to avail himself of them, is stamped for ever.

*Elocution of the Pulpit.*—The objects of clerical eloquence have been oratorically thus enumerated, “to inform the understanding even of the inapprehensive; to arouse the slumbering conscience; to regulate the moral feelings; to restore the social sympathies, which the disparities of fortune have but too much tendency to suspend; to restrain the fury of ambition, and check the mad career of voluptuous prodigality; to unlock the iron grasp of avarice, and expand the liberal palm to deeds of charity; to humble the towering insolence of pride, and disarm the uplifted hand of oppression and revenge; to infuse the spirit of benevolence into the heart of unfeeling obduracy; to breathe the sacred love of peace into the bosoms of the turbulent, and the mild spirit of forbearance and toleration into the soul of persecuting bigotry and prejudice.” How far all these objects are, practically, in the contemplation of every orator of the pulpit, this is no place to discuss; but if such be, in reality, among the proper objects of pulpit eloquence, it is obvious that all, and more than all, that we have demanded for the elocution of the bar, is requisite in this species of elocution also. Among the indispensable requisites of such elocution, are a familiar simplicity, insinuating and endearing; an impressive energy, stimulative and arousing; a pathos varied, characteristic, and descriptive; and a sublimity awful, elevating, and commanding. A mingled solemnity and enthusiasm should occasionally give an air of inspiration to the preacher, and his pronunciation, and all the particulars of utterance properly included in the term enunciation, should be full, sonorous, and oratorical, rather than loose and colloquial. At the same time, nothing is more to be avoided than any overmarked peculiarity or affectation, or than the vulgar vehemence, the bawling and vociferation, which are sometimes mistaken for energy and oratorical animation.

The modes of elocution in this profession, are those of reading, as applied to portions of the scriptures, or to set forms of worship; of sermon, which may be either read, (according to the general custom of the church of England,) recited, (as is usual among the preachers of the church of Scotland,) or delivered spontaneously, (that is to say, from notes or reflections previously digested, without actual composition,) as has been recommended by bishop Burnet, and as is practised by some of our separatists, and even by a very small number of our regular clergy; and of prayer. Of the first of these, it is only necessary to say, that the only circumstance in which it should differ from any other species of reading, seems to be, that it should be rather more solemn, and deliberate, from respect to the place and the occasion to which it is accommodated. In all kinds of reading, the style of elocution should accord with the subject, the tone and manner should harmonize with the language and sentiment; and as the subjects of scriptural and devotional reading are so exceedingly diversified, it follows as a consequence, that the style of the reader should be diversified as widely; and that nothing can be more inconsistent with the objects of clerical elocution than monotony. With respect to the three modes of delivering a sermon, this is not the place for discussing their respective claims of preference; and what has been already said of the application of the same common principles to reading, recitation, and spontaneous speech, and the different kinds of excellence most attainable in each, precludes the necessity of particular rules for them respectively. In prayer, a solemn prostration of manner, with a considerable mixture of enthusiasm, seems particularly required; and an especial avoidance of all those odd tricks and peculiarities, into which ministers are so apt to fall. But the further consideration of this subject belongs, properly, to the title GESTURE.

*Elocution of the Senate.*—As the eloquence of the senate is partly deliberative, partly controversial, and partly declamatory, it requires an elocution uniting almost all the principal requisites enumerated under the two preceding heads; and it admits, and even occasionally demands, a more impetuous warmth, a more rapid and vehement emotion, than in either of the former instances could be at all decorous. The sermons of Massillon might require, or, at least, their effect might be heightened by a denunciative severity, an awful austerity of manner, that should impress his audience with all the ideas and feelings of a supernatural agency; and under such circumstances the oratory of the pulpit might seem to have been carried, even above the heights, and beyond the force of senatorial and popular oratory; but it is in the senate alone, and the popular assemblies of the nation, that the orator is to hurry away the impetuous passions, and transport the hearer into absolute action; and there only are, of course, required the full thunders of elocutionary energy. But it is not only in the fervid tones of an impetuous declamation, that the senatorial elocutionist should excel; in the calm dignity of a well modulated cadence, and the polished grace and propriety of enunciation, he should also surpass; and in the easy urbanity of tone and euphony (when the stronger exertions of eloquence are not required) he should manifest, at once, the dignity of the statesman, and the elegance and refinement of the polite scholar. How little these circumstances, (almost all of them within the reach of a well directed education,) are attended to, is but too generally known; and in the humble state of modern oratory (as judged by its effects) the consequences may but too well be discovered.

*Elocution of the Stage.*—The critical object of theatrical representation is imitation. Its excellence is *verisimilitude*. It is a moving picture, that exhibits sounds as well as ob-

jects,

jects, and a part of whose pigments are the tones of the human voice. Its elocution, therefore, should be that of Nature—Nature in her highest perfection. Ideal nature, if you please; superior, in perfection, to any thing that individual nature ever exhibited, but in principle nothing deviating from unsophisticated reality. The harmony may be more perfect, the intonation something more diversified, the inflection and range of the voice rather more extensive, the utterance a little more emphatic, and some other graces and observances may be carried a degree further than ever was observable (or perhaps practicable) in spontaneous speech and real life; but still that spontaneity and reality must be the models; and the elocution, in all essential particulars, that would be unfit for the bar, the pulpit, or the popular assembly (so far as the difference does not arise out of the different sentiments to be expressed and passions to be indulged or excited) is unfit for the stage also. It should be remembered, however, that the drama deals in the extremes of passion and emotion; that its moral requires that it should exhibit those passions bursting all bonds of decorum, and triumphing over the restraints of reason. The player has frequently to exhibit the judgment under the domination of passions; and is even to represent the full malignity of the worst, as well as the imprudent excesses of the best passions of our nature; while the passions of the orator are always, in reality, (though not always in appearance,) to be under the controul of his judgment; and all the malignant and evil passions are to be suppressed, or kept out of sight, any otherwise than as they may be mentioned, or alluded to, in moral reprehension. Hence even the simplicity and truth of principle may, and must produce, occasionally, much apparent difference of effect; and the same exercise of judgment (for the judgment of the player must, in reality, still be paramount over his passion, though he be exhibiting the very reverse) that leads the orator, to temper and qualify, may induce the actor, to exaggerate the passion. It is in these exaggerations, however, that the art and mastery of the performer are most severely tried, and taste and judgment are alike imperiously requisite. They are necessary undoubtedly to the perfection of his art; yet the instant the exaggeration is apparent, disgust begins;—the instant the vulgar feeling of wonder is excited, the tragedian sinks to a level with the rope dancer; and many a time ought he to be overwhelmed with confusion, by those very plaudits to the attainment of which he has sacrificed all the finer touches of nature that might have secured the genuine applause of sympathy and emotion. But fully to attain, or even distinctly to comprehend, the higher excellencies of theatrical elocution, requires a very different course of preparation and study from what generally falls to the destiny, or enters into the apprehensions of the professors of this art. It is not in the science of the green room, the library of the prompter, and the technical knowledge of stage trick, to make a finished actor. To deliver language well, it is necessary fully to comprehend it, not loosely and colloquially merely, but grammatically, etymologically, and sympathetically; to detect the nicest shades of allusion and discrimination, and enter into the sentiment of the author; to realize the passion, where passion is, and the character, where the composition is characteristic. To excel in any species of elocution, therefore, demands some knowledge of general literature; to be a master of that elocution that should illustrate the fine passages of Shakespeare, will require a knowledge of our language which, fully possessed, would entitle the elocutionist to the rare and valuable character of an *English scholar*. But the sources of human passion must be studied also; human nature must be known, in the general, and in the particular, in all ranks and conditions, and

under all circumstances and associations. The perceptions must be diligently cultivated; the discriminative powers must be well exercised; feeling, keen, vigorous, varied feeling, must be cherished; and the imagination must be perpetually at work. For the development of the flexible powers of the voice, no pains well directed can be too elaborate, and the mind should comprehend, and the ear should perceive the delicacies and varieties of rhythmus, with all the subtle nicety of a poet. The actor so qualified will discard from his elocution all the pedantries alike of the convent and of the green room; all professional affections and prescriptive peculiarities; he will copy nature in such a style, that nature in her turn will copy him; and like the great actors of Greece and Rome, he will be worthy to give, while he receives, instructions to another Cicero or Demosthenes.

ELODES, in *Botany*, Adanson 444. (Elodea; Juss. 255.) A genus formed by Adanson of the *Hypericum Ægyptiacum* of Linnæus, on account of an oblong scale or appendage to the claw of each petal, considered by Linnæus as a sort of nectary, to which opinion he was probably led by the analogy of the nectariferous glands in his own *Hypericum Elodes*. We see no reason to separate the above plant from *Hypericum*, nor does Jussieu more than hint at the measure. See *HYPERICUM*.

ELODES is also used among the ancient writers in *Medicine*, for a species of fever, attended with profuse sweats.

ELOGIUM, ELOGE, a praise, or panegyric, bestowed on any person or thing, in consideration of its merit.

The word is Latin, but formed of the Greek εὐλογία, commendation; which is compounded of εὐ, well, and λέγω, to say, or speak.

The secretary of the Royal Academy of Sciences at Paris formerly composed the eloges of such members as died; and delivered them at the next public meeting of the company. Funeral orations are eloges of eminent persons deceased.

Extravagant and improbable eloges are of the greatest disservice to their own design; and do, in effect, diminish the person whom they pretend to magnify, and degrade him whom they profess to exalt. Any worthy man may pass through the world, unquestioned and safe, with a moderate recommendation: but when he is set off and bedaubed with rhetoric, and embroidered so thick, that you cannot discern the ground, it awakens naturally (and not altogether unjustly) interest, curiosity, and envy; for all men pretend a share in reputation, and love not to see it engrossed, or monopolized; and are therefore apt to enquire (as of great estates suddenly got) whether the person so commended, came honestly by it, and of what credit the person is that tells the story.

ELOHA, in *Scripture*, the singular of Elohi, one of the names of God. See ELOHI.

ELOHI, ELOI, or ELOHIM, one of the names of God: But it is to be observed, that angels, princes, great men, judges, and even false gods, are sometimes called by this name. The connection of the discourse assists us in judging rightly concerning the true meaning of this word. It is the same as Eloha; one is the singular, the other the plural. Nevertheless, Elohim is often construed in the singular number, particularly when the true God is spoken of; but when false gods are spoken of, it is construed rather in the plural. Calmet, *Diction. Bibl.* See *JEHOVAH*.

ELOI. See ELOHI.

ELOIGNED, in *Law*. See *ELONGATA* and *ELONGATUS*.

ELOINE, signifies to remove, or send a great way off. Thus it is said, if such as be within age be eloined, so that they cannot come to sue personally, their next friends shall be admitted to sue for them. *Star. 13 Ed. I. cap. 15.*

ELOME,

ELOME, a name given by some authors to orpiment.

ELON, in *Ancient Geography*, a town of Palestine, in the tribe of Dan. Josh. xix. 43.

ELONGATA, in *Law*, is a return of the sheriff, that cattle are not to be found, or removed, so that he cannot make deliverance in replevin. 2 Lil. Abr. 454. 458.

ELONGATION, in *Astronomy*, The angle under which we see the distance of a planet from the sun, reduced to the ecliptic.

Let S T (*Plate XII. Astronomy. fig. 104.*) be the distance of the sun from the earth, S L the curvate distance of the planet from the sun, the angle T S L equal to the difference of longitude of the planet P and earth T seen from the sun, called the commutation; the resolution of the triangle T S L, in which the two sides and contained angle are given, will give the angle at the earth S T L, called the elongation, and this being taken from the longitude of the sun, if the planet is to the east, or right of the sun, will give the geocentric longitude of the planet.

The triangle S L T may be resolved by the following rule: the least side is to the greatest as radius is to the tangent of an angle, from which  $45^\circ$  must be taken. The tangent of the remainder, multiplied by the tangent of half the sum of the unknown angles, gives the tangent of half their difference, which must be added to or subtracted from the half sum to trace the angle of elongation. This angle is the least of the unknown angles in the case of an inferior planet when the half difference must be subtracted; it is the greatest for a superior planet when it must be added.

It is sometimes useful to recollect the following proportions.

The sine of the commutation is to the sine of the elongation as the tangent of the heliocentric latitude is to the tangent of the geocentric latitude.

The sine of the elongation is to the sine of the commutation as the curvate distance of the planet from the sun is to the curvate distance of the planet from the earth.

It is at the time of the greatest elongations of the inferior planets Mercury and Venus, that they are usually seen to the greatest advantage. The greatest elongation of Venus was, according to Ptolemy, from  $45^\circ 25''$  to  $47^\circ 35'$ , and that of Mercury between  $16^\circ 8'$  and  $28^\circ 37'$ . According to our modern tables these numbers are, for Venus  $44^\circ 57'$  to  $47^\circ 48'$ , and for Mercury  $17^\circ 36'$  to  $28^\circ 20'$ .

ELONGATION is also used, by some authors, for the difference in motion, between the swiftest and the slowest of two planets; or the quantity of space, whereby the one has overgone the other; called also *superation*.

The swiftest motion of the moon, with regard to the sun, is called the elongation of the moon from the sun. We also say diurnal elongation, horary elongation, &c.

ELONGATION, as it relates to *Fortification*, is a term used to express that deviation from the immediately regular construction, which is derived from a polygon formed upon a circle, to one formed upon an ellipsis, or oval: when this happens, only two of the faces retain that construction and proportion which would appertain to the respective circles of which they would each form a part. In this we consider the ellipsis in question to be drawn upon two circles, and having a line passing through both their centres, as well as through the centres of the two retained faces; which necessarily are parallel. The two sides, or *elongated* arcs of the ellipsis, may be divided into any number of faces, according to the extent of the area inclosed; they are usually on the scale of the *greater* system, while the ends are on the scale of the *mean* system. Sometimes the elongation must be made so as to occupy a great extent of

front; in which case it may become expedient to throw forth a crown-work from the centre of the *elongated* arc, or line, in order to prevent the enemy from occupying any part of the esplanade sufficiently near to batter those works which may be rather weak for want of a flanking fire sufficiently powerful to impede the besiegers. These crown-works answer much the same purpose as advanced redoubts in front of a line of entrenchments, and scour the whole advance so completely, enfilading the assailants, as to render it peremptorily necessary to become matters of them before the lines can be carried. This will shew not only their ability, but the absolute necessity for constructing all such advanced defences, in that scientific manner which may render them untenable by the enemy, after being possessed by them, as well as perfectly incompetent to make any impression on the intrenchments, which would command them *in reverse*, that is, in their rear, and compel the enemy to quit. Crown-works being on a more important scale, require that every attention should be paid that their batteries should not bear upon any of the main defences.

The foregoing relates to regular works: for the irregular we have scarcely any thing like a defined rule; but it must always be held in mind, that the more the defences are elongated, the more they will require additional support, either from various lines of fortification one within the other, or from detached works, so situated as to defend the weaker parts. This necessity arises chiefly from the salient angles being rarely allowed to fall within  $90^\circ$ , lest they should plunge upon some other parts of the defences; whereas in all works formed upon a pentagon, hexagon, heptagon, or even an octagon, the angles of the bastions may be considerably reduced, and the ravelines equally so; it is owing to this that fortresses, on a large scale, not only admit, but require, numerous additional defences to fill up the several intervals between the exterior salient angles, or extremes of the defences, but to prevent the enemy from occupying positions favourable to their views.

We do not term works constructed in an irregular manner along the shores of a bay, or around a peninsula, *elongated*; they may be carried for miles without coming under that designation; it is only when a line of defence, and particularly fortifications, forming a figure either perfectly regular, or nearly so, are in every particular part extended, for the purpose of embracing more space, or conforming to any particular local circumstance, that we consider the term *elongation* to be applicable.

In *Tactics*, the term implies such an extension of the front as is produced artificially, without the aid of reinforcements. Thus, we draw up troops only two, instead of three, deep, for the purpose of elongating our front; which consequently thus becomes extended to half as much more as it formerly occupied in length. This is often necessary, but it certainly weakens the fire and the resistance throughout; besides, it prevents the casualties in the front from being so readily filled up, and is apt to leave gaps, or openings, through which the enemy's cavalry may make a charge.

Where it is absolutely necessary to retain a very firm front, yet to extend it so far as local means may allow, especially where it is principally intended to repel the enemy's horse, those parts of the line which may be most exposed by the evenness of the ground, &c. ought to be blocked by *abbatis*, that is, timber felled and laid in such a manner as should obstruct the passage of cavalry; behind these a few men should be dispersed to prick off any of the assailants who should attempt to cut an opening, or to drag away the trees, so as to obtain admission. Frequently trees can be cut down, but cannot be drawn away to any

chosen spot: in such case, their trunks and principal branches may be left, while their lesser boughs may be cut into stakes and palisades for the defence of other parts. The line will of course be elongated by such devices, while the more exposed parts may retain their effective strength. Where a convoy is in question, and that the attack upon it can be made only upon one long front, which cannot be entirely covered by the waggons, &c. then, placing the artillery in the most commanding situations, the infantry must be ranged in such manner as may *elongate* the defences, and keep the enemy in check. This will be peculiarly necessary where a neighbouring height must be cut off from the enemy's possession, though it could not be occupied by the defenders of the convoy without weakening and dividing them.

The elongation of an attack, is where only a small front is shewn at first, but is gradually extended so as to embrace a greater portion of the defences: thus, when after opening a battery upon a bastion only, other batteries are made to bear upon the curtain almost parallel thereto; in such case, we suppose only a bridge-head, or a *fleche* to exist, but no raveline. Likewise, when a column of infantry bearing down upon, and menacing only one particular point, suddenly deploys, and acts upon a greater extent of line, the attack is said to be *elongated*. But, in either case, the term does not apply to any additional force brought to act on the same point; it relates to extension merely.

**ELONGATION**, in *Surgery*, is an imperfect luxation; when the ligament of any joint is so extended, or relaxed, as to lengthen the limb, but yet not to let the bone go quite out of its place. See **LUXATION**.

**ELONGATUS**, **ELOIGNED**, a return of the sheriff that a person is conveyed out of his jurisdiction. See writ *de HOMINE REPLEGIANDO*.

**ELOPEMENT**, in *Law*, is when a married woman, of her own accord, departs from her husband, and dwells with an adulterer; for which, without voluntary reconciliation to the husband, she shall lose her dowry; nor shall the husband, in such case, be compelled to allow her any alimony. Stat. Westm. 2. 13 Edw. I. c. 34. See **DIVORCE** and **DOWER**.

“Sponte virum mulier fugiens, & adultera facta,  
Dote sua careat, nisi sponso sponte retracta.”

The word is formed from the Belgic, *Ee*, matrimony, and *loopen*, to run away.

However, mere advertising a wife in the Gazette, or other public papers, is not a legal notice to persons in general not to trust her; though a personal notice given by the husband to particular persons is said to be good. An action lies, and large damages are usually given, against a person for carrying away, and detaining another man's wife. See **FORCIBLE ABDUCTION** and **RAVISHMENT**.

**ELOPS**, in *Ichthyology*, a genus of abdominal fishes, the character of which, according to the Linnæan system, consists in having the head smooth; edges of the jaws and palate rough with teeth; gill-membrane with thirty rays, and armed on the outside in the middle with five teeth.

The genus *elops* is defined by Bloch as having the gill-membrane furnished with more than thirty rays, (specimens he examined exhibiting thirty-four,) and Boie admits there should not be less than thirty to constitute the genus. Bloch considers the bony shield or plate beneath the chin, and the dorsal fin being placed opposite the ventral, as essential characters of the genus.

The only species of this genus at present known is the Linnæan *elops saurus*; le lézard of the French writers.

Perhaps the earliest describer of this fish is sir Hans Sloane, who, in the second volume of his history of Jamaica, gives a figure and detailed description. He speaks of it under the name of *saurus maximus*, and acquaints us that it is called in Jamaica the *sein-fish*, or sea gally-wasp. “This fish (he observes) was about fourteen inches long, in the middle five inches round, and tapering to both ends; the mouth in both jaws had one row of small sharp teeth, and on the upper two more within, parallel to them, and a row of the same on the upper part of the cartilaginous tongue; three quarters of an inch from the end of the snout were the eyes, round, and grey; there were two *pinne post branchias*, two under the belly, one on the middle of the back, *post anum* another, and a forked tail; it was all over scaly, the back of a dark brown, and the belly of a white colour.” The species is found in various parts of the American seas; it was met with by Dr. Garden about Carolina, and communicated by him to Linnæus. The strong spine at each side of the tail is considered as a specific distinction of *elops saurus* by Linnæus, Gmelin, and others, but this must obviously remain a very doubtful character till another species at least of the same genus be discovered in order to ascertain whether such spines be not characteristic of the genus instead of the species.

It has been observed by writers that *elops saurus* bears some resemblance to a pike, or rather to a salmon; with the former it has no kind of affinity whatever, but on the contrary it is so closely allied to the *salmo* tribe that were it not from being destitute of the fleshy rayless fin, so uniformly observable on the lower part of the back in the salmon kind, we should be almost induced to refer it to that genus.

The head of *elops saurus* is without scales. The lower jaw rather longer than the upper. Both jaws, together with the tongue and palate, are armed with a vast number of small teeth. The eyes nearly vertical; the irides double, the inner one yellow, exterior red, and the pupil black; and the eyes partly covered with the skin of the head. The body of this fish is slender, and the scales large; the head yellowish, back blueish, sides silvery. The lateral line is straight. All the fins brownish; the exterior half of the pectoral fin, anterior part of the dorsal fin, and extremity of the tail blueish. The tail is much furcated, and divided in the middle by a distinct longitudinal stripe of black.

**ELOPS**, *Ελωψ*, in *Zoology*, the name of a serpent, otherwise called *elaps*.

**ELOQUENCE**, the art of speaking or writing well, so as to move and persuade. The term, however, in its greatest latitude, denotes that art or talent, by which the discourse is adapted to its end; “*Dicere secundum virtutem orationis. Scientia bene dicendi.*” Quintilian. In common conversation, however, the word eloquence is seldom used in such a comprehensive sense. But this definition exactly corresponds to Tully's idea of a perfect orator; “*Optimus est orator qui dicendo animos audientium et docet, et delectat, et permovet.*” Accordingly all the ends of speaking are reducible to four; every discourse or speech being intended to enlighten the understanding, to please the imagination, to move the passions, or to influence the will. When a speaker addresses himself to the understanding his aim is to inform, and to convince, for the former of which purposes the predominant quality is perspicuity, and for the attainment of the latter, argument. By the first we are made to know, and by the second to believe. The imagination is addressed, by exhibiting to it a lively and beautiful representation of a suitable object. As in this exhibition, the task of the orator may be said to resemble that of the painter, which consists in imitation, the merit of the performance

results entirely from the two following sources, *viz.* dignity, as well in the subject, or thing imitated, as in the manner of imitation, and resemblance, in the portrait or performance. This address attains the summit of perfection in the *sublime*, (which see,) or those great and noble images, which, presented to the mind in suitable colouring, expand, as it were, the imagination with some vast conception, and quite ravish the soul. The characteristic of the third species of discourse, or that which is addressed to the passions, is the *pathetic*. (See *PASSIONS* and *PATHOS*.) But the most complex and most important of all the kinds of eloquence is that which is calculated to influence the will and to persuade to a certain course of conduct. This is an artful mixture, of that which proposes to convince the judgment, and of that which interests the passions; and its distinguishing excellence results from these two, the argumentative and the pathetic duly blended. These, combining their force and acting in concert, constitute that *vehemence* of address, which is admirably fitted for persuasion, and has always been regarded as the supreme qualification in an orator. This animated reasoning was by the Greek rhetoricians termed *ênocheia*, and from signifying the principal excellency in an orator was used at length to denote oratory itself. Hence, as vehemence and eloquence became synonymous, the latter, in conformity to this mode of thinking, was sometimes defined "the art of persuasion." In order to persuade, which, though not the only object of eloquence, is the most important and for many reasons the most difficult, the most essential requisites are solid argument; clear method, a character of probity appearing in the speaker, joined with such graces of style and utterance as shall command attention to what he says. Hearers who exercise their understanding cannot be persuaded, without being convinced; but conviction and persuasion, though they are sometimes confounded, ought to be distinguished from each other. Conviction affects the understanding only; persuasion, the will and the practice. It is the business of the philosopher to convince a person of the truth; but it is the business of the orator to persuade him to act agreeably to it, by engaging the affections of the hearer. Conviction and persuasion ought always to accompany each other, but this is not universally the case; because the inclinations do not regularly follow the dictates of the understanding. The inclination may revolt, though the understanding be satisfied; the passions may prevail against the judgment. Conviction, however, is one avenue to the inclination, or heart; and it is that which an orator should first endeavour by his utmost efforts to gain; for no persuasion is likely to be stable, which is not founded on conviction. But in order to persuade, the orator must do more than produce mere conviction; he must duly consider the nature of man, and endeavour to act upon the different springs by which he is moved. He must address himself to the passions; he must paint to the fancy, and touch the heart; and hence, besides solid argument and clear method, all the conciliating and interesting arts, both of composition and pronunciation, enter into the idea of eloquence.

"We may distinguish," says Dr. Blair, (*Lectures*, vol. ii.) "three kinds, or degrees, of eloquence. The first, and lowest, is that which aims only at pleasing the hearer. Such, generally, is the eloquence of panegyrics, inaugural orations, addresses to great men, and other harangues of this sort. This ornamental sort of composition is not altogether to be rejected. It may innocently amuse and entertain the mind; and it may be mixed, at the same time, with very useful sentiments. But it must be confessed, that where the speaker has no farther aim than merely to shine and to please, there is great danger

of art being strained into ostentation, and of the composition becoming tiresome and languid.

"A second and a higher degree of eloquence is when the speaker aims not merely to please, but also to inform, to instruct, to convince; when his art is exerted in removing prejudices against himself and his cause, in choosing the most proper arguments, stating them with the greatest force, arranging them in the best order, expressing and delivering them with propriety and beauty, and thereby disposing us to pass that judgment, or embrace that side of the cause, to which he seeks to bring us. Within this compals, chiefly, is employed the eloquence of the bar.

"But there is a third and still higher degree of eloquence, wherein a greater power is exerted over the human mind; by which we are not only convinced, but are interested, agitated, and carried along with the speaker; our passions are made to rise together with his; we enter into all his emotions, we love, we detest, we resent, according as he inspires us; and are prompted to resolve or to act, with vigour and warmth. Debate, in popular assemblies, opens the most illustrious field to this species of eloquence; and the pulpit also admits it." See farther on the different species of eloquence under the article *ELOCUTION*. For the history of eloquence, and an account of the most distinguished orators; see *ORATORY* and *ORATOR*. Those who distinguish between eloquence and rhetoric represent the latter as proposing and explaining the theory, and the former as the practice of the art; but they are generally used indiscriminately for each other. See *ELOCUTION* and *RHETORIC*. On the subject of this article, see Campbell's *Philosophy of Rhetoric*, Blair's *Lectures*, vol. ii. and Cambray's *Dialogues on Eloquence*.

*ELORA*, or *ELLORA*, in *Geography*, a town of Hindoostan, in the vicinity of Dowlatabad, famous for its numerous pagodas, most of which are cut out of the natural rock. M. Thevenot, who has particularly described them, says, that for two leagues together nothing is to be seen but pagodas, in which are some thousands of figures. The sculpture of them he does not much commend; and we may apprehend, says major Rennell, that they are of early Hindoo origin. It should be recollected, that Deoghire, which stood in this neighbourhood, was the greatest and richest principality in the Deccan; and that the fame of its riches incited Alla to attack it in 1293; and these elaborate monuments of superstition were probably, as Rennell suggests, the offspring of that abundant wealth, under a government purely Hindoo. Sir C. W. Malet has given a particular account of these wonderful excavations, illustrated with drawings, in the sixth volume of the "*Asiatic Researches*." As to their origin or date no inquiry which he had been able to make afforded him satisfaction. He has no doubt, however, that they are the works of people, whose religion and mythology were purely Hindoo; and he adds, that most of the excavations carry strong marks of dedication to "Mahdew," as the presiding deity. Nevertheless he suggests, that the most northerly caves of Ellora, occupied by naked sitting and standing figures, are the works of the "Sewras" or "Juttees," who by the Brahmens are esteemed schismatics, and whose sect, called "Srawuk," is very numerous in Guzerat. The tenets, observances, and habits of the "Sewras" are peculiar, and in many points very different from other Hindus. Their adoration of the deity is conveyed through the mediation of "Adnaut" and "Parisnaut," the visible objects of their worship, personified as a naked man sitting or standing. This sect is supposed to be of a comparatively modern origin; and if this be the case, and the hypothesis of the dedication of the temples to their idol be admitted,

admitted, the limit of their possible antiquity will be assigned; but without ascertaining, or affecting, that of the others. As to the antiquity of these astonishing works, this writer has detailed two different accounts; one given by an intelligent Mahometan and another by a Hindu. The account of the first is said to have been derived from a person of acknowledged erudition. The second was deduced from a book, entitled "Sewa Lye Mahat," or the grandeur of the mansion of Sewa, *i. e.* Mahdew. The Mahometan reported, that "the town of Ellora was built by rajah Eel, who also excavated the temples, and being pleased with them, formed the fortrefs of Deoghire (Dowlatabad,) which is a curious compound of excavation, scarping, and building, by which the mountains were converted into a fort, resembling, as some say, the insulated temple in the area of the "Indur Subba" (one of the pagodas.) Eel rajah was contemporary with Shah Momin Araf, who lived 900 years ago." The Brahmen, on the other hand, said, "that the excavations of Ellora are 7894 years old, formed by Eeloo rajah, the son of Peshpout of Elichpore, when 3000 years of the Dwarpa Youg were unaccomplished, which, added to 4894 of the present Kal Youg, makes 7894." Our author inclines to the former opinion. He farther informs us, that the "Koond," or cistern, mentioned by the Brahmens, is still in excellent preservation, just without the town of Ellora; and the holiness of its water is even now in such high estimation as to render it a "Teerut" (pilgrimage) of great reputation and resort, under the appellation of "Sewalla Teeruit," or "Kond." There are many other excavations in a semicircular mountain, that commands a view of the fine valley of Ellora. In order to account for these extraordinary works, and the situation in which they were constructed, it should be considered, that the ancient Brahmens avoided the contamination of cities, and affected the purity and simplicity of rural retirement. In situations remote from observation, the imagination of their disciples probably enhanced the merits of their sanctity. Accordingly, to alleviate austerities, and to gratify the devout propensities of these holy men, became objects of pious emulation. Under the influence of this principle, the munificence of princes may have engaged to provide them retreats, which, sanctified by the symbols of their adoration, were at once suited, in simplicity and seclusion, to those for whom they were intended, and in grandeur to the magnificence of their founders. Thus power and wealth may have been combined, under the guidance of enthusiasm, to produce monuments, scarcely less extraordinary or less permanent, though less conspicuous and less known, than the pyramids of Egypt. Although some of these excavations are of very ancient origin, there are others, and particularly two, in a hill near a garden in the neighbourhood of Aurungabad, formed, as it is confidently asserted, by rajah Paur Sing, one of the Rajpoot Ameers of Aurungzebe's court, as a place of retirement, during his attendance on that monarch in his excursions to the neighbouring garden.

ELOTZ, a town of Russia, in the district of Orlof; 112 miles E.N.E. of Orel. N. lat. 53° 20'. E. long. 39° 14'.

ELOVKA, a town of Russia, in the government of Tobolsk; 16 miles W. N. W. of Tomsk.

ELOY, NICHOLAS FRANCIS JOSEPH, in *Biography*, was born at Mons, in the province of Hainault, on the 20th of September 1714, and died on the 10th of March 1788, having exercised his profession as a physician with great ability and disinterested humanity. He was a man of extensive learning, and great modesty, and much addicted to study; whence, notwithstanding his professional avocations, he was enabled to write upon a variety of topics, and his

publications are numerous. His first work, which was published in 1750, was a small treatise, entitled "Reflexions sur l'Usage du Thé." His next publication was an attempt at a history of medicine, arranged in the form of a dictionary, and entitled "Essai du Dictionnaire Historique de la Médecine Ancienne et Moderne," in two volumes octavo; which appeared in the year 1755; this work was afterwards greatly enlarged, by extending the different articles which it contained, and was published in 1778, in four volumes quarto, with the title of "Dictionnaire Historique de la Médecine Ancienne et Moderne;" to which, as our readers will have observed, we have been much indebted for information relative to the different medical characters, of whom we have already given a biographical account. Eloy likewise published, in 1755, a small volume, entitled "Cours Elementaire des Accouchemens;" and, a few years previous to his death, *viz.* in the years 1780 and 1781, he committed to the press two other essays, the first of which was entitled "Memoire sur la Marche, la Nature, les Causes, et le Traitement de la Dyssenterie;" and the other, "Question Medico-politique; si l'Usage du café est avantageux à la santé, et s'il peut se concilier avec le bien de l'état dans les Provinces Beligiques?" As a slight reward for the patriotic zeal manifested in this tract, the estates of Hainault presented him with a superb snuff-box, with this inscription, "Ex Dono Patriæ;" *the Gift of his Country.* He held the honourable office of physician to prince Charles of Lorraine. *Nouveau Dict. Hist.* &c. Lyon, 1804.

ELPHIN, in *Geography*, a post town of the county of Roscommon, province of Munster, Ireland, 75 Irish miles W. by N. from Dublin, and 7 miles S. from Carrick, on Shannon.

ELPHIN, a bishopric in Ireland, in the archi-episcopal province of Tuam. It dates its origin from St. Patrick, in the middle of the 5th century. It comprizes the greater part of the county of Roscommon, a large scope in Sligo and Galway, and a very little in Mayo; and is reckoned one of the most valuable of the Irish bishoprics. There are 75 parishes, which are formed into 29 benefices, and of these 26 have churches, which are the only ones in a tract of 420,150 Irish acres! The cathedral is a poor parish church, but the bishop's palace is a very good modern house, in the midst of an excellent demesne, and adjoining the small town of Elphin. Beaufort.

ELPHINSTON, WILLIAM, in *Biography*, a Scotch prelate and statesman, was born at Glasgow about the year 1431. He was educated at the University of his native place, and became distinguished for his proficiency in the learning of the times. He afterwards went to Paris, where he studied the civil and canon law, and likewise delivered lectures with great reputation for several years. Upon his return to Scotland he was promoted to church livings, and admitted a member of the king's council. He was, soon after this, appointed a joint commissioner with the bishop of Dunkeld and the earl of Buchan, in settling some disputes between the courts of Scotland and France. As a reward for the prudence and eloquence which Mr. Elphinston displayed on this occasion, he was, on his return, nominated to the bishopric of Ross; whence, about the year 1484, he was translated to the see of Aberdeen, and appointed, at the same time, to the chancellorship of the kingdom, an office which he held some time with the highest reputation; but when the troubles which took place between the king, James III., and his discontented nobility, had involved the kingdom in a civil war, he abandoned public state affairs, and confined

himself wholly to the duties of his bishopric. But, on the accession of James IV. his talents as a statesman were again called into exercise, and from this time his sovereign undertook no affairs of moment without his advice and concurrence. He died in 1514, at the advanced age of eighty-three, leaving behind him an excellent character; he was the patron of learning and learned men, and it is supposed, that by his influence the bull was obtained from the pope, for establishing a university at Aberdeen, with as ample privileges as were enjoyed by the most favoured seats of learning; and to his personal exertions and superintendance, it was chiefly owing that the building of King's college was undertaken and completed. To that foundation he proved himself a munificent benefactor during the remainder of his life; and, at his death, when he bequeathed large sums of money for its support. Gen. Biog.

ELPISTICI, *Ελπιστικοί*, among the Greeks, a sect of philosophers, who made hope the ruling passion of mankind.

ELRICH, in *Geography*, a town of Germany, in the circle of Upper Saxony, and county of Klettenburg; formerly the capital of the county; in which are some considerable manufactures; 6 miles N. W. of Nordhausen.

ELRICK, or EGELRIC ROAD, in *Antiquity*, was an ancient artificial road, made with great labour and expence through the fens, ten miles from Spalding to Deeping, by Egelric, abbot of Crowland, in the county of Lincoln, and afterwards bishop of Durham; who, as Ingulphus relates in his history of that monastery, raised, by means of wood and gravel, a causeway, or causey, for travellers, through the centre of a wild forest and deep marshes, called, after him, Egelric; or, by abbreviation, Elic-road. A part of it is still visible, lined with willows, between the river Welland, and the marshes north of Crowland. Gough's Translation of Ingulphus's History of Crowland.

ELS, in *Geography*, a town of Moravia, in the circle of Brunn, 32 miles W. of Olmutz, and 24 N. N. W. of Brunn.

ELSA, a river of Tuscany, which runs into the Arno, about a mile W. from Empoli.

ELSE, a river of Silesia, which runs into the Oder, near Oderburg.

ELSEN, a small town of France, in the department of the Roer, chief place of a canton in the district of Cologne, with a population of 304 individuals. But the canton contains 36 communes, and 12,239 inhabitants.

ELSEN, a town of Germany, in the kingdom of Westphalia, and bishopric of Paderborn; 2 miles W. N. W. of Paderborn.

ELSFLETH, a small town of Germany, in the duchy of Oldenburg; situated on the river Weser, where the duke of Oldenburg exacts a considerable toll from all vessels sailing up the river towards Bremen. At the peace of Lunenburg, the duke was offered an indemnity for this toll, with the view to favour the commerce of Bremen; but its produce is so important, that the duke would not consent to its abolition.

ELSGAU, a bailliage of Switzerland, being part of the bishopric of Basle, lying between the mountains and the Larg, and comprehending the town and bailiwick of Porentru, and 20 parishes.

ELSCHEIMER, ADAM, in *Biography*, a painter of very extraordinary talents, standing quite alone in the peculiar province of the list he adopted, *viz.* small pictures of landscapes with figures, and of small figures with landscape back-grounds. The figures being in some the prin-

cipal object, and occupying the largest portion of the space of the picture; and, in others, the landscapes being the most important. He was born at Franckfort; at what period, those who have written his life, differ much in stating; but the best authorities determine it to have been in 1574, and his death to have happened in 1620, so that he lived only 46 years.

He was at first a disciple of Philip Uffenbach, whom he soon excelled, and then determined to go to Rome, where alone he could acquire that high taste to which he aspired.

After some time spent in study of the fine works there exposed to his view, and an intimacy with many eminent painters, he fixed upon that style of art which has been mentioned as decidedly his own; in which no one had ever before exerted himself; and in which no one has ever since so highly excelled as Elsheimer.

That which renders his pictures so interesting is, the grandeur of style in which they are executed. Many of his figures partake so much of Raphael's best manner of character, of action, and disposition of the draperies, that if they were magnified, they would appear to be of that great master's own hand; and they have superadded a colour which is of a superior class; in the production of which, indeed, the smallness of their size was of considerable assistance to him; for it is by no means so easy to extend a full body of colour over a large surface, with equally pleasing variety of tone, and freedom of execution; and in it to separate and form the distinct parts as in a smaller one; and though it requires more neatness in the execution of the latter, it does not demand so free and so ready a hand to unite, to blend, and soften the various parts, and to give expression its full force, as in the former.

His pictures exhibit great attention to nature; particularly his perspective is very perfect, in lines, at least; and he not unfrequently chose very difficult things to manage: such as working with a short perspective distance, and sometimes placing his figures on the top of a hill, and suddenly losing the ground, till it is recovered again in a deep valley. His landscapes have, in general, the air of real views, and are finished with wonderful attention to general form, and beautiful scenery. Their colour is not always exactly that of nature, but as seen under a peculiar illumination, like the tone which Titian has adopted in his St. Peter Martyr; giving it an air of grandeur not to be obtained, perhaps, by the brighter hues of nature.

From the extreme care and excellence with which his works are finished, they were not, of course, in his short life, very numerous; and are rarely to be met with. The richest collection of them in this country is at the earl of Egremont's, at Petworth, in Suffex. There are ten pictures by him, eight of which are of one size, *viz.* about four inches high, by two and a half wide, or perhaps a little more. The subjects are, a St. Peter, St. Paul, St. John Baptist, Tobit and the Angel with a Fish, an old Woman and a Girl, an old Man with a Boy, and a Capuchin Friar, with a model of a convent in his hand. The figures in all these are about three inches high, yet their characters and expressions are just and excellent; and the drawing of their figures, and the draperies, in the best style of art. Another picture represents the interior of a brothel by fire and candle light, in which there are ten or more figures gaming, and indulging in the licentiousness of such a place, all exquisitely wrought; with some expressions that have never been surpassed, although the figures are not more than two inches and a half high. The last is Nicodemus's visit to Christ; but it is not of so good a quality as the others.

The subjects he chose were generally moon light or candle light pieces, which he painted with great lightness, spirit, and delicacy of touch, and with great knowledge of the chiaro-scuro, and excellent colour; and with such finish, that every part will bear the minutest inspection.

While he lived his pictures bore high prices, and they of course were greatly enhanced on his death; one of them is mentioned by Houbraken, representing Pomona, as having sold for 800 German florins. There are engravings from many of Elsheimer's pictures by his friend and benefactor, count Gaud; but they are in general too heavy and black, and have a flatness of effect, particularly in the trees, very unlike the originals; among them is one from his most famed picture, the Flight into Egypt, a moonlight. It is now, with two others of different subjects, in the National Museum at Paris.

Elsheimer, though thus endowed with taste and skill, was not the favourite of fortune. Notwithstanding he obtained great prices for what he did, yet his care in the execution of them, and the time they cost him to finish, were not so recompensed as to enable him to live and maintain a large family with comfort. As what he earned by his paintings would not find sustenance for himself and them, he fell into debt, and was cast into prison; the disgrace of which, though he was not suffered to remain long confined, is said to have preyed on his spirits, and hastened his dissolution. He was greatly regretted, and his works eagerly bought up, even by the Italians. The grand duke of Tuscany had several of them, and the world justly lamented the severe fortune of so extraordinary a genius, who deserved far more felicity than he was permitted to enjoy.

Elsheimer is highly celebrated, says another writer, for his careful pencil and extraordinary effects of light. Most of his landscapes are illumined by fire, or by moon, or torch light; and in them he has introduced small historical figures, which are highly appropriate to the scenes, and most exquisitely painted: yet his Aurora, of which there is an excellent print by count Gaudt, shews that bright and sudden light was not absolutely necessary to the display of his powers, and that he dipped his pencil in early dawn, with equal felicity.

The accuracy of his observation, and the retention of his memory were great, and the skill was scarcely less with which he introduced into his compositions, such picturesque incidents as he had once seen. Pilkington says that "it is impossible to conceive any thing more exquisite in painting than the productions of the pencil of Elsheimer; for whether we consider the fine taste of his design; the neatness and correctness of the drawing of his figures; the admirable management and distribution of his lights and shades; the lightness, the spirit, and the delicacy of his touch; or the excellence of colouring; we are astonished to observe such combined perfections in one artist; in whose works even the minutest parts will bear the most critical inspection, and the whole together is inexpressibly beautiful. He understood the principles of chiaro-scuro to the utmost perfection; and shewed the solidity of his judgment in the management of his subjects, which for the most part were night-pieces, by candle, or torch light," &c.

With these high claims to contemporary patronage, it was the fate of Elsheimer to fall a martyr to his own merits. Not affluence, nor even comfort, attended him in his professional pursuits. His family was numerous, and the great care with which his sensibility to the minuter beauties of nature prompted him to finish his pictures, occupied so

much time, that he was gradually overwhelmed with debts, and cast into prison. Being much respected, he was soon released; probably by his friend Gaudt, the engraver: but returned, spirit-broken, to his art, and survived not long. Posterity will reverence his professional merits, and regret his misfortunes.

Of artists of transcendent talent, it has been the frequent lot to receive from their contemporaries but a trifling earnest, either of the value of their works, or the extent of their fame: so blind is taste, with all its lofty pretensions, or so reluctant is human nature to recognise the claims of living excellence.

Among the most celebrated of his works, which are known through Europe, by the diffusion of count Gaudt's excellent engravings after them; may be mentioned his "Flight into Egypt," wherein he has contrasted the effects of fire and moonlight; two landscapes, in each of which he has introduced "Tobit and the Angel;" a "Cottage Door by Candle-light, with Ceres drinking from a Pitcher;" the story of "Baucis and Philemon;" the "Decollation of John the Baptist;" "Latona and her Sons, with the Lycian Peasants metamorphosed into Frogs;" and the "Death of Procris:" the two latter subjects were engraven in England by Magdalen Paff. Some of his most valued performances were late in the gallery of the grand duke of Tuscany. L.

ELSHOLTZIA, in *Botany*, so named by professor Willdenow in memory of a Prussian botanist, John Sigismund Elsholtz, who lived in the middle of the 17th century, and published a *Flora Marchica*, or catalogue of plants cultivated in the principal gardens of Brandenburg, printed at Berlin in 1663, in small 8vo. Willdenow mentions also a manuscript work on Horticulture by the same writer in his native tongue, preserved in the royal library of Berlin.—Willden. in *Römer Usteris Magazine*, fasc. II. 1. t. 1. Sp. Pl. v. 3. 59. Class and order, *Didynamia Gymnospermia*. Nat. Ord. *Labiata*, sect. 3. Juss.

Gen. Ch. *Cal.* Perianth of one leaf, bell-shaped, with ten furrows, and five oblong acute teeth; the orifice closed with hairs. *Cor.* of one petal, ringent; tube cylindrical, short, the length of the calyx: upper lip shortest, obtuse, concave, four-toothed, clothed externally with long white hairs; lower obtuse, straight, sharply crenate, externally clothed with hairs. *Stam.* Filaments four; the two uppermost shortest, lodged in the upper lip; the two lowermost in the under one: anthers roundish. *Pist.* Germens four, roundish, superior; style thread-shaped: stigma cloven. *Peric.* none. *Seeds* four, naked, brownish, in the bottom of the calyx. Willdenow.

Ess. Ch. Calyx tubular, five-cleft. Corolla ringent; upper lip four-toothed; lower longest, undivided, finely crenate. Stamens distant.

1. *E. cristata*. Willd. as above. (*Hyssopus ocymsifolius*; Lamarck *Encycl.* v. 3. 187.) "Spikes solitary, erect." Native of Siberia, about the lake Baikal. *Root* annual, fibrous. *Herb* with the habit of an *ocymum*, and a very fragrant scent, especially when rubbed after drying, compared by some to roses, but in our opinion more resembling the muscat grape. *Stem* a foot or more in height, square, leafy, with opposite branches. *Leaves* stalked, opposite, ovate, acute, serrated, light green, smooth. *Spikes* terminal, solitary, stalked, unilateral, consisting on one side of a double row of obovate, pointed, imbricated bractees, and on the other of three or four dense rows of pale lilac-coloured flowers. This plant is propagated by seed, with little trouble, in our gardens, but has more singularity than beauty in its aspect. The scent indeed renders it desirable.

2. *E. paniculata*. Willd. Sp. Pl. v. 3. 59. (*Hyssopus cristatus*; Lamarec. Encycl. v. 3. 187. Manám-podam; Rheede Hort. Mal. v. 10. 129. t. 65.) "Spikes panicled, reflexed." Native of moist places on the coast of Malabar. Lamarck, who had in his possession fine specimens of this plant from Sonnerat, assures us that the leaves are not alternate, as drawn in the *Hortus Malabaricus*, but opposite as in the preceding species, with which he rightly perceived its generic affinity. The chief specific difference seems to be in the inflorescence, which in the plant we are describing is panicled, each branch of the panicle consisting of a numerous series of reflexed spikes, shorter than in the former, with more oblique, unequally cordate, bracteas. Every part of this herb is said to exhale an agreeable aromatic odour. The root seems to be annual.

ELSIMBURG, in *Geography*. See HELSINBURG.

ELSINEUR, in Danish *Helsingør*, a handsome town of Denmark, in the island of Zealand, at the entrance of the Baltic, opposite the Swedish coast, 20 miles N. of Copenhagen. E. long.  $12^{\circ} 34'$ . N. lat.  $55^{\circ} 58'$ . The population amounts to between 6 and 7000 individuals. It derives its name from the Helsingers, an ancient Gothic colony, and is situated on the declivity of a hill, almost directly over-against Helsingburg, in the Swedish province of Scania. The passage is not above 4 English miles. The narrow arm of the sea, which joins the North sea and the Baltic, is called the Oeresund, or *Sound*, and is protected by the castle of *Cronenburg*, which see.

Till the year 1425, when king Erick of Pomerania bestowed on it the privileges of a city, Elsinour was but a small insignificant place. It has two churches, a grammar-school, several handsome private buildings, and a sugar-house. In 1753, a harbour was attempted, but the execution of the project was found impracticable. The roadstead, however, is excellent.

The principal trade of Elsinour is in wine and spirituous liquors; but it derives all its importance from the Sound dues, which, in times of peace, are paid at Elsinour by all vessels passing through the Sound from either the Baltic or the North sea. The custom-house, where these duties are paid, is a very fine building, and it is on account of this toll, that all nations trading in the Baltic keep a consul at Elsinour. The Sound dues are in proportion to the size of the ship and to the value of the cargo. They were originally a mere contribution to the expence of keeping light-houses on the coast.

The number of vessels of different nations that sailed through the Sound and paid the dues at Elsinour, was in

1768	-	-	-	6,30	vessels.
1778	-	-	-	8476	
1788	-	-	-	9224	
1792	-	-	-	12,114	
1798	-	-	-	19508	
1802	-	-	-	12,130	
1803	-	-	-	11,631	
1804	-	-	-	10,579	
1805	-	-	-	11,587	
1806	-	-	-	740	

And in the first three months of

1807	-	-	-	342	
------	---	---	---	-----	--

From which statement it appears, that the Baltic trade has been most considerable in the years 1792 and 1802, which both preceded the two late ruptures between England and France. See *SOUND*.

ELSNABBAN, a sea-port town of Sweden, in the province of Sudermania, on the coast of the Baltic; 32 miles E.N.E. of Nikioping.

ELSNER, JAMES, in *Biography*, a doctor of theology, was born, in 1692, at Saalfeld, in Prussia, and was destined by his father for trade, to which, however, he felt so strong a disinclination, that nothing could overcome it. He was accordingly sent to the university of Konigsberg, where he became private tutor to some young noblemen, and was afterwards appointed chaplain in the garrison to field-marshal count Alexander Von Dohm. He next went to Utrecht and Leyden, where he formed an intimacy with the most eminent literary characters of those cities. In the year 1719, he published a work on the delivery of the law on Mount Sinai, and shortly after the first volume of his "Sacred Observations on the New Testament." In the following year he left Holland, at the invitation of his Prussian majesty, by whom he was appointed professor of theology and the oriental languages at Lingen, having first taken his degree of doctor at Utrecht. From this place he was called to Berlin to restore the reputation of Joachim's school, which had fallen into much disrepute for want of proper discipline. Elsnor performed all that was required of him, and attained a high degree of respect, by the dignity and firmness of his manners. In the autumn of 1722, he pronounced an inaugural discourse on the obligation of uniting piety to learning; and immediately after this, he was chosen a member of the Royal Academy of Sciences. Other preferments were conferred upon him, and he was always very fully employed either as a preacher or an author; and, in 1742, he was appointed director of the class of the belles-lettres in the Royal Academy; and when the society was renewed in 1744, he retained the same office, and maintained the character which he had heretofore supported, as well by his attention to his academical duties, as by the learned dissertations with which he enriched the memoirs of the institution. He died of a fever on the eighth of October, 1750. His works are very numerous, and on various topics, but chiefly in theology. He published also, "A new description of the state of the Greek Christians in Turkey," in which he received very important assistance from Athanasius Dorostamos, who came to Berlin to collect money for the Christian slaves in England.

ELSTER, originally *Halfstrow*, in *Geography*, a small town of the kingdom of Saxony, in Upper Lusatia, on a river called the *Black Elster*, remarkable for its manufacture of knitted stockings.

ELSTERBERG, a small town of the kingdom of Saxony, in the circle of Voigtland, between some high hills on the river Elster, with an old ruined castle. It has a grammar-school, about 2000 inhabitants, and a flourishing manufacture of stuffs and woollen cloth.

ELSTERWERDA, a small town of the kingdom of Saxony, in the circle of Meissen, on the river Elster, with a fine hunting castle and a beautiful park. It has only 700 inhabitants; but is remarkable for a canal which was dug here in 1740, and by means of which it has a considerable timber trade to Meissen and Dresden.

ELSTOB, WILLIAM, in *Biography*, was born at Newcastle-upon-Tyne, in the year 1673. He was educated at Eton and Cambridge, but the latter place not being congenial to his health, he removed to Queen's college Oxford, where he was chosen fellow and tutor. In the year 1697, he took his degree of M. A., and in 1702 was appointed rector of the united parishes of St. Swithin and St. Mary Bothaw in London. He died in 1744, when he was only forty-one years of age. He published several works, and had collected materials for a history of Newcastle. He had likewise projected many literary designs, of which the most important,

important, was an edition of the Saxon laws, with great additions, together with notes of various learned men, and a prefatory history of the origin and progress of the English laws, down to the Conqueror and to Magna Charta. This great work was completed in 1721 by Dr. Wilkins, who deploras the loss which the literary world had sustained in the early death of Mr. Elstob. He intended also a translation, with notes, of Alfred's Paraphrastic Version of Orosius, of which his collections came into the possession of the late Dr. Teggé. This work was afterwards published by the Hon. Daines Barrington, with an English translation, who made use of Mr. Elstob's transcript. Biog. Brit.

ELSTOB, ELIZABETH, sister of the preceding, was attached to the same kind of pursuits, and was born at Newcastle in 1683. From a very early period she shewed a strong predilection for literary pursuits. She resided at Oxford during her brother's continuance at that university, and is described as having been the *indefessa comes* of his studies. She probably accompanied him to London, and assisted him in his antiquarian pursuits. To one of his publications, viz. the Homily on St. Gregory's day, she gave an English translation, and a preface in vindication of female learning. By the encouragement of Dr. Hickeys, she undertook a Saxon Homiliarium with an English translation, notes, and various readings, but only a few of the homilies were printed at Oxford in folio. In the year 1715, she published a "Saxon Grammar," the types for which had been cut at the expence of lord chief justice Parker, afterwards earl of Macclesfield. After the death of her brother, her circumstances were so very low, that she was reduced to the necessity of keeping a school at Evelham, in Worcester-shire. By the intercession of some friends, queen Caroline allowed her a pension of twenty guineas, which was paid very regularly till the death of that princess, when she was again reduced to great difficulties, and had recourse to education as a refuge from poverty. In 1739, she was received into the family of the duchess of Portland, where she continued till her death in the year 1756. Biog. Brit.

ELSYNGE, HENRY, was born at Battersea in 1598, and received his education at Westminster-school, and Christ-church college, Oxford. From the university he went to the continent, and spent seven years in foreign travel. Upon his return he was, through the interest of archbishop Laud, elected clerk of the house of commons, the duties of which office he performed with singular ability, and much credit. He acquired the esteem of all parties in the midst of much discord and faction, and kept his post under the long parliament till December 1648, when he chose to retire rather than take a part in the trial of the king. After this, he declined public business till his death in 1654. As an author his chief publication was entitled "The ancient Method and Manner of holding Parliaments in England." This was first printed in 1663. Anthony Wood supposed that it was chiefly transcribed from a MS. of the author's father, who was clerk of the house of lords, but there is no doubt it received many valuable additions from our author's own parliamentary experience. Mr. Elsyngé left a tract concerning proceedings in parliament, never published; and also other tracts and memorials. Biog. Brit.

ELTEN, in *Geography*, a small town of Germany, in the new kingdom of Westphalia, formerly a free imperial abbey, which was secularized at the peace of Lunéville, and given as an indemnity to the king of Prussia, who lost it again at the peace of Tilsit in July, 1807.

ELTERLEIN, a small town of the kingdom of Saxony, in the circle of the Ertzgebirge, situated between Annaberg and Grunhayn, with about 1000 inhabitants. It

is chiefly remarkable for the adjacent mines, which yield excellent magnesia and a very fine potters' clay for china. There is likewise a good manufacture of thread lace at Elterlein.

ELTHAM, a large village in the hundred of Blackheath and lathe of Sutton, in the county of Kent, England, consists of 256 houses, which are occupied by 1627 inhabitants. Its ancient name was Eald-ham, the old mansion or dwelling. John de Vesei, lord of Eltham, procured a grant of a market for this manor; and two other grants relating to it are extant among the records in the Tower. The market appears to have been discontinued in the time of James I., when the royal palace, the remains of which stand about two furlongs southward from the village, ceased to be visited by our kings.

Eltham palace was for several centuries a favourite retreat of the English sovereigns, to which, probably, its vicinity to the metropolis contributed, as well as the pleasantness of its situation. When it was originally built is unknown, yet it must have been prior to the year 1270, when Henry III. kept a grand public christmas here, accompanied by his queen and all the great men of the realm. In the next reign, Anthony Bec, the warlike bishop of Durham, obtained possession of it, and considerably improved it: he died here in 1311. Edward II. frequently resided here; and in the year 1315, his queen was delivered of a son in the palace, who was called John of Eltham, from the place of his birth. Edward III. held a parliament here in 1329, and another in 1375, when the Commons petitioned him to make his grandson, Richard de Bourdeaux, prince of Wales. Edward IV. was at a great expence in repairing the palace, where, in 1482, he kept his christmas in a very magnificent and costly manner, two thousand persons being daily fed at his charge. Most of the succeeding monarchs, to the time of Henry VIII., resided much in this palace; but on the rise of Greenwich it was gradually deserted. The change which it has undergone is exceedingly striking: formerly the abode of sovereigns, and the birth-place of princes, it is now a farm; and the beautiful great hall, where parliaments were held, and entertainments given in all the pomp of feudal grandeur, is now used as a barn for the housing and threshing of corn. The area, in which the buildings stand, is surrounded by a high stone wall, that has been partially repaired and strengthened by arches, &c. of brick, and a broad and deep moat, over which are two bridges, nearly opposite to each other, on the north and south sides. The hall is a most noble remain, measuring 100 feet in length, by 56 broad, and about 60 high. The windows have been extremely elegant, but are now bricked up. The roof is of timber, curiously wrought in the manner of that of Westminster-hall, and richly ornamented with finely carved pendants. Three parks, well provided with deer, were formerly connected with this palace: in the largest, which includes an area of two miles in circumference, stands a respectable mansion, called Eltham lodge. Haisted's History of Kent.

ELTMAN, a town of Germany, in the circle of Franconia, and bishopric of Wurzburg; 8 miles W.N.W. of Bamberg, and 40 E.N.E. of Wurzburg.

ELVAS, formerly *Jelves*, a town and bishop's see of Portugal, in the province of Alentejo, containing three parish churches, seven convents, two hospitals, and 12,500 inhabitants, including the district, in an open and fruitful territory, 18 leagues N.E. of Evora, and six W. of Badajoz, in Spain. It has a castle on an eminence, and is commanded by Fort la Lippe, a new and strong fortification on the top of a hill. Here is a remarkable aqueduct, supported

ported in some places by three arches one over the other; the streets are narrow, irregular, and dirty; and the houses are indifferently built. At some distance from the town the country is bleak and barren. N. lat.  $38^{\circ} 44'$ . W. long.  $7^{\circ}$ .

ELVÆ. See ELFS.

ELUDING, the act of evading, or rendering a thing vain, and of no effect: a dextrous getting clear, or escaping out of an affair, difficulty, embarrassment, or the like.

We say, to elude a proposition, &c. The design of chicanery is, to elude the force of the laws; this doctor has not resolved the difficulty, but eluded it. Alexander, says the historian, in cutting the Gordian knot, either eluded the oracle, or fulfilled it: "Ille nequicquam luctatus cum latentibus nodis, Nihil, inquit, interest, quomodo solvatur; gladioque ruptis omnibus loris, oraculi sortem, vel eludit vel implevit." Q. Curt. 13.

ELVEN, in *Geography*, a small town of France, in the department of Morbihan, chief place of a canton in the district of Vannes, with a population of 3829 individuals. The canton contains five communes and 9136 inhabitants, upon a territorial extent of 220 kilometres.

ELVERDINGHE, a small town of France, in the department of the Lys, chief place of a canton in the district of Ypres, with 2729 inhabitants. Its canton has a population of 9057 individuals dispersed in 9 communes, on a territorial extent of  $112\frac{1}{2}$  kilometres.

ELVERS, in *Ichthyology*, an English name for a small sort of eels, caught in some parts of the kingdom, particularly about Gloucester and Tewksbury. These are, in reality, young eelers, or sea-eels. They get up into rivers while very small, and as they precede the shads, it is conjectured that they supply them with food. They are taken in prodigious numbers in the rivers, in dark nights, by a kind of sieve made of hair-cloth, fixed to a long pole, and are esteemed a very delicate food. Willughby.

EL-VISO, in *Geography*, a well built town of Spain, in the province of New-Castile, and district of La Manche, containing a parish church, a convent, a palace of the marquis D'El-Viso, and 3500 inhabitants, about 20 leagues S.W. of Alcaraz; and 13 S.S.E. of Ciudad Real, situated in a fertile plain, producing corn, wine, and fruits.

ELVIUS; PETER, in *Biography*, was born at Upsal in 1710, and applied himself in early life to the study of mechanics, under able masters. In the year 1738, the royal college of Mines entrusted him with the care of its collection of machines. His own knowledge enabled him to construct a fulling mill on new principles. In 1743 he undertook, with M. O. Hamren, a tour through the kingdom of Sweden, to examine where the best situations could be obtained for works to be driven by water; and on this occasion he drew plans of those places which seemed most convenient for the purpose. For this service he obtained a place in the academy of Upsal, and applied himself to the calculation of chances and probabilities, which led him to consider the existing bills of mortality, and the means for rendering them more accurate and useful. He was a diligent observer of the heavens, and on the island of Huen searched out the ruins of the residence of Tycho Brahe, and made some celestial observations amidst the remains of Uraniburg. He died at the early age of 38, on the 27th of Sept. 1749, and the Academy of Sciences, to which he had been the secretary, caused a medal to be struck in honour of his memory. Gen. Biog.

ELUL, in *Chronology*, one of the Hebrew months, answering partly to our August and September. There are but nine and twenty days in it. It is the twelfth month

of the civil year, and the sixth of the ecclesiastical. Upon the seventh or ninth day of this month the Jews fast, in memory of what happened after the return of those who went to view the promised land. Numbers, xiii. xiv.

Upon the twenty-second of this month, the festival of the xylophori was observed, when wood was carried to the temple. Selden says, that it was celebrated on the eighteenth day of the month Ab. On the twenty-sixth of the same month, the dedication of the walls of Jerusalem by Nehemiah was commemorated. Joseph. lib. ii. cap. 17. p. 811. Nehem. xii. 27, &c. Calmet, Diction. Bibl.

ELVO, in *Geography*, a river of Italy, which runs into the Sesia, 2 miles N. of Vercelle.

ELUSA, in *Ancient Geography*, a town of Palestine, in Idumæa, W. of Jordan, according to Ptolemy. This town was once an episcopal city, and it is placed by P. Hardouin in the third Palestine.

ELUSA, called also *Eluse*, and *Civitas Elusatium*, a town of Gaul, was formerly the metropolis of Novempopulania, and maintained that rank till the eighth century. But upon its destruction by the Normans, the see of Auch was advanced to the rank of Metropolitan. Some remains of this place retain the name of Ciutat near Euse.

ELUSATES, the inhabitants of Elusa, who occupied the N.W. district of Armagnac. Cæsar mentions them, and places them between the Tarusates and the Garites.

ELUTRIATION, or *washing over*, is a method of separating substances of different specific gravities from each other by means of water. For this purpose the mixture is stirred about briskly in a vessel full of water, and when the heavier particles have again fallen to the bottom, the water, still turbid with the lighter ones that are as yet suspended, is poured off into another vessel, to the bottom of which they, in a short time, subside. By this simple method a skilful person will separate from each other three or four substances with great exactness.

ELUVIES, in *Geology*, is a term used by Mr. Parkinson, (*Organic Remains*, i. 275.) and some other writers, to express the supposed ruins of the antediluvian earth, effected by the Noachic deluge, but which it is presumed by others, from the Mosaic account of that miracle, did not destroy the existing vegetable productions or the fish, and much less therefore could it have effected the universal disintegration of mineral substances, on which Dr. Woodward's and some other theories are built. Besides, the animal and vegetable substances, which are found imbedded in the supposed post-diluvian strata, are none of them of the species, which, by the established modes of generation, have been handed down to us, immediately from those individuals of each species which Noah preserved in the ark, when the rest were drowned by the flood.

ELUXATIO, (from *eluxo*, to put out of joint,) a dislocation.

ELWAD-AD, in *Geography*, a town of Arabia, in the country of Yemen; about 40 miles nearly W. of Chamir. N. lat.  $16^{\circ} 16'$ . E. long.  $42^{\circ} 30'$ .

ELWALL, EDWARD, in *Biography*, was born at Sedgley, near Wolverhampton, in Staffordshire. At Wolverhampton he settled in business, and acquired the reputation of honesty and great integrity in his dealings. As a politician, he was distinguished as the zealous assertor of the civil and religious rights of the people, and as a vigorous supporter of the Hanoverian succession. He was of a serious and inquisitive turn of mind, and never hesitated to proclaim his sentiments on any subject that he deemed important. He considered the fourth commandment as binding on all generations, and not only wrote in defence of the opinion, but

while in business, constantly shut up his shop on the seventh day, and opened it on the first day of the week; hence he was stigmatized as a Jew. About the year 1714 he became distinguished as an Unitarian, and published "A true Testimony for God and his sacred Law, being a Defence of the first Commandment of God, against all Trinitarians under Heaven." This drew on him the resentment of the neighbouring clergy, who ceased not to pursue him with their enmity, till they procured an indictment against him for heresy and blasphemy; on which he was tried, without having had a copy of his indictment, before judge Denton about the year 1726, at Stafford assizes. He pleaded his own cause, and vindicated the principles which he had embraced with a firmness and presence of mind, said to have been rarely equalled in modern times, and with complete success, for a respectable and honest jury, under the direction of an upright judge, acquitted him. Mr. Elwall was not daunted by the obloquy and prosecution which his first piece had drawn on him from defending with freedom the sentiments for which he had suffered, but published several other tracts, having the same tendency. After his trial he removed to London, and became a member of the seventh-day Baptist church at Mill-yard, Goodman's fields. In the latter part of his life he frequently attended the religious assemblies of the quakers, and was sometimes admitted to speak among them. He died in London at an advanced age, with an unspotted reputation, about the year 1745. He had not enjoyed the advantages of a learned education; but his natural abilities, and good judgment, were such as rendered his conversation agreeable to persons in the higher ranks of society, by whom he was known, and respected, on account of his ardent attachment to the house of Hanover. Speaking of himself, his principles, and conduct, he says, "I have been a sturdy and strenuous friend to my royal friend George these forty years and upwards, ever since the nation happily settled the crown in his illustrious family; and many a stately Jacobite and Tory have I silenced by dint of argument, and brought to the ground by dint of fist, yet generally in self-defence, and not to convince his judgment." He was a man of inflexible integrity and of extensive charity, as well as of fervent piety.

ELWANGEN, in *Geography*, a small town of the kingdom of Wurtemberg, 18 miles S.E. of Halle, in Suabia, and 30 S.W. of Anspach. It was formerly a rich abbey of the German empire, whose prelate ranked as a prince, and voted in the college of princes. At the peace of Lunéville it was given to Wurtemberg as an indemnity for the territory which its sovereign was forced to cede to France on the western shore of the Rhine.

ELWY, Britain, the name of two rivers in Wales, one rising near Gwythrin, in the west part of Denbighshire, in North Wales, runs eastward for some miles, then suddenly turning northward above St. Asaph, passes by that city, and falls into the Clwyd, about three miles below it. Another river of the same name rises in the mountains to the northward of Capelton Ybedyddier, in Glamorganshire, South Wales; and running in a south-easterly direction passes Hensfall park, St. Fagan's, &c. and meeting the Taf, at the Embochure, near Penarth-point, forms Penarth harbour.

ELXAI, in *Biography*. See ELCESAITES.

ELY, ISLE of, in *Geography*, a tract of land so called, is situated in the northern part of Cambridgeshire, England, and was formerly surrounded by waters; but, in consequence of the vast improvements made by draining the fens, &c. it is now merely known by the name of an island. The whole district, called the isle of Ely, extends from the

bridge at Tyd on the north, to Upwere on the south, 28 miles in length; and from Abbot's or Bishop's Delf on the east, to the river Nene, near Peterborough, on the west, 25 miles in breadth: and includes several considerable towns and villages, of these the principal place is.

ELY, which, though far from populous, claims, as being the see of a bishop, the appellation of a city. It is situated on a small eminence near the river Ouse, and owes its origin to the establishment of a monastery here, A.D. 673, by Etheldreda, daughter of Anna, king of East-Anglia. After her death, in 679, the government of the abbey successively devolved on her sister Sexburga, queen of Kent; Ermenilda, queen of Mercia, daughter of Sexburga, and the princess Werburga, her grand-daughter, all of whom were, with the foundress, for many centuries considered as saints. A town gradually arose about the monastery; and both remained in peace and security till the year 870, when this place of monastic retirement was discovered by the Danes, who invaded the isle, and, though at first repulsed by the bravery of the inhabitants, returned in greater numbers, and overcame every defensive effort. They put the religious to the sword, set fire to the church and other buildings, and departed, loaded with the spoil, not only of the town and monastery, but also of all the neighbouring places, whose inhabitants had deposited their valuables here for better security. Some of the inmates of the monastery, who had escaped the massacre by flight, returned a few years afterwards, and commenced a college for secular clergy, which continued till 970, when the monastery was restored to its former establishment by Ethelwold, bishop of Winchester, under the patronage of king Edgar, who, in consideration of a large sum paid by the bishop, gave up to the convent the jurisdiction of the isle, which after the Danish massacre had been annexed to the crown. Bishop Ethelwold bestowed large benefactions on the abbey, which now consisted of regular monks of the order of St. Augustine. Brithnoth, the first abbot, exerted himself to complete the repairs of the church. The abbey continued to prosper till the conquest: its privileges being previously augmented and confirmed by Canute, and again by Edward the Confessor, the latter of whom had received his education within its walls. During the confusion which ensued on the Norman invasion, the abbey was deprived of many estates; and Thurstan the abbot, fearing that its whole possessions would be seized by the Conqueror, resolved to support the interest of Edgar Atheling, in which he was joined by several English nobles, who were determined to defend their country from the dominion of William, whom they regarded as an usurper. A vigorous, and, for some time, effectual resistance was made; but at length, the abbot having seceded from the confederacy, the superior prowess of the Norman soldiers prevailed. Great numbers of the English were slain in battle; and many of those, who were made prisoners, were cruelly mutilated; some having their eyes put out, and others their hands and feet cut off, that they might remain living monuments of the Conqueror's vengeance, and become a terror to such as disputed his authority.

A bishop's see was established here in 1107, and Henry, bishop of Bangor, was appointed the first diocesan. This prelate procured many gifts and privileges for his bishopric, and a grant of a fair for the city, to continue for seven days. The king granted a mandate to make an equal division of the abbey estates, between the prelate and the abbot, but the former contrived to retain a full third of the possessions more than he was entitled to. On the surrender of the monastery to Henry VIII. that monarch granted his letter-patent, dated September 10, 1541, to convert the convent

tual church into a cathedral, by the title of the Cathedral Church of the Undivided Trinity; the establishment for the performance of divine service to consist of a dean, a priest, and eight prebendaries, with other ministers: the dean and prebendaries to form a body corporate. The bishop of Ely possesses the rights of a lord of a county palatine, and is sovereign within the isle, where all causes are heard and determined by a judge of his appointing, who holds assizes, gaol delivery, and quarter sessions.

The cathedral is the workmanship of very different periods, and displays a singular admixture of the Saxon, Norman, and English styles of architecture; yet, notwithstanding the dissimilarity of its parts, it must, when considered as a whole, be regarded as a very magnificent structure. The north and south transepts, which are the oldest parts, were erected in the reigns of William Rufus and Henry I. Here the arches are semi-circular, as well as in the nave, which was begun in the reign of the latter monarch, and completed before 1174. Between this period and the year 1189, bishop Rydel erected the great tower at the west end, which was anciently flanked on the north side by a building of the same kind as that on the south: but this either fell or was taken down, and another building begun in its place. This was never carried higher than 12 or 14 feet. The interior view of this tower is particularly beautiful, it being decorated with small columns and arches running round in several stories, and lighted by 27 windows. The lower part was repaired, and new cased with stone, in the middle of the 15th century. The handsome vestibule at the entrance, formerly called the Galilee, was built about the year 1200, by bishop Eustachius. The foundation of the elegant structure which was originally the presbytery, but now forms the choir, was laid by Hugh Northwold, the eighth bishop, in the year 1234, and finished in 1250. The three most western arches were destroyed by the fall of the lofty central tower, in the night of the 12th of February, 1322. To prevent the recurrence of a like accident, Alan de Walsingham, sub-prior of the convent, and sacrist of the church, a person eminently skilled in architecture, designed and erected the present magnificent octagon, which is supported on eight pillars, and terminated by a lantern. The capitals of the pillars are ornamented with historical carvings, representing the principal events in the life of Etheldreda. This octagon is probably unequalled by any of the kind: the stone work was completed in six years, and the wood work raised thereon, and covered with lead, in about 15 years. The whole was perfected in the year 1342, at the expence of 240*l.* 4*s.* 11*d.* The three arches eastward of the octagon were rebuilt about the same period, by bishop Hotham, and are very much embellished. At the east end of the north aisle is a sumptuous chapel, erected by bishop Alcock, who died at his castle at Wisbech, in 1500. His tomb, with his effigy lying thereon, but much defaced, is placed under an arch of stone on the north side. In the south aisle, and in some respects corresponding with the former, but much superior in its embellishments, is another chapel, which was erected by bishop West, about the year 1530, and is highly enriched with ornaments and elegant tracery, &c. Both these chapels were greatly dilapidated by the enthusiastic reformers who sprung up during the civil wars, and seem to have had an invincible antipathy to every religious edifice that displayed taste and elegance.

The extreme extent of the cathedral, from east to west, is 535 feet; but the interior length is only 517. The length of the transept is 190 feet, the height of the lantern over, 170. The extreme height of the western tower

270, and the tower on the south wing of the latter 120. The length of the nave is 203 feet, and the height of the roof over it 104. The height of the eastern front to the top of the cross is 112 feet. Near the east end of the cathedral, on the north side, is St. Mary's chapel, now Trinity church; it having been assigned to the use of the inhabitants of that parish soon after the Restoration, by the dean and chapter. This elegant structure was commenced in the reign of Edward II. and is one of the most perfect buildings of that age. The shape is an oblong square; the interior length being 200 feet, the breadth 46, and the height of the vaulted roof 60. This building has neither pillars nor side aisles, but is supported by strong buttresses, surmounted with pinnacles. The spaces over the east and west windows were formerly decorated with statues, and a variety of well-executed sculpture: and the interior was embellished with niches highly carved, and enriched with statues, ornamental foliage, and flower-work. This edifice was built at the charge of the convent by John de Wisbech, one of the monks, and Alan de Walsingham, who erected the octagon. The first stone was laid by the latter on Lady-day, 1321. The cloisters, and other buildings belonging to the monastery, have been long since demolished; with the exception of the refectory, which has been converted into the deanery; and an elegant little chapel built by prior Crauden, now used as a granary, adjoining to it.

The principal charitable benefaction for the use of the poor of Ely is vested in the churchwardens, and arises from estates in the neighbourhood, bequeathed by — Parson, about the year 1425. Here is also a free-school, supported by the dean and chapter; and a charity-school for twenty-four boys, who are educated and clothed by the income of an estate bequeathed by Mrs. Needham about 1740. The police of Ely is regulated by the magistrates, who are appointed by the bishop, and are justices of the peace within the isle. These meet for the dispatch of business every market-day, which was altered in 1802 from Saturday to Thursday. This city is the only one in England not represented in parliament. Many of the houses are of stone, and some of them have an ancient appearance. The streets are irregular, and, with the exception of the principal one, neither lighted nor paved. The population, as ascertained under the late act, was 3713; the number of houses about 700. The chief employment of the inhabitants is gardening, which is carried on in this neighbourhood to a great extent. Cambridge, St. Ives, and even London, receive considerable supplies of vegetables from this place. Great quantities of strawberries are also reared here, and some other fruits; but these are chiefly conveyed in barges to Lynn, and carried thence by the vessels employed in the coal trade to Newcastle-upon-Tyne, and other places in the north of England.

The Rev. James Bentham, author of "The History and Antiquities of the conventual and cathedral church of Ely," was a native of this city. Some account of this gentleman has already appeared in this work. (See BENTHAM.) An interesting and well written account of Ely cathedral has recently been published by the Rev. Mr. Miller, of this place. See also Lysons's *Magna Britannia*, vol. ii.

About one mile from Ely is Tatterfall-hall, which derived its name from the late Mr. Tatterfall, of sporting memory, and is now possessed by his son.

ELY, *Elie*, or *Ellie*, a parish of Fifeshire, in Scotland, within which is an ancient royal borough of the same name. This is situated close to the sea, on the southern shore of the Frith of Forth, where there is an excellent harbour, much resorted to by "wind-bound vessels." Seven square-

square-rigged vessels, carrying 1000 or 1100 tons, belong to it, and are employed in foreign trade. Vessels of large size are built here; and in the town are some manufactories for checks, bed-ticks, and ropes. Near the shore rubies have been discovered. Contiguous to the town, in the face of Kinraig rocks, is the cave of Mac-Duff, in which it is related that Mac-Duff retreated from Macbeth and his followers. Malcolm granted many privileges to this town. Sinclair's statistical Account of Scotland.

ELYMAIS, in *Ancient Geography*, or, as it is called by Strabo, *Elymatis*, a province of Persia, lying between the rivers Eulæus and Oroates, and extending from the confines of Media to the Erythræan sea, or Persian gulf. It was formerly divided into three great districts, viz. Mesabatene, Gabene or Gabiene, and Carbiana, and containing the following cities, viz. Seleucia or Soluce, on the banks of the Hedypos or Hedyppus, which Strabo calls a great city, Safirate, at a small distance from mount Calyrus, Badaca, on the Eulæus, and Elymais, the metropolis of the province, famous for a rich temple consecrated to Diana, which Antiochus Epiphanes attempted to plunder, but he was obliged by the inhabitants to retire in disgrace to Media. This temple was afterwards plundered by one of the Parthian kings, who found in it, as we are informed by Strabo, 10,000 talents. In this country there was also a very rich temple consecrated to Jupiter Belus, which Antiochus the Great attempted to plunder, but lost his life in the attempt. The country of Elymais was inhabited, according to Pliny, by the following nations, viz. the Oxii, or Uxii, Mizæi, Parthusi, Mardi, Saitæ, Hyi, Cossæi, Parataceni, and Messabatæ. The Elymæans were a powerful people, inured to the toils of war, skilful bowmen, and never subdued either by the Syro-Macedonian, or Parthian kings, but governed by their own princes. If we may depend upon the authority of Strabo, the rise of this kingdom may be dated from the downfall of the Persian monarchy, for the ancients are agreed that the Elymæans were subject to the kings of Persia; and if they never submitted to the Syrian yoke, they must have been first governed by their own princes, either in Alexander's life-time, or soon after his death. Nothing is known of their kings, but that they assisted Antiochus the Great in his wars with Rome, but afterwards cut him off in defence of their temple. They afterwards engaged, under the conduct of their king, in a war against the Babylonians and Susians, in which they were assisted by the Cossæans with 13,000 archers.

ELYMAIS is also a name given by some writers to the city of Persepolis.

ELYMI, or HELYMI, a people who inhabited the N.W. part of Sicily, about the river Crimisa, where were situated the towns of Ægesta or Acasta, Erice and Entella.

ELYMIA, a town of Greece, in the Peloponnesus, placed by Xenophon towards the towns of Mantinea and Orchemene.

ELYMIOTÆ, a people of Macedonia, who occupied a plain almost surrounded by mountains, towards the source of the river Aliacmen, according to Ptolemy. They had to the N. W. the country of the Lyncestes, to the N. E. Emathia, to the S. E. the Pelasgiotide, and to the S. W. Pelagonia.

ELYMNIUM, one of the names of the island of Eubœa.—Also, a town of Macedonia, on mount Athos.

ELYMUS, in *Agriculture*, a term signifying lime-grass, a genus of grasses which are of but little use to the farmer, except in protecting the loose sandy banks on the sea-shores, in different parts of the island; and for which purpose the following sort is the most useful.

ELYMUS *Arenarius*, sea lime-grass, which is a kind of grass that, with the sea reed, helps very much, according to the opinion of Mr. Sole, to sustain and keep up the loose sand-banks on the borders of the sea, from the destructive effects of the tides.

ELYMUS, in *Botany*, ελυμος; of Dioscorides, from ελυω, to fold up, alluding to the sheath which incloses the spike or ear of some species. This etymology applies at least to the Millet or Panick, supposed to be the ancient ελυμος; but Linnæus has adopted the name for a new genus of his own, akin to *Hordeum* and *Triticum*, to which it is less suitable. Linn. Gen. 39. Schreb. 54. Willd. Sp. Pl. v. 1. 467. Juss. 31. Sm. Fl. Brit. 152. Mart. Mill. Dict. v. 2. Class and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Common receptacle elongated into a spike. Perianth lateral, aggregate, consisting of two lanceolate glumes to each spikelet. *Cor.* of two valves; the outer one largest, pointed, awned; the inner concave, emarginate, finely fringed. Nectary a pair of oblong, acute, fringed scales. *Stam.* Filaments three, capillary, very short; anthers oblong, cloven at the base. *Pist.* Germen turbinate; styles two, divaricated, short; stigmas feathery. *Peric.* none, except the permanent corolla. *Seed* solitary, linear, convex at the back, concealed by the glumes.

Ess. Ch. Calyx lateral, aggregate, of two valves, containing many florets.

A genus of large coarse rigid grasses, for the most part perennial, with long creeping roots. This last quality renders the *E. arenarius*, Linn. Sp. Pl. 122. Sm. Engl. Bot. t. 1672. Knapp. t. 108, particularly valuable, as forming a natural barrier, in the loose blowing sand of many sea shores, to the encroachments of the ocean, being indeed one of the principal means by which the industrious Hollanders have gained a part of their territories from the sea. It is in England comprehended with *Arundo arenaria* and *Carex arenaria*, (see those articles,) under the name of Marram, and acts of parliament have been made for their preservation. The roots and leaves of such grasses being very durable, retain the blowing sand, of which they accumulate more and more as they extend in growth upward, and thus gradually form a natural and very firm bank. In a clay soil they are of no avail. Of the economy of the American or Siberian species of *Elymus*, we have no information. Two annual European species, *E. Caput-Meduse* and *E. Hystricæ*, are furnished with very long rough capillary awns, by which their seeds are not only wafted to a distance, but detained by the accumulation of blowing sand, when they have once alighted, till they can fix themselves by roots.

ELYOT, Sir THOMAS, in *Biography*, a gentleman eminent in various branches of learning, and a patron and friend of most of the learned men in the reign of Henry VIII., was descended of a good family in the county of Suffolk, and son of Sir Richard Elyot. He was educated at St. Mary's Hall, in Oxford, where he made a great progress in logic and philology; but the year in which he entered (like the year of his birth) is not certainly known; it is, however, supposed to have been about the year 1514. After he had spent some years at the university, he travelled into foreign countries, and, on his return, was introduced at court. His uncommon genius and extensive learning recommending him to the favour of Henry VIII., who was a great patron of men of letters, his majesty conferred upon him the honour of knighthood, and employed him in several embassies. He sent him, particularly, to Rome in the year 1532, on the subject of the divorce of

queen Catharine, and afterwards to the emperor Charles V. in the year 1536. Elyot was, as Wood observes (see his *Athen. Oxon.*) an excellent grammarian, poet, rhetorician, philosopher, physician, cosmographer, and historian; and was distinguished as much for his candour, and for the innocence and integrity of his life, as for his accomplishments. He was admired and beloved by all the men of learning who were his contemporaries, and his memory is celebrated by them in their respective works, particularly by Leland, in his "Encomia Eruditorum Virorum." He was buried on the 25th of March 1546, in the church of Carleton, in Cambridgeshire, of which county he had been sheriff; and a monument was soon after erected over his grave. He possessed several manors in Cambridgeshire, and one or more in Hampshire.

He wrote and translated several works. 1. "The Casket of Health," which is said to have been first published in 1541; but Dr. Aikin observes, that his edition of that year is asserted to be "corrected, and in some places augmented, by the first author thereof." It was reprinted in 1572, 1580, and 1595. The reading of the author, as it appears from his *proleme*, or preface, was unusually great, considering that he did not follow the profession of physic, having extended to the works of all the Greek, Arabian, and Roman writers of credit. This book was greatly esteemed, not only by the public in general, but by some of the faculty in his time, and is, indeed, fully as worthy of notice as most of the medical pieces of that age. His rules for diet and regimen, when not drawn from Galenical theory, are on the whole founded upon plain good sense; and he uniformly inculcates temperance of every kind. This he carries to a degree, with regard to certain enjoyments, that would no doubt be generally thought somewhat too rigorous, except by such a bridegroom as the old gentleman in La Fontaine, who would be pleased with our knight's authority to add all the months, from April to October, to the red letter days of his calendar.

We learn from the work in question, that the disease now called a *cold*, began to be common in England in the time of Elyot. "At this present time," he says, "in this realm of England, there is not any one more annoyance to the health of man's body, than distillations from the head, called rheums." The cause of their being so much more frequent than they used to be forty years before, he supposes to be "banquettings after supper, and drinking much, especially wine, a little after sleep;" and also covering up the head too hot, a practice which prevailed to such a degree, that he tells us, "now a days, if a boy of seven years of age, or a young man of twenty years, have not two caps on his head, he and his friends will think that he may not continue in health; and yet if the inner cap be not of velvet or satin, a serving man feareth to lose his credence."

The other works published by sir Thomas Elyot, were, 2. "The Governor," in three books, 1544, 8vo.; 3. "Of the Education of Children;" 4. "Banquet of Sapience;" 5. "Prefervative against the Fear of Death;" 6. "De rebus memorabilibus Angliæ;" 7. "An Apology for Good Women;" 8. "Bibliotheca Eliotæ, or Elyot's Library or Dictionary," 1541, folio; which work was afterwards augmented and improved by Cooper. He translated also from the Greek into English, "The Image of Governace, compiled of the Arts and Sciences, by the Emperor Alexander Severus," 1556, 8vo.; and from the Latin into English, "St. Cyprian's Sermons of the Mortality of Man," 1534, 8vo.; and, "The Rule of a Christian Life," written by Picus, earl of Mirandula, printed in the same year.

(Gen. Biog. Dict. Aikin's Biog. Memoirs of Med. in Great Britain.)

ELYRUS, in *Ancient Geography*, a town of the island of Crete, which, according to Pausanias, was situated in the mountains.

ELYS BAY, in *Geography*, a bay of the island of Antigua, on the N. coast, a little to the south of Beggar's Point.

ELYSII, in *Ancient Geography*, a people who inhabited the eastern part of Germany.

ELYSIUM, ΕΛΥΣΙΟΝ, in the *Ancient Theology*, or rather *Mythology*, a place in the inferi, i. e. in the lower world, or, as we sometimes render it, in hell; furnished with fields, meads, agreeable woods, groves, shades, rivers, &c. whether the souls of good people were supposed to go after this life.

Orpheus, Hercules, and Æneas, are supposed to have descended into elysium, in their life-time, and to have returned again. Virgil. lib. vi. ver. 638, &c. Tibullus, lib. i. eleg. 3. gives us fine descriptions of the-elysian fields.

Virgil opposes elysium to tartara; which was the place where the wicked underwent their punishment.

"Heic locus est, partes ubi se via findit in ambas:  
Dextera, quæ Ditis magni sub mœnia tendit:  
Hac iter elysium nobis: at læva malorum  
Exercet pœnas, et ad impia tartara mittit."

He assigns elysium to those who died for their country, to those of pure lives, to truly inspired poets, to the inventors of arts, and to all who have done good to mankind.

Some authors take the fable of elysium to have been borrowed from the Phœnicians; as imagining the name elysium formed from the Phœnician ἕλυ, *alaz*, or ἄλυ, *alats*, or ὄλυ, *alas*, to rejoice, or to be in joy; the letter a being only changed into e, as we find done in many other names; as in *Enakim*, for *Anakim*, &c. On which footing, elysian fields should signify the same thing as a place of pleasure; or,

"— Locos lætos, & amœna vireta  
Fortunatorum nemorum, sedesque beatas." Virg.

Others derive the word from the Greek λυω, *solvo*, I deliver, I let loose, or disengage, because here men's souls are freed, or disencumbered from the fetters of the body. Be-roaldus and Hornius, Hist. Philosoph. lib. iii. cap. 2. take the place to have derived its name from Eliza, one of the first persons who came into Greece after the deluge, and the author and father of the Ætolians. According to Diodorus Siculus (l. i. c. 36.) the whole fable of the infernal regions was borrowed from the funeral rites of the Egyptians, and introduced into Greece by Orpheus. Hence Homer is said to have borrowed his ideas and descriptions, which occur in various parts of the *Odyssey*. Accordingly in the fourth book he gives the following account of elysium in the address of Proteus to Menelaus:

"Elysium shall be thine; the blissful plains  
Of utmost earth, where Rhadamanthus reigns.  
Joys ever young, unmix'd with pain or fear,  
Fill the whole circle of th' eternal year:  
Stern winter smiles on that auspicious clime:  
The fields are florid with unfading prime:  
From the bleak pole no winds inclement blow,  
Mold the round hail, or flake the sleecy snow.  
But from the breezy deep, the best inhale,  
'The fragrant murmurs of the western gale."

Pope's Od. b. iv. v. 765, &c.

The other poets as well as the philosophers seem to have copied their notions of hell and of the elysian fields from Homer. Plato, in his account of the state of departed spirits, represents the soul of the deceased as passing into a place, which he calls divine, and as being there judged. If his life was conformable to the right of reason, he is advanced to a higher apartment, where he enjoys pleasure and prosperity in the society of the gods; whilst the souls of bad men sink into a noisome abyss, there to dwell in thick darkness, and to endure every kind of misery. Socrates also adopted similar ideas. This philosopher distinguished a three-fold state of souls departed. Those who had neither singular merit nor enormous vices, inhabited the confines of Acherusia, where, being purified by the waters of the lake, they received the rewards of the few virtues they had practised. The souls of the wicked wandered about their tombs, where they were tormented in different ways. After which, having drunk the water of Lethe, they entered into new bodies, more or less honourable, according to their merit. The souls of the good went immediately into the elysian fields. Pythagoras maintained, that the soul, upon its immediate separation from the body, was conducted by Mercury into a place of the purest air, in which were the elysian fields, called by Virgil the "aerial regions," *aerios campos*. The souls of the philosophers, which were the best of all, became like to the gods, while those of the wicked were tormented by the furies without intermission. Both the one and the other, after a certain period of purification, returned to the earth to animate new bodies. Thus did this philosopher inculcate, first in Europe, the doctrine of the metempsychosis, or transmigration of souls, which he is said to have borrowed from the Egyptians, and which had been taught before by Orpheus and Homer, who had borrowed it from the same people. Accordingly we learn from Herodotus, that the Egyptian priests maintained, that the soul does not die with the body, but is received into Amenthes, which was a place under ground, resembling the hell of the Greek poets. Plutarch says, that this word denotes "that which gives, and that which receives," and adds, that it was a place in the centre of the earth, the common receptacle of departed souls. Hence, after a certain period, they were released, and united to new bodies. The poets have delivered sentiments similar to those of the philosophers concerning the state of souls after death, and whilst each had his peculiar notions, all agreed, that the soul goes either to Elysium or Tartarus; though they are far from being unanimous as to the situation of these two mansions. Some place the elysian fields in the middle region of the air; some in the moon; others in the sun; and others again in the centre of the earth adjoining to Tartarus. The most common opinion is, that they lay in one of the isles of the ocean, called the "Fortunate islands," which are reckoned to be the Canaries. According to Ol. Rudbecks the elysian fields were situated in Sweden. In the opinion of many of the ancients, the mansion of the blessed was in the charming country of Betica (the present Andalusia in the extremity of Spain towards Cadiz,) whither the Phœnicians had travelled from the earliest times, and which was represented as a delicious country, possessing a fertile soil, abounding with enchanted groves, enriched by mines of gold and silver, and watered with rivers, streams, and fountains. According to Homer, the infernal regions were in the country of the Cimmerians, who are said to have inhabited the western coasts of Italy, near Baiæ and Puteoli, where Ulysses arrives on the same day that he takes his leave of Circe. Virgil has adopted Homer's notion, and places the mouth of hell upon the same coast, near the lake

Avernus. Others, however, of the poets, place the entrance of hell at the promontory of Tenarus, where was the cave from which Hercules dragged Cerberus when he went down to hell. Others seek for it in Thesprotia, and Lucan refers it to the banks of the Euphrates. The ancients differ in opinion with respect to the time, during which departed souls continued in the infernal regions. Some suppose that souls doomed to Tartarus continued there a thousand years, before the period of their transmigration commenced. Pindar fixed the residence of the blessed in the elysian fields for ever; whence, according to Virgil and the other poets, they were to depart after a certain period of time, having drunk the water of oblivion; and this period was usually limited to a thousand years. (See TARTARUS.) The poets, Homer, Virgil, Pindar, Claudian, Catullus, &c. describe the regions of bliss under a variety of pleasing images, such as green bowers, gliding streams, murmuring springs, charming meadows, serene air, perpetual springs, warbling birds, &c. Tibullus, whose imagination was voluptuous, represents it as abounding with mirth and all sensual pleasures. Virgil admits merely chaste and innocent enjoyments, and in this respect he has copied Homer.

ELYTROCELE, (from *ελτρος*, the *vagina*, and *κληνη*, a *tumour*;) in *Surgery*, a hernia in the yagina.

ELYTROID, in *Anatomy*, from *ελυτρον*, a *sheath*, and *ειδος*, *form*, is a name applied to one of the coverings of the testicle. See GENERATION, *Organs of*.

ELYTRON, properly a covering of any sort, and for any substance. Hippocrates has appropriated the word to signify the membranes which involve the spinal marrow.

ELZEVIRS, in *Biography*, celebrated printers at Amsterdam and Leyden, lay claim to a short notice in this work, on account of the many valuable books which were printed at their presses, and of the perfection to which they carried their art at a comparatively early period. The first of the family was Lewis, who was distinguished for his editions from the year 1595. He was succeeded by Bonaventure, Abraham, and Daniel, of whom the last died about the year 1680. The small types of these famous printers have a clearness and elegance which have rarely been equalled. Virgil, Terence, and the Greek Testament, printed in 1633, distinguished by characters in red ink, are reckoned master-pieces; and the best of their classics still maintain a high value. Moreri.

ELZT, or ELTZ, in *Geography*, a town of Germany, in the country of Lower Saxony, and bishopric of Hildesheim on the Saale; 9 miles S.W. of Hildesheim.

EM, or EMBAK, a river of Russia, in the government of Riga or Livonia, which issues from the lake Wyrzt, and falls into the Peipus.

EMANATION, formed of the Latin *e*, out of, and *manare*, to flow or stream, the act of flowing, or proceeding, from some source or origin. Such is the emanation of light from the sun; or that of effluvia from odorous, &c. bodies; of wisdom from God, &c.

The principle of emanation was adopted from the most remote times by the oriental philosophers, and by means of emanation from an eternal fountain of being, they endeavoured to explain the nature and origin of things. Zoroaster, at an early period, maintained this system, alleging, that various orders of spiritual beings, gods or demons, have proceeded from the deity, which are more or less perfect, as they are at a greater or less distance, in the course of emanation, from the eternal fountain of intelligence; among which, the human soul is a particle of divine light which will return to its source, and partake of its immortality; and matter is the last or most distant emanation from  
the

the first source of being, which, on account of its distance from the fountain of light, becomes opaque and inert, and whilst it remains in this state is the cause of evil: but, being gradually refined, it will at length return to the fountain whence it flowed. This doctrine of emanation afterwards produced many fanciful opinions in theology. It was adopted by the ancient Indians, and taught under various modifications by the Brachmans. The same system was likewise received among the Egyptians, taught by Orpheus and Pythagoras, and communicated to the Greeks either from Egypt or from the East. Wherever it originated, it was taught for many successive ages in the more civilized regions of Asia and Africa, and both before and after the commencement of the Christian era, it gradually spread through the Alexandrian, Jewish, and Christian schools. It was a distinguishing tenet of the Jewish Cabbala, of Simon Magus, and of the Gnostics and modern Platonists. This system, as it was taught by the oriental, Alexandrian, and Cabbalistic philosophers, comprehended the following tenets. All things are derived, by emanation, from one principle; which principle is God. From him a substantial power immediately proceeds, which is the image of God, and the source of all subsequent emanations. This second principle sends forth, by the energy of emanation, other natures, which are more or less perfect, according to their different degrees of distance, in the scale of emanation, from the first source of existence, and which constitute different worlds, or orders of being, all united to the eternal power from which they proceed. Matter is nothing more than the most remote effect of the emanative energy of the Deity. The material world receives its form from the immediate agency of powers far beneath the first source of being, and is the necessary effect of the imperfections of matter. Human souls are distant emanations from Deity; and, after they are liberated from their material vehicles, will return, through various stages of purification, to the fountain whence they first proceeded. Nothing can be more fanciful than the numerous fictions which are blended in this system, and which have been grafted upon it by enthusiasts of different descriptions, both philosophical and theological; inasmuch that it has been the soul of enthusiasm and fanaticism. (See THEOSOPHISTS.) Some of the modern Eclectic philosophers attempted to unite the atomic and emanative systems; and Jordano Bruno, in particular, founded his doctrine on the ancient system of emanation. See BRUNO.

EMANATION is also used for the thing that proceeds, as well as the act of proceeding. The power given a judge is an emanation from the regal power; the reasonable soul is an emanation from the divinity.

EMANATION is also used among the schoolmen, for the production of a lesser thing, in order to the production of a greater, by virtue of some natural connection, or dependence between them.

Hence that is called an emanative cause (in contradistinction to an efficient cause) which produces an effect by its mere presence, without the intervention of any action; as a rose doth a smell, &c. Others, and with good reason, deny that there is any such thing as an emanative cause, to produce an effect without any action. See CAUSE.

EMANCIPATION, formed from the Latin *ex*, of, and *mancipium*, a slave, in the Roman Law, was the act of setting a son free from the power and subjection of his father.

Emancipation differs from manumission, as the latter was the act of a master in favour of a slave, the former that of a father in favour of his son.

The effect of emancipation was, that the goods, and

moveable effects, which the son should thenceforth acquire, should be his sole property, and not the property of his father, as they were before emancipation. Besides, emancipation put the son in a capacity of managing his own affairs, and of marrying without his father's consent, though a minor, or pupil, and under twenty-five years of age.

There were two kinds of emancipation; the one *tacit*, which was by the son's being promoted to some dignity, or by his coming of age, or by marriage; in all which cases, the son became his own master of course.

The other *express*, where the father declared before the judge, that he emancipated his son. This was not performed without some formality: the father was first to sell his son imaginarily to another man, whom the lawyers call *pater fiduciarius*, father in trust; of whom being bought back again by the natural father, he manumitted, or set him free, by a declaration before the judge. This imaginary sale was called *mancipatio*; and the manumission consequent thereon, emancipation.

Emancipation obtained in France, chiefly with regard to minors, or pupils, who were hereby set at liberty to manage their effects, without the advice, or direction, of their fathers or tutors. It must be observed, however, that emancipation only extended to the selling of moveables, and letting of leases, &c. of immoveables; not to the selling or mortgaging of immoveables; which were only done with the consent of a curator, ordinarily a person appointed, when emancipated.

Formerly emancipation was performed in the ordinary courts of justice, when desired by the child; but if he were a minor, the king's letter was also required. Though there were other ways of emancipation, as by marriage; arriving at the age of twenty years; and in some provinces by the death of the mother, because the children were there under the power of the father and mother conjointly; so that the death of either of them emancipated the child.

Emancipation by marriage, in France, gave a power of marrying again, without the father's consent though under age; but among the Romans, Cujas tells us, a widow, under twenty-five years of age, though emancipated by her former marriage, returned into the power of the father, and might not marry a second time, without his consent.

Du-Cange observes, that the word emancipation was also used in the monasteries, in speaking of monks promoted to any dignity, or removed from under the power of their superiors; as also in speaking of monasteries, chapels, &c. themselves, when exempted by the pope, from the jurisdiction of the ordinary.

EMANUEL, in *Biography*, king of Portugal, son of the infant Don Ferdinand, duke of Visco, succeeded his cousin John II. in 1495. He was then in his twenty-sixth year, and highly esteemed for the excellent qualities of his mind. He began his reign by restoring the nobility to that consequence in the state of which it had been the policy of his predecessor to deprive them. He shewed an inclination to favour the Jews, who had been enslaved in the former reign; but by the violence of his advisers, he did not dare to follow the bent of his own mind, and demanded of these unhappy people, as the terms of their liberty, that they should instantly profess themselves Christians, in name, though a period of twenty years should be allowed them for their conversion. Most of them complied with the required condition; but others, and those not a few, voluntarily put an end to their lives, rather than submit to a dereliction of principle. Some of them were so indignant at the requisition that they first murdered their own children, and then

then committed the rash deed upon themselves; thinking death in any form better than an abandonment of the religion of their fathers. In 1496 he married Donna Isabella, daughter of Ferdinand and Isabella of Spain, who died the next year, having first given him a son and heir. This was the period in which the new passage to the Indies was discovered by Vasco de Gama, a circumstance which proved the source of great riches to Portugal, and contributed to fix the epithet of *fortunate* upon this prince. In 1499 he married the younger sister of his late wife; and in 1501, under his auspices, the Brazils were discovered, which have proved a more lasting benefit to Portugal than her Indian possessions, and which has at length become an asylum to the exiling monarch, driven by Bonaparte from his European possessions. Emanuel, in gratitude for the important discoveries made in his reign, founded the famous monastery of Bethlehem, near Lisbon. He now adopted the plan of making conquests in Africa, in which he was not very successful, but by the talents of Albuquerque he formed a very useful alliance with the king of Congo. Although prosperous in a high degree, he met with mortifications sufficient to lead him to declare his purpose of resigning his crown into the hands of his son. The eagerness which the young man shewed for power, and the marked attention which the courtiers paid him, caused the monarch to change his purpose. He died in 1521, in the 53d year of his age, at a time when he was regarded as one of the most powerful and splendid princes in Europe. Emanuel, when religion was out of the question, was capable of liberal and generous conduct. He treated with great favour Don George, natural son of the late king, for whom his father had endeavoured to procure the succession to the crown; and he restored to their titles and estates the Braganza family, who had suffered attainder and confiscation in the late reign. In the history of his country, Emanuel stands very high for piety, humanity, munificence, and those other good qualities that do honour to an enlightened sovereign. Univer. Hist.

EMANUEL-PHILIBERT, duke of Savoy, son of duke Charles III., was born in 1528, and though destined for the church, yet by the early death of two elder brothers, he was brought up as heir to the sovereignty. He visited the court of the emperor Charles V., by whom he was created knight of the Golden Fleece. He accompanied Philip II. into England, and was afterwards entrusted by him with the command of his armies. He was general at the siege of Metz, and at the battle of St. Quintin, in 1557, in which the French sustained a signal defeat. He married Margaret, daughter of Francis I. of France, and by that alliance regained all the dominions which his father had lost. At the persuasion of some bigots he attempted the extirpation of the Vaudois, protestants of Savoy, but was defeated in his projects, and by the influence of the duchess, who was well disposed towards the reformation, he willingly allowed them the exercise of their religion. He died respected and beloved in 1580, after a reign of 27 years. Univer. Hist. Moreri.

EMARGINATUM FOLIUM, in *Botany*. (See LEAF.) The term applies only to the extremity or apex of a leaf, and expresses a notch in that part, apparently caused by a greater tightness or contraction in the nerve, than in the softer more dilatible parts adjacent, which are therefore extended beyond it. The petals of flowers, however, are very often emarginate in their original conformation, as in many species of Chickweed or Sandwort.

EMASCULATION, the act of taking from a male

those parts which are characteristic of his sex. See CASTRATION.

EMAUX *de P'Esu*, in *Heraldry*, the metals and colours of a shield, or scutcheon.

EMBA, or YEMBA, in *Geography*, a river of Russia, which takes its rise in the southernmost part of the Ural mountains, and constitutes the border between the Usimskoi government and the country of the Kirchitzzi, though the forts are much more to the west, namely, on the river Ural. The Emba takes up only one river of note, the Sagifs, has a strong current, but is at the same time very shallow. It is the most easterly of all the rivers that fall into the Caspian.

EMBABE', a village of Egypt, opposite to Boulac, near Cairo, upon the west bank of the Nile, famous for the excellent quality of its butter, and for a variety of lupins, which grow in its vicinity, and called embaben. These are sold ready dressed in the streets and markets, and they supply Lower Egypt. Their general appellation in the country is "termefs." The Christians of the East eat lupins as a stimulus for drinking brandy. Flour is made of them, which is used for cleaning the hands and softening the skin. The stalk, reduced to ashes, is preferred to other charcoal in the composition of gun-powder.

EMBALMING, the opening of a dead body, taking out the intestines, and filling their place with odoriferous and desiccative drugs and spices, to prevent its putrefying.

The word is formed from *balm*, which was a principal ingredient in the embalmings of the ancient Egyptians.

Dr. Grew, in his *Museum Regalis Societatis*, is of opinion, that the Egyptians boiled their bodies in a large cauldron, with a certain kind of liquid balsam. His reason is, that in the mummies preserved in the collection of the Royal Society, the balm has penetrated not only the fleshy and soft parts, but even the very bones; so that they are all as black as if they had been burnt.

The Peruvians had an effectual method of preserving the bodies of their incas, or kings, embalmed.

The mode of embalming dead bodies among the Egyptians was as follows: when a man died, his body was carried to the artificers, whose trade it was to make coffins; they took the measure of the body, and made a coffin for it, proportioned to its stature, the dead person's quality, and the price that people were willing to give. The upper part of the coffin represented the person who was to be shut up in it, whether man or woman. If it was a man of condition, this was distinguished by the figure which was represented on the cover of the coffin; there were generally added paintings and embellishments, suitable to the quality of the person. Vide Cassian Collat. 15. cap. 3. & Cicero, Tusc. Quæst. lib. i. Herodot. lib. ii. cap. 86. Diodor. lib. ii. cap. 5.

When the body was brought home again, they agreed with the embalmers at what rate particularly they would have it embalmed, for the prices were different; the highest was a talent of silver, estimated at about 25*l.* 6*s.* 8*d.* or, as others say, about 300*l.*: twenty minæ was a moderate one, and the lowest price was a very small sum. They immediately sent for a designer, who marked the body, as it lay extended, at the place where it should be opened, on the left side, and the length of the incision. A dissector, with a very sharp Ethiopian stone, made the incision, and hurried away as fast as he could, because the relations of the person deceased, who were present, took up stones, and pursued him as a wicked wretch, with an intention to stone him.

This operation being finished, the embalmers, who were looked upon as sacred persons, entered to perform their office.

## EMBALMING.

office. They drew all the brains of the dead person through his nostrils, with a hooked piece of iron, provided particularly for this purpose, and filled the skull with astringent drugs; they likewise drew all the bowels, except the heart and kidneys, through the aperture which they had made in the side. The intestines were washed in wine from the palm-tree, and in other strong and binding drugs. The whole body was anointed with oil of cedar, after having been filled with myrrh, cinnamon, and other spices, for about thirty days, so that it was preserved entire, not only without putrefaction, but had a good scent with it. *Αιγυπτίοι δε τα νεκρά εξελόντες ταμιχέουσιν αὐτούς.* And the Persians, as the same author, Sextus Empiricus, observes, were used *νεκρῶ ταμιχέουσιν.* Sext. Empir. Pyrrhon. Hypoth. lib. ii. cap. 24.

Bodies thus preserved are called *mummies*, from the Arabic word *mam*, which signifies wax, this being an ingredient in the preparation.

After this the body was put into salt for about forty days; wherefore when Moses says, that forty days were employed in embalming Jacob, we are to understand him as meaning the forty days of his continuing in the salt of nitre, without including the thirty days past in performing the other ceremonies above-mentioned, so that, in the whole, they mourned seventy days in Egypt, as Moses likewise observes.

Afterwards the body was taken out of the salt, washed, wrapt up in linen swaddling-bands, dipped in myrrh, and rubbed with a certain gum, which the Egyptians used instead of glue. Then the body was restored to the relations, who put it in a coffin, and kept it in their houses, or in tombs made particularly for this purpose. There are some found, at this day, in Egypt, in chambers, or subterraneous vaults, which fully justify the truth of what is here said.

They who were not rich enough to bear this expence, contented themselves with infusing, by a syringe, through the fundament, a certain liquor extracted from the cedar, and leaving it there, wrapt up the body in salt of nitre. This oil preyed upon the intestines, so that when they took it out, the intestines came along with it dried, and not in the least putrefied. The body being inclosed in nitre, grew dry, and nothing remained besides the skin glued upon the bones. They who were too poor to be at any considerable expence, did no more than cleanse the inside, by syringing a liquor into it; this done, they put the body, without farther ceremony, into nitre for seventy days, in order to dry it. Calmet, Diction. Bibl. Pococke's Description of the East, vol. i. p. 230, &c.

The present method of embalming in Egypt differs very much from the ancient. Mallet informs us, that it is now the custom to wash the body several times in rose-water; then to perfume it with incense, aloes, and other odours, in great abundance; the body is afterwards wrapped up in a winding-sheet, made partly of silk, and partly of cotton, moistened probably with some liquid perfume; this is again covered with another cloth of unmixed cotton, to which is added one of the richest suits of clothes of the deceased. Letter X. p. 88.

The art of embalming, says Sonnini, is now unknown to the Egyptians. As soon as a person is dead, they press the different parts of the body, in order to make it discharge all its impurities; they repeatedly wash it, shave it, pluck out all the hair, and stop all the apertures closely with cotton; they then pour upon them odoriferous waters, and the perfumes of Arabia penetrate into all their pores. The in-

animate remains are then committed to the earth; and upon the spot where the head of the deceased lies, they erect a small stone pillar, crowned with a turban. Every Friday they resort to the foot of this sepulchral monument, and renew their mournful adieus.

Dr. Ward, in his Dissertations on this subject, supposes that the Jewish method of embalming was very different from the Egyptian, and that this appears from several passages in the New Testament. Both, as he conceives, swathed up their dead; but instead of the Egyptian *embowelling*, he supposes the Jews contented themselves with an *external unctio*; and that instead of myrrh and cassia, they used myrrh and aloes. To this account he also adds the supposition, that St. John might mention the circumstance of our Lord's embalming, in order the better to obviate the false report which then prevailed among the Jews, that the body of our Lord had been stolen away in the night by his disciples; for the linen, he supposes, could not have been taken from the body and head, in the manner in which it was found in the sepulchre, on account of its clinging so fast from the viscous nature of these drugs, if they had been so foolish as to attempt it. It is certain that the modern Egyptian mode of embalming, if it may be so called, differs very much from the ancient; but it is not easy to determine how far the Jewish method, in the time of our Lord, differed from that of the Egyptians. It does not appear indeed to be certain, that the Jews were not accustomed to embowel their dead in embalming. As all other nations seem to have embalmed exactly according to the Egyptian manner, the same causes that induced them to do so, probably occasioned the Jews not to vary from them in this respect. It does not, however, follow from hence, that our Lord was embowelled, though St. John says (ch. xix. 40.), that he was buried with spices, "as the manner of the Jews was to bury;" for these words do not necessarily signify, that all was done that was wont to be done in those cases among the Jews. Indeed, the contrary appears to have been the fact, from the farther preparations made by the women, who probably were not acquainted with what had been done, though Dr. Ward supposes the contrary; since St. Luke expressly tells us (ch. xxiii. 55.), that "the women, which came with him from Galilee, followed after, and beheld the sepulchre, and how his body was laid." Admitting this statement, Ward's thought concerning the difficulty of taking off the bandages, besmeared with very glutinous drugs, must appear to be unfounded; for in that case, the women could have done nothing more as to the embalming of him. Besides, aloes and myrrh do not appear to possess that very glutinous quality which Dr. Ward ascribes to them; and it is more reasonable to suppose that St. John mentions this circumstance, concerning which the other evangelists are silent, because he published his history for the use of persons less acquainted with the customs of the East, than those for whose information the others wrote. This reason induced him to say to those who were wont to *burn* their dead, that our Lord was *buried with spices*, which was in general the Jewish method of disposing of their dead; and this he might very well do, though the shortness of the time occasioned some deviation from what they commonly practised. This shortness of time prevented them also from swathing him with that accuracy and length of bandage, which they would otherwise have used; in conformity to the custom observed among the Egyptians, and probably also among the Jews: for we are informed, that the Egyptians have used above a thousand ells of filletting about a body, besides  
what

what was wrapped about the head. Such, indeed, was the hurry of the disciples, that our Lord's head was simply bound about with a napkin; a practice used by the Mahometans at this time. What was done by Joseph and Nicodemus with the mixture of myrrh and aloes, which they provided, doth not appear. Dr. Lardner supposes, they might have formed a bed of spices. A modern Jew, cited by bishop Kidder, objects to the history of the New Testament; alleging that the quantity was sufficient for 200 dead bodies, that is, allowing half-a-pound for each body. But this quantity falls far short of that which modern surgeons use in embalming. It appears from what Josephus (Antiq. lib. 15.) says of the funeral of Aristobulus, the last of the high priests of the family of the Maccabees, that the larger the quantity of spices used in their interments, the greater honour was thought to be done to the dead; and therefore we may easily account for the quantity brought by Nicodemus, though we may not be able to tell precisely how he disposed of it. Might not large quantities of precious perfumes be strewed, or designed to be strewed, about the body of our Lord? Harmer's Obs. vol. ii.

It is no wonder that we find human bodies preserved without corrupting for many ages, by means of spices, and other ingredients, proper to resist putrefaction, applied with the nicest care; but it is strange that there should be a sort of embalming performed by nature, in some places, where bodies are preserved merely by the virtues of the soil in which they lie; yet this is evidently the case in some instances. We have, in the Philosophical Transactions, an account of a man and a woman who were lost in the great fnows on the moors of Hope, near the woodlands in Derbyshire, on the 14th of January, 1674. These persons were not found till the 3d of the May following, at which time they smelt so strong, that the coroner prudently ordered them to be buried on the spot. These bodies lay buried in the peat-moss 28 years before they were looked at again; when some people of the country, who had heard of the strange virtues of the soil thereabouts in preserving dead bodies, opened the ground, and found them no way altered, the colour of the skin being fair and natural, and the flesh as soft as that of persons newly dead. Phil. Trans. N<sup>o</sup> 434, p. 415.

After this the place was remarked where they lay, and they were shewn for a sight for 20 years, though they were much changed by having been so often uncovered in that time.

**EMBANKMENT**, in *Rural Economy*, a large body, mound, or bank of earth, constructed and thrown up in different ways, according to circumstances, with the view of guarding, protecting, and defending lands on the borders of the sea, rivers, and lakes, from being inundated and injured by them.

They are of different kinds and forms, according to the nature of the situations and the materials of which they are constituted. In embanking against the sea and large rivers, where the slopes next them are naturally gentle and easy, they are mostly of the earthy description, being well put together, and covered on the surface with turf cut from the tough sward of the land in the neighbourhood; but, in cases where the banks, borders, and shores, are more steep and bold, they are usually of a more hard and solid nature: being often made with stone, brick, gravel, sand, shells, and other similar substances, laid closely in some sort of tenacious material, such as clay, mortar, and other matters of the same quality. Wood is likewise, in some instances, employed in their construction.

Vol. XIII.

In works of this sort, very much depends upon the form in which they are constructed, and the nature and management of the materials which are made use of in the business. In respect to the first, it may be remarked, that banks of these kinds are commonly constructed with too narrow bases for the heights which are given them: from which circumstance, the sides which are opposed to the effects of the water become too steep and upright; consequently, in cases of high tides or floods, they are utterly incapable of resisting their weight, which has equally a lateral and downright pressure. Besides this, there is another disadvantage attending this method of forming them, which is, that the floods, as well as the tides, in ebbing and flowing, have a more continued action on one part than would be the case, if the slopes were more gentle and gradual; consequently, they have a much greater tendency to break down and destroy the superficial parts of the banks. With some variations in the forms, most of the embankments in this country are, however, made in this way. They may succeed in some particular instances; but in general it is found, that breaches are frequently taking place in them, from the effects of the sea or floods, which are not capable of being filled up or repaired, without considerable difficulty and trouble; and which, if suffered to continue even for a short space of time, endanger the whole embankment.

The common form of embankment is shewn at *fig. 1, Plate X. Agriculture*, and the improved form pointed out at *fig. 2*, in the same plate.

The angles or slopes of these sorts of works are made very different in different cases; but that shewn in the above figure seems in general well calculated for the purpose of resisting the impression of heavy tides, or the waters of floods. The greater breadth they have in proportion to their height, the more effectual they must be in resisting the power of the waters which come upon them.

In regulating the heights of embankments, it is necessary to ascertain the greatest depth of water at the highest tides or floods; making the summits of them about two feet higher than the points to which they rise at such times. By some, a less height than this above the highest mark of the tides or floods has, however, been considered sufficient; but it is always proper to be on the safe side, as the consequences of an overflow are very serious.

In forming embankments with stones, or other similar materials, which, as has been seen, is essential in bold steep banks or shores, it is necessary that they be laid in proper materials, and be closely jointed next the sea, or the rivers, so as to be fully capable of resisting the entrance of water; as, unless this be the case, they will by no means be complete: for the water, insinuating itself between the openings, sinks down among the stones, softens and loosens the clayey or earthy matters underneath, by which portions of them are continually forced out and washed away; hollows being formed in that way below, and the stones naturally sinking down; in consequence of which, the waters rush into the cavities with considerable impetuosity, and quickly displace others, and the whole embankment is soon destroyed. This very frequently takes place with the heads thrown across rivers, and such paved or causewayed banks as are formed with the view of protecting and preserving those bold and open shores, which are liable to be undermined and carried away by the washing operation of the waters which come against them. In order to render the embankments perfectly secure in such cases, they should be laid with good mortar, and be pointed with a strong cement. A good coat of gravel, in some cases of this kind, is even found far superior to paving with stones.

E

In

## EMBANKMENT.

In constructing embankments of the quay, or other similar kinds, a mortar formed from powdered unburnt lime-stone and coarse sharp sand is employed; the whole being pointed with puzzolana earth, by which they become as solid as rock, and fully resist the effects of water. The lime of particular sorts of lime-stone is found more proper for forming this sort of mortar cements than that of others: thus, that found at Dorking in Surrey is supposed to constitute the most durable substance of this kind of any in the kingdom; and has been employed in forming the new docks in the river, near London. And an excellent sort of lime-stone for the same purpose has likewise been discovered near Worsley, in Lancashire, which is there termed Sutton lime.

It has been suggested by a late writer, that an excellent mortar cement for this use, which hardens under water, may be composed by having four parts of blue clay, six of the black oxyd of manganese, and nine of carbonate of lime, submitted to a white heat, and then well incorporated with sixty parts of sand, and as much water as may be necessary to form it into a mortar.

It is invariably found, in examining the shores of the sea, and the banks of rivers, that such as have easy and gently declining slopes from their beds to their borders or banks; and those which are formed in a steep upright manner, of rocky materials, such as are shewn at *figs. 3, and 4,* are the least exposed to injury from the effects of their waters: the two former being the most secure, when spread over or coated with good coverings of sand or gravel, or uniformly turfed over quite down to the water-side with the sward of a tough old pasture. The strength and firmness of their banks are in proportion to the extent of the slope; and their durability depends on that of their being made uniform on their surfaces, both in respect to hardness and smoothness: as, in the former case, from the great length of slope, the flows and decreases of the waters act more momentarily on their different parts, and their greater weight renders their banks more firm; while, in the latter case, by the equality of their surfaces, the power of the waters is rendered the same on one part as another, and no obstacles are left for the producing of eddies, or other means of forming holes or breaks in them.

In the latter, or those of the bold, upright, rocky kind of banks, their strength chiefly depends on the resistance of the large quantity of materials by which they are backed, and not on the manner in which they are disposed, as in the former case; and their durability, on that of the uniform compactness of texture in the parts opposed to the effects of the waters: as, where these have fissures in them, or are softer in some parts than others, the waters are liable to enter and break down the banks in time, according to the particular nature of the cases. A striking example of this kind lately occurred in the Isle of Wight.

It is, therefore, of importance that the modes and forms of embankment, which are thus naturally presented, should be improved upon by art. It is evident, that if a cut was formed behind the embankment, as in *fig. 5,* at the letter *x,* the shores or banks, though, in this case, as it were, detached from the land, would be found equally strong and capable of resisting the pressure of the waters, as in their original state. Hence, if a mound or bank was formed, and placed out at the distance of one, two, or three miles from the shore or other embankment, within the bed of the sea or other waters, as at *y* in the same figure, it would be equally capable of resisting them as in the former instance, and not more liable to be broken down by their pressure than in its former station; and would also defend

them as completely from the intermediate space of land, as it did before from the narrow trench. Consequently, on this principle, vast tracts of land may, in different parts of the kingdom, be obtained by judicious embankments.

Though the shores of bold steep coasts may not afford examples equally capable of being followed with advantage as the above, they nevertheless suggest useful hints for the purpose of defence, in cases of bold, abrupt, broken shores, constituted of earth, or of that material and rocky substances intermixed. It readily presents itself to the mind, that the raising a good perpendicular stone-wall against such banks, renders them nearly as strong and lasting as those formed by nature of steep, solid, rocky bodies. This sort of walled bank is exhibited at *fig. 6.* But though this method may be practised, in cases of the above kind, with great advantage, it is not by any means applicable in general to rivers; as, with them, the water, during the periods of floods, stands in need of room to spread, which is the great use of giving their banks a sloping form; while, in this way, by being confined, it would have the effect of doing more injury than was the case before. Instances may, however, happen in which it may be had recourse to with propriety, in defending a part of the bank of a river, without giving it a sloping direction, or for protecting one part of a bank at the risk of that which is opposite to it; but well-constructed piers, in such cases, are frequently more perfect, and constantly attended with less expence. But instead of these, art may suggest one that may answer in some respects more perfectly; as in place of bringing together such a mass of earthy or other substances, as may be proper for constructing such banks as are shewn at *figs. 1,* and *7,* it may be more advantageous to have one formed, such as is shewn at *fig. 8,* the side of which next the water forms with the base an angle of about 45 degrees. This will be capable of bearing all the weight or pressure of water that can possibly be brought upon it, equally well with that of *fig. 1,* except that the operation of the tides would break the superficial part of the side next the sea, unless prevented by coating it with some durable substance, such as paving stones, bricks, or other similar materials.

But various different ones may be invented between this and the first natural kind, which differ only in the degree of inclination which they have towards the sea; that which slopes in the highest degree, as *fig. 1,* having the surface covered over with sand or gravel; and that which has the least slope, as *fig. 8,* may be covered with pavement; the different intermediate slopes being protected by materials which have a quality between the two, such as coarse gravel, chalk-stones, brick, and sand, as shewn in *fig. 9.* This embankment is wholly constructed of a sandy loam, being deposited upon a soil of the same quality; but as it would not, for some time after being formed, be sufficiently impervious to water, a column of clay is carried upright in the middle, from the clayey substratum of the soil underneath, as shewn at *xx* in the section.

In cases where the shores are of a very sandy nature, it is frequently necessary to form the embankments wholly of a sort of wicker-work. In such circumstances, three or four rows of paling may be put down, of different heights; and the vacant spaces between them be well filled, by forcing in furze, brush-wood, or even straw, as represented at *fig. 10.* These substances, by detaining the mud and sand, as the tide passes through them, or during high floods, soon form a sort of embankment, such as that shewn in the above representation. It should afterwards be covered with some plant, which is capable of binding and giving it solidity, such as the *elymus arenarius.* This embankment would

continue,

## EMBANKMENT.

continue, during extraordinary tides, to retain still larger quantities of the sandy materials, until ultimately raised higher than they could reach, by which a safe bank would be formed. It is suggested by Mr. Loudon, in his useful "Treatise on forming Country Residences," from which many of the above hints have been drawn, that from twenty to thirty thousand acres of land might be gained in this way, in a very few years, in different parts of the rivers Severn, Humber, Frith, &c.

In all cases of embankment, however they may be formed, tunnels and sluices of a proper kind, with valves towards the sea or rivers, must be occasionally placed, according to circumstances, so as to permit the water that may be collected within to pass away, and that of the sea or rivers to flow up, with different intentions in the view of improving the land.

The utility of projecting points is very considerable, in different cases, on the sea-coasts and rivers, in defending the bays and inlets of the former, as well as guarding the banks of the latter, by diverting their streams or currents to the opposite sides. Hence arises the formation of piers, which become highly beneficial in defending embankments, as well as the borders of rivers and brooks. In the first of these cases, they may generally be constituted and coated over with the same sort of material as that of which the embankment is formed; while, in the latter, they should be formed of some sort of stony matter, being constructed in such a way as to decrease in every direction as they advance outwards, as represented in *fig. 11*. In each of these cases, they are, however, capable of being constituted of brush-wood, secured by means of stakes, often with more perfect success. And it frequently happens that a simple rude wicker-work fence, of not more than three or four yards in length, may be fully sufficient for the purpose. Embankments formed of stone, unless constructed in the manner represented at the above figure, are apt to cause eddies below them; while those formed of brush-wood cannot have this effect.

It is obvious that considerable attention must be required in deciding the most proper situations for constructing these sorts of projections in, and the distances to which they should extend into the rivers: as a too extended projection may be highly dangerous to the opposite bank, and of course do harm instead of being beneficial; while not carrying them out sufficiently may prevent the effect which is wanted. In cases where piers are to be formed of stone, as in rivers where the bottoms are of a rocky nature, the plan represented at *fig. 11* is probably the most proper, as it will scarcely cause any eddy, and be nearly equally mild with that of wicker-work in the effect which it produces. Different works of these several kinds have been constructed in the northern parts of the island with much success.

*Proper Materials for Embankments.*—There cannot be any doubt, but that different sorts of materials may be made use of in different situations and kinds of works of this nature, with more advantage than others, both in so far as duration and expence are concerned.

Those steep upright embankments which are constructed with the view of protecting bold shores, or coasts, and the banks of particular rivers, may probably be best formed of good brick, rubble, or ashler work in the manner of a wall, as seen at *fig. 6* in the plate, the materials being laid in the strongest sort of mortar that can be made. But where this is not the case, they may be built in the common way, and pointed with puzzolana earth, or what is termed the Roman cement, prepared by Messrs. Parker and Co. London.

The different kinds of sloped embankments may be formed

either with common earthy materials, clay, mud, or a mixture of these several different substances; and any other matters which are capable of uniting into a solid, firm, compact mass, may be had recourse to for the same purpose. Where the sides next the sea or other waters form angles of from twenty to thirty or even thirty-five degrees, with their bases, they may be coated with sand, the shells from the sea, or coarse gravel from the borders of the shores. And stones, broken down to uniform sizes of a few pounds in weight, may be employed in a similar manner. But where none of these substances are capable of being procured in sufficient abundance, a method practised in Holland, of covering them with such perishable materials as mats, reeds, straw, bark, and others of the same nature, may be had recourse to; but these are obviously disadvantageous, as requiring very frequent renewal. They might likewise be protected by a low fence of brush-wood, fixed in an erect manner all along at the bottom of the bank, of an equal height, as tending to break off the violence of the waves. Another method might also be employed, which is, that of covering the whole front of the bank with brush-wood, either made into bundles or in the manner of wicker-work, or fixed down in a neat manner by means of long poles and strong hooked stakes. And further, they may be laid in the form of caufeway with stones in moss, or covered with wicker-work applied upon the mossy material when spread out over the bank. And there are still many other modes which may be adopted under particular circumstances.

In all cases where the sides and slopes towards the sea constitute angles of from thirty-five to forty-five degrees, with their bases, as in *fig. 8*, recourse may be had to stones of the flag kind as coverings, which should be jointed with cement mortars formed in some of the manners mentioned above. And where these sorts of stones cannot be provided, if clay can be found, proper kinds of bricks may be made, and used in the same way as the stones. But where the slopes or inclined planes are from forty to forty-five degrees, it is frequently more cheap and economical to have them covered with stones of about six or eight pounds in weight, applied to the thickness of a foot and a half or nearly two feet; or these may be used on a bed of common moss of three inches, or of peat-moss of the flow kind, of six inches in thickness, spread upon the banks, only to the thickness of six or eight inches. Stones of these kinds may likewise be formed into a sort of caufeway, or be laid in strong clay, and their surfaces be jointed with lime or a strong cement mortar, which has the property of quickly hardening, and of enduring the operation of the air and tides, which alternately act upon it.

There may likewise be cases in which it may be the most advantageous practice to have the sides next the sea or rivers protected by coverings of wood only, in which cases, larch may be the most proper, or such others as are durable, having their surfaces covered over with pitch and some sort of sharp sand. And old sail cloth, or oil cloth pitched and coated over with sand in the same manner; or even thin plates of metals have been suggested as useful in particular instances.

*Expence of forming Embankments.*—This must obviously be very different in different situations and circumstances, according to materials and the price of labour, but though in general pretty considerable, it is seldom so high as is commonly supposed. It is probable that in cheap districts, and where the materials are plentiful, the expence of forming an earth bank covered with sand or gravel, such as that shewn at *fig. 1*, could not be less than from four-pence or six-pence, to ten-pence or a shilling the cubic yard. And such as have more steep and bold slopes, as from thirty-five to forty-de-

## EMBANKMENT.

grees, and are formed with pavement on the surfaces, cannot cost less than from nine-pence to one shilling and six-pence the cubic yard. One made on the plan of that shewn at *fig. 6.* could not be constructed for less than from twelve or fifteen to thirty pounds for every thirty-two yards. And one constituted of brush-wood, in the same method, for soft ground which will not admit of a wall, would not be lower than from six-pence or eight-pence to six or seven shillings for each foot forward in a lineal manner. In many situations the expences would, however, in all sorts of embankments, stand a great deal higher than these.

In some districts embankments are formed by the rod and the floor, the former being from four to five pounds, and the latter about four shillings and six-pence, the workmen finding all sorts of necessary things for the business.

*Extent of Land capable of being gained by Embankments.*—It is evident, that great quantities of land might in many situations be obtained from the sea and large rivers by the forming of proper embankments. Some notion of this may indeed be formed by a careful examination of such lands, as lie along their shores and banks, by ascertaining the distances to which the waters ebb out at common tides, as it is found by experience, that one half of the extent of land, thus uncovered in any particular situation, may at least be gained; hence throughout the whole kingdom it could hardly be estimated at a less quantity than from two to three millions of acres, but it is probably much more than even the last quantity, if it were capable of being ascertained with any degree of accuracy or correctness.

*Importance of Embankments.*—When the extent and value of the lands which are capable of being gained by these means are fully considered, there can be no doubt of their being of the greatest consequence to the interests of the country. It has been well remarked by a late writer on this subject, that there are numerous places in the kingdom where vast improvements may be effected by the judicious application of these means. Vast tracts of land of the best kind may not only be gained from the sea, but likewise from the large rivers and lakes, besides the beneficial consequences which must necessarily arise from the prevention of such rivers from overflowing their banks, and injuring the level grounds in their vicinity by such inundations. In some cases, it is supposed, that by raising a bank of only three or four feet in height, at very small expence, some thousands of acres might be prevented from being overflowed, the crops from being carried away, and much other mischief from being produced. In other instances the forming of very trifling banks might be the means of obtaining much extent of country, which in its present state is of but very little value; yet so indifferent are people in general about improvements of this description, that though immense tracts are year after year overflowed, and the most dreadful devastations committed, they have recourse to no means of prevention; nay, even though the sea itself, says the writer, as if to rouse them from their inaction, presents to their view twice every four and twenty hours large tracts that might by proper means be made of very great value, yet these repeated invitations are disregarded, and no attempts are made to possess what might, in many cases, be so easily and so advantageously acquired. This is considered altogether as extraordinary and unaccountable, while the acquisition of distant possessions is conceived by them of such great importance, as there can be no doubt but that the addition of portions of ground at home, when brought into proper cultivation, is of far greater national advantage than double the quantities gained in other distant countries.

The acquisition of additional territory at home should,

therefore, be more attended to, and have more expence bestowed upon it than has hitherto been the case. In particular situations, indeed, a few active and enterprising persons have taken advantage of the opportunities which have been presented; as in the counties of York, Lincoln, Cambridge, and others, many hundred thousands of acres have been gained by embankments. In Norfolk, too, a considerable extent of land has been gained in this way. In the neighbourhood of Chester, the river Dee company have likewise gained several thousands of acres from the sea, which have been since divided into different beautiful farms, the whole of which pay in rent more than two thousand pounds per annum. And in Holland the whole country has, in a great degree, been obtained by these means.

It is stated by Mr. Beatson, in the second volume of Communications to the Board of Agriculture, that large sums have been expended in some places by individuals, with a view of guarding against inundations; but owing to the embankments they have made being injudiciously placed, and as badly constructed, the desired effect has not always been produced, particularly in the northern parts of Cheshire, on the banks of the river Mersey, where works of this kind have been thrown up at a great expence, which, from the manner of their being placed, may, in some cases, by confining the course of the river, do more harm than good. By the appearance of that part of the country, so far as he could judge from the cursory view he had of it, it seemed to him that the inundations from that river might have been effectually prevented at a much easier rate, if a proper method had been taken at first; but from a certain ill-judged and mistaken tenaciousness of property, the embankments are reared so close upon the sides of the river, that, in many places, it is confined to a space not more than twenty yards over. Owing to this, and to an aqueduct across the river, with only one arch instead of two, which it ought at least to have had, the water sometimes, in great floods, rises, he was informed, to the height of about twenty feet above its ordinary level, and overflows the embankments, although now, by frequent additions, they are about that height. Instead of twenty yards, had these embankments been eighty or a hundred yards distant from each other, and the river widened in the narrowest places, one-third or one-fourth of their present height would have been quite sufficient. They would have been much easier constructed, and less liable to damage by the floods, and a great deal of money would have been saved, not only in the first construction, but in keeping the banks afterwards in repair. Neither would that space of ground between the embankments and the river be altogether useless; on the contrary, it would have produced the richest pasture, or meadow-hay, by its frequent manurings with the fertilizing particles left upon it, when flooded by the swelling of the river; and in those places, if any, that are unfit for pasture or hay, willows or other aquatics might have been planted to great advantage; and thus it might have been of more value perhaps than at present, and the interior grounds more effectually secured from the ravages occasioned by a sudden flood. Notwithstanding the general indolence shewn in most parts of the country respecting the acquisition of land by embanking, and the seeming aversion that most people have to engage in such undertakings, there have been, however, some ingenious and enterprising projectors, whose ideas upon that subject have soared far beyond the bounds allotted to common understandings. From the speculations of such people, the most important advantages are sometimes produced; and surely the man who is possessed of a speculative turn of mind, and who considers no obstacles insurmountable, is a much

## EMBANKMENT.

more useful member of society than he who is perpetually starting difficulties against every new project, and is for all things remaining *in statu quo*, that is, for leaving the world as he found it. The idea of embanking Lancaster sands, for example, never would have occurred to a torpid genius of this kind. A thousand difficulties and impossibilities would have immediately started up at such a proposal, which, to a more expanded mind, appear perfectly practicable to overcome. What then, says he, must those anti-projectors think, when they are told it is proposed to exclude the sea entirely from these extensive sands, which form a bay, exposed to a south-westerly wind, more than ten miles across, containing a surface of near forty thousand acres, and where the tide rises about fourteen to eighteen feet perpendicular height. Some proposals and estimates have already been made for carrying this project into execution. One very public-spirited and enterprising gentleman; the late Mr. John Wilkinson, offered to begin a subscription for that purpose, by leading off with the princely sum of 50,000*l.*; but so many unexpected obstacles have come in the way, by the claims of lords of the manors, and in proportioning the tithes, in the event of acquiring so large a tract of country, that few people have on that account chose to embark their fortunes in this immense undertaking, seeing that their profits may be liable to so many deductions; consequently nothing conclusive has yet been done in it. Ulverstone and Duddon sands, on the same coast, have also been proposed to be embanked. The latter, over which the writer went with major Gilpin, a gentleman who has paid great attention to that business, appears to be the most practicable. According to his opinion, there might be about nine hundred acres of very good land gained there, by laying out a sum not much exceeding 20,000*l.* If, on a correct survey being made by persons properly skilled in such undertakings, so valuable an acquisition is proved to be attainable at so small an expence, can there be the least hesitation about immediately commencing a project so highly advantageous to that part of the country, and to every individual concerned in it.

That there are many large tracts of land in different parts of the kingdom, both on the sea-coasts and on the sides of lakes and rivers, much more easily attainable than Lancaster sands, or any of the sands here noticed, there cannot be the smallest doubt. It is, therefore, an object worthy of the attention of those who are so fortunate as to possess property in such situations, to have it ascertained by persons of experience in such matters, how far the acquisition of additional portions of land may be adequate to the expence which it may be necessary to incur in procuring it.

But embankments are important in other views than those of gaining ground by them. When rivers are concerned, one material advantage is the deepening of their courses, by which vessels of greater burthen than they admitted formerly may be permitted to trade in them.

And further, as embankments become more frequent on the borders of rivers and sea shores, the intervening distances may become a sort of bays, in which accumulations of shells, mud, sand, gravel, and other matters, may take place by the influx of the tides; and these, however difficult they may be at first to epibank, will in time be as easy to perform the work on, as the natural bays and creeks are at this period. In this way many rivers, which in their present state are eight or ten miles in width at their junction or influx with the sea, may in the course of years be reduced to less than half these distances. Consequently such embankments would be equally beneficial to the proprietors of land, and the merchant or manufacturer, as many rivers would

become more easily navigable, and those obstacles which interrupt their mouths be wholly removed.

*Embanking against the Sea.*—When encroachments of this nature are to be guarded against by embankments, the methods of ascertaining their proper heights have been shewn above. But as new works of this sort, especially where the banks are large, are liable to subside too much, it may be a proper precaution to take the levels frequently for some time after they are completed, in order to guard against any mischief which might arise in this way. Where the banks are low this is not, however, so necessary, as the settling is always more or less according to their height; in low banks it will of course be very little. In the making of such embankments, it is scarcely possible to lay down any general rule in regard to their size or dimensions, as these must be directed by situation and circumstances, under the management of an expert engineer. In cases where the embankment to be formed is to exclude the sea from a piece of low marshy ground, over which it only flows at spring tides, the work is easy and capable of being accomplished at no great expence. But where it is intended to reclaim a portion of land which is covered every tide, in some bay or creek, or on the sides or windings of some large river in which the tide ebbs and flows, the business will be in some degree more difficult, according to the depth and rapidity of the current of the water. And where it is proposed to exclude the sea from some exposed situation at the mouth of a river, or in a bay or inlet, which is uncovered every tide, the operation will be the most difficult and expensive of all, according as it is exposed to prevalent winds, and the depth of the water to be resisted. Each of these situations, therefore, requires a different method of management. The business of embanking against the sea, when at any considerable distance within high-water mark, is not only the most tedious, but at the same time the most difficult of any; as when the materials are not very good and the work not well performed, the force of the water at every flowing of the tide will quickly undo all that has been effected, especially if the soil be of a sandy nature, as is often the case in such situations. If it be a strong clay, as is sometimes the case in marshy places, there will be the less risk of its being washed away. In sandy situations it has been advised by some to lay bundles of straw or reeds well fastened down, or any other impediment, to hinder the soil from being carried away by the ebbing tide. Where a sufficient supply of good strong turf cannot be had, expedients may be tried: but where such turf can be provided, as is the case in most marshy situations, and where the embankment required is not to exceed the height of four or five feet, it is best to finish the slope with good turf as expeditiously as possible, as the work proceeds; that is, supposing the length of thirty, forty, or fifty feet or yards of it can be completed in a tide; it is better to finish that length to its intended height, than to trace out or begin a greater extent than can be finished before the tide returns, by which a great deal of the soil might be carried away, and much of the work be demolished, which is not so likely to be the case when the slope is finished. Turf which contains the roots of bent or rushes is very good for this use. The first thing, however, to be done in an embankment of this kind, is to strike out the intended line of it, setting out the breadth at the base, also the width of the excavation or trench to be made in the inside, from which most of the materials that compose the bank are to be taken: this trench also serves as a drain to keep the grounds within dry. There should also be trunks or sluices at different parts of it, to shut of themselves against any external water, and to open when the tide ebbs,

## EMBANKMENT.

ebbs, to let out any water from within. The width of it should be proportioned to the quantity of materials required from it for the raising of the embankment, as eight, ten, or fifteen feet wide, and three or four feet deep, leaving a *berme*, or space, between the edge of the trench and the inner bottom of the embankment. If the soil be strong, one foot or eighteen inches will be sufficient for this purpose; but if loose or sandy, three or four feet at least will be required. The more easy and gradual the external slope is made, and the less sudden the resistance against the sea will be, as has been seen above, and of course the embankment be less liable to injury; this slope should therefore be formed according to the exposure of it to the winds and tides; nothing, however, can be a greater error than the making it too bold or upright. *Fig. 1.* in the plate, is supposed to be a section of an embankment of this nature, in which the base or horizontal line *g b* should at least be three times the perpendicular height *b i*, but *l m*, the inside slope, need not be more than three-fourths of the perpendicular height, that is, nine inches for every foot of rise. The inside slope should be faced with turf likewise, laid greenside downwards, as in building common sod walls. Some expert foddens can finish this sort of work extremely neat by setting the sod on edge, according to the slope intended to be given, and with proper mallets and beetles ramming the earth hard behind, which consolidates the work as it advances, and tends to render it durable. As soon as the first or lower course is finished, the upper edge of the fods is pared with a sharp knife quite even, by laying a rule to them, and then they go on with the second course, which they finish in the same manner, and thus proceed until the whole height is completed, which, when properly finished, has a smooth beautiful appearance, not a joint between the turfs being seen. Where turf is used in covering the outside slope, it should all be laid with the grass uppermost, as already noticed, and be well beaten down with a flat sod-beetle for the purpose, and in order the better to secure them, it may be proper to drive small stakes, about eighteen inches in length, through every sod. In cutting fods for this use, they should be taken up in a careful manner, and be all traced by a line of the same breadth; their edges being cut as even as possible, that they may make the closer joints, which will tend very much to their security, until they are grown properly together. In laying the different courses of such fods, care should also be taken that the joints of the one be covered by the other, in the manner that good brick work is made.

Where it is proposed to reclaim a piece of land, upon which the sea ebbs and flows every tide, to a greater depth than in the foregoing case, as in a creek, or on the side of a large river, a different mode of proceeding must be pursued, according to the soil, and the nature of the materials to be employed. Where plenty of stones can be readily procured, a bank may be formed of them, with a mixture of clay, either by means of land carriage, or which, in some instances, is better, by conveying them in flat bottomed boats, or punts, and throwing them over-board until the bank is formed. Where stones cannot be easily had, clay, or other materials proper for the business, may be thrown in, in sufficient quantity, in the same manner, with perhaps nearly equal success. It is supposed that most of the embankments in Holland were formed in this way, the clay dug from the canals being made use of for the purpose. In either case it is requisite to fix up strong poles before the work is begun, as guides for laying down the materials. Proper sluices must likewise be laid in suitable directions for taking off the back water when the tide ebbs, under the inspection of the engineer. Much, in all cases of this sort,

depends on a skilful engineer, who is capable of suggesting and contriving various means of facilitating the business, and of obviating the difficulties that may arise in its execution. A person of real genius is often capable, by his different contrivances, of rendering the accomplishment of a great undertaking comparatively easy, which to others would be almost impracticable, or carried on at such a heavy expence as to counterbalance the advantages to be drawn from it. In cases of the kind just noticed, he might suggest the erection of stages or platforms, in such a manner as to carry on the work at all times of the tide, which would be an immense saving, as the delays caused by the tides in this sort of business are both tedious and expensive. Waggon might likewise be contrived in such a way as to carry on such platforms large quantities of materials at once, which could be easily emptied and filled; and at the same time be drawn by machinery, in such a manner as to save much labour and expence, both in carriage and tide-work.

There is another species of sea-embankment which is, perhaps, the most important of any; as there are few estuaries or mouths of rivers in which large tracts of land may not be gained by it. The shoals, or flats formed at the entrance of such rivers, are mostly composed of the richest materials and most fertilising particles, brought down from the towns and circumjacent country through which they pass. Such shoals and flats may, therefore, under proper management, be in most cases readily converted into the most fertile plains. In such situations the first object is that of collecting the whole river into one stream, and preventing its overspreading a wider extent than is merely sufficient for its discharge, or it may be better, perhaps, to alter its course altogether, and cause it to be discharged at some other outlet. It is in this latter method that it has been proposed to reclaim the extensive tract covered by the tides, known by the names of the Lancaster and Milthrop sands, as well as those of Ulverston and Duddon. And the principle on which it is founded is this: it has been found by experience that where the course of a river is changed in such a manner as to make it discharge itself into the sea at a different place to that where it did before, the former place will, in a few years, by the continued accumulation of sand and mud brought in every tide, be so choaked up and raised above its former level, as to form of itself, in the course of time, a bank that, with a very little assistance, will quite exclude the sea; for as the current of the river before carried away all that sediment which the motion of the waves naturally stirred up, from its being now removed, it is obvious that all or most of the muddiness will not only be carried further up the old channel of the river, but a great part of it be deposited there as the tide recedes. It has been found that in spring-tides and particular winds, this sediment is deposited in larger quantities than at other times, and the writer has been informed that a gentleman in Lancashire, who has gained some land in this way, has found, on making a perpendicular cut in the ground so recovered, that the different layers were so distinct, he could readily distinguish those made at spring-tides from the rest. This curious fact is well deserving of the attention of all those who have lands situated at the mouths of rivers, as there may in many such situations be considerable tracts gained in this manner at a very light expence. But though this fact may exist in some places, as has been proved by experience, nevertheless it is supposed that the effect cannot be the same in all situations. Where there is a great extent of flat or muddy shores, the motion of the waves will no doubt stir up the mud or sand, and carry great quantities of them along with the current on the flowing of the tide, and when the tide ebbs, though  
some

## EMBANKMENT.

Some of the lighter particles will be carried away again, yet it is reasonable to suppose the heavier ones will be left behind. If the shores are bold and rocky, except just near the entrance of the river, there will be the less of this mud; but on such shores there can, indeed, be little or no occasion for embanking, unless perhaps in some creeks, narrow at the entrance and spreading out wide above. If the sea were excluded from such creeks, a great deal of land might probably be gained.

It was found, on having a survey made of the Lancaster sands, and of the proposed alteration of the course of the river Kent, that the length of the cut, necessary to be made from a little below Dalham Tower to the river Lune, was 21,340 yards, or twelve miles and one furlong. This cut was proposed to be about thirty-four yards wide, and four yards of average depth, making in the whole an excavation of 2,902,240 cubic yards: the expence of excavating which, at  $4\frac{1}{2}d.$  per yard, would amount to  $54,417l.$  But perhaps this estimate is rather under-rated at  $4\frac{1}{2}d.$  the cubic yard; but on the contrary the average depth of the excavation is presumed to be considerably over-rated at four yards, as a great part of the depth necessary may be made up by the soil thrown out; consequently whatever is made up cannot be considered as a part of the excavation; besides if the river Kent, Lindale pool, and the other streams proposed to be taken into this new cut, require, when united, a space or channel to contain them whose transverse section is 136 yards superficial, it would be much less expensive, it is supposed, to add eleven yards to the breadth; and to take one from the depth proposed, unless it be necessary, from the level of the bottom of the river, to make the bottom of the new cut of a certain stated depth. The whole expence of completing this great undertaking has been estimated at only 150,000*l.*, and in the opinion of some persons fifty, or perhaps sixty thousand less might be sufficient. It is, however, apprehended, that in this estimate there has been no allowance made for the necessary buildings on so extensive a tract, or for inclosing and draining; all which, as well as the interest of money laid out before any return can be expected, should be considered in calculating the expence of bringing into improvement such lands as these. And further, there are other estimates to be made for necessary buildings in its cultivation; besides in the estimates which have been made, it is taken for granted, that if the fresh water be conducted another way, as proposed, in a few years the sea will completely exclude itself from this extensive tract of land, and consequently no allowance whatever is made for any sort of embankment across those sands. Experience has not, however, so sufficiently shewn the certainty of this method of gaining land from the sea, as to place that sort of confidence in it that is requisite. If, indeed, it could be fully depended on, the speculation would be admirable, as well as the advantage and profits arising from such an acquisition immense; but if after laying out nearly perhaps 200,000*l.* in altering the course of the rivers, &c. it should be found that the sea left little or nothing behind, or if it did leave some at one time, but carried it all away at another, in what predicament must those persons concerned find themselves? They must either lose the whole of the money laid out, or they must expend at least 200,000*l.* more, perhaps, in performing what they had so implicitly trusted to the operation of the sea. If, however, it were certain that even a fiftieth part of an inch was deposited every tide, the success of the undertaking would be unquestionable, and a concern in it highly profitable, as in very little more than eight years ten feet of perpendicular height would be raised, and it would be an easy task to accomplish the rest of the business.

The Duddon sands are another tract, it is supposed, where great improvement is capable of being effected at a very easy rate, when compared with that just noticed. In the present state a great deal of land, that is capable of producing the best crops, is often overflowed and rendered so wet and marshy as to be of little or no value. While, by altering the course of that river, and bringing it farther north on the low marshy ground, it would seem from viewing it, without actually taking the levels, that not only the whole of the ground might be completely drained, but a considerable tract of lands be reclaimed. The making of the new channel for the river seems perfectly easy and practicable, the ground being nearly level, with the exception of a small rise at one place, all the way from where the new cut would begin, which is about two hundred yards above Duddon bridge to Havering pool; where it would empty itself into the sea. The length of this cut would therefore be about six miles, which ought to be made navigable all the way, with a lock near the sea, and a basin with proper landing places for delivering goods. The quantity of land that might be thus gained, including the sands and marshy ground on each side, would, it is supposed, on the authority of major Gilpin, be about 2000 acres, and the whole expence under 20,000*l.* The land, too, has every appearance of becoming one of the most fertile kind: in proof of which a farmer, who some years ago gained a few acres of it by embanking them against the sea, found that it produced the best crops of all kinds, even with little or no manure. So large a tract of valuable land, capable of being gained at so very trifling an expence, is therefore an object highly worthy of attention, not only as a profitable concern, but on account of many other advantages that would arise from it. It is, therefore, surprising, that the proprietors in the vicinity or other enterprising individuals have not long ago taken the necessary steps to reclaim these sands. The execution of these projects would, it is conceived, be attended with the most beneficial effects to a very extensive tract of country, and be ultimately felt in some measure by the nation at large. There would not merely be an addition of territory larger than either of the islands of Guernsey or Jersey, but it would tend to improve at least four times that extent of the interior country. A safe and speedy communication would be opened between the towns of Lancaster, Whitehaven, Ulverston, Ravenglass, Dalton, Bootle, Egremont, &c. and all the intermediate country, instead of a mountainous and very circuitous route, or a precarious and dangerous passage over Lancaster sands, in crossing which accidents are not unfrequent. Independently of the advantage arising from the produce of the lands to be acquired, the produce of the interior part of the country, which in many places is extremely fertile and well cultivated, would be easily brought to market; whereas it is at present, with the utmost difficulty and inconvenience, that any commodity whatever can be transported over these dangerous sands and almost inaccessible mountains. By diverting the river Duddon into the navigable cut proposed, it would yield the most important advantages to the town of Broughton and all the back country, by facilitating the importation of coal, lime, and other produce of every kind, and the exportation of slate, iron, and other productions of the country. But though different public-spirited individuals have been active in forwarding these highly laudable and important undertakings, the opposition which has been given by the proprietors of some trifling fisheries, who were offered a full indemnification, and from some lords of manors, who would neither contribute towards such improvements, nor relinquish any part of their claims to the ground when improved, they

## EMBANKMENT.

they have been for some time in a great measure in a dormant state. It is hoped, however, that in these enlightened times, when the spirit for improvements of this kind should be particularly aroused, these important and necessary projects may be again taken up in a serious and effectual manner, and that every obstacle which may stand in the way of their completion may be speedily removed. And that if the attempt of re-claiming Lancaster lands should be considered as a too expensive and too mighty undertaking to begin with, an experiment may be made on Duddon sands, where the money proposed to be expended is comparatively trifling, and where, if the scheme should succeed, there could not be the smallest reason for doubting the success of the other.

In the marshland district of the county of Norfolk, lying between the rivers Wyn and Ouze, immense tracts of the most rich land, such as is composed of the muddy depositions left by the tides and floods, which is there called *silt*, have been obtained by means of embanking. In this important business, the late count Bentinck, and his son, the present possessor, have been largely concerned. This kind of work has sometimes been undertaken by the tenants on a new piece of marsh, in consideration of having the land free for twenty-one years. But in these cases the banks have often been very imperfectly made, not having cost more than forty shillings a rod. And those which were constructed by the landlords were indeed frequently but little better, being mostly deficient in not having slope enough given them towards the water. Count Bentinck therefore laid his out upon a scale never practised in that part of the island before, and his successor has still far exceeded it. That planned by the former extends about four miles, and has added to the old estates not less than a thousand acres. The base of the embankment, in this case, is about fifty feet, the slope to the sea thirty-six feet, forming an angle, it is supposed, of about twenty-five or thirty degrees. The crown is four feet in width, and the slope to the fields seventeen feet, in an angle supposed of about fifty degrees; the slope towards the sea being very neatly turfed over. The first expence incurred in forming this bank was four pounds per rod, but a very high tide coming before it was finished, not only made several breaches, but occasioned an additional height and slope to be given to several different parts, in order to bring it to the dimensions mentioned above, all of which made the gross expence to amount to about five pounds the rod. The whole cost was something more than 5000*l.* The expence of the houses, farm buildings, and other things, was about as much more, for five new farms, which was a greater expence than was necessary, as the land would have let as well in two or three as five farms. Supposing, therefore, the expence at 10,000*l.* and the new rental as 1000*l.* a-year, it is just ten *per cent.* for the capital laid out. The expence here, however, seems to have run too high, when the necessary repairs of the bank are taken into the account. The representation, given at *fig. 11.* in the plate, fully explains the nature of the embankment formed in this case.

In another new embankment, in which two hundred and seventy-three acres of marsh land, and eighteen of bank were gained, the men were paid four shillings and six-pence a floor of four hundred cubical feet, finding wheeling planks, barrows, trussels, &c. When it is thus formed, the front slope is sodded, for which they are paid in addition four shillings a floor of four hundred square feet, earning from five shillings and six-pence to seven shillings a day, and there is some little further expence necessary for beating it down in a firm manner. The whole of the expence of the bank, sluice, and every thing else, was about 3300*l.* The

land was immediately offered to be rented at four pounds an acre for four years, or three pounds an acre for six years; which, in the former case, would amount to 4368*l.* in that length of time, or one thousand guineas more than the whole of the capital laid out in the undertaking.

On this coast the operation of *silt*ing up, or raising the surface of the marsh land by the repeated depositions of muddy matters from the sea, is performed in a more rapid manner than in many others; and the little hollows and creeks are found from experience to silt up much faster where the tide waters are speedily taken off by proper cuts and channels formed for the purpose, than where the contrary is the case.

*Embanking against Rivers.*—The embankments against rivers may be divided into two kinds; namely, such as are for preventing their encroaching on the adjacent lands, and for protecting those lands and the neighbouring level country from being overflowed, when the water rises above its ordinary level. It may be remarked, that where the course of a river is a straight line, or nearly so, it hardly ever makes any encroachment upon its banks, unless, perhaps, in very large rivers when they rise above their common level, either owing to an increase in the waters, or to their being, in some degree, affected by the tides. In either case, the waves occasioned by a strong wind, where the river is wide, will moulder away the banks on that side upon which it blows, unless prevented in proper time. This may be done either by securing the bank properly with stones, or by driving a row of long piles pretty close together at a little distance from the shore, the piles being of such a length, and so driven, that their tops may be always above the highest rise of the water. It is surprising the effect that piles driven in this manner have in resisting the power of the waves in such situations.

Some years ago, when Mr. Beatson was on duty as an engineer at a fort near Portsmouth, built on a point of land much exposed to the sea, the waves made such havoc, that the walls on that side were constantly giving way, although built in the most substantial manner, and having bulwarks of large heavy stone besides to protect the foundation: however, all would not do; those bulwarks were soon knocked to pieces, and several times the wall itself. At length it was proposed to drive a number of piles at about forty to fifty yards from the fort. These piles were twelve or fifteen inches in diameter, and driven about one diameter from each other nearly in a straight line, parallel to the wall where the waves did so much damage. They were driven into the ground with a pile engine till perfectly firm, perhaps eight or nine feet deep, and about two feet of the top of them left above the level of high-water mark. After this was done the wall received no farther injury, the space between the piles and the fort being always perfectly smooth, however tempestuous the waves might be without. The same simple method might, it is supposed, sometimes, perhaps, protect the banks of large rivers, if exposed to the waves, when other methods might fail.

But it is suggested, that the most common course of rivers encroaching on their banks, is the resistance occasioned by a sudden bend. In flat countries, apt sometimes to be overflowed, where there are any such bends or windings in the rivers, it would be of great advantage to straighten the course as much as possible, for, as every impediment or obstruction will naturally cause the water to rise higher than it otherwise would do, and as such bends have that effect, consequently, in the time of a flood the waters will overflow a greater extent of country, and to a greater depth than if the river had a free and uninterrupted course straight forward.

## EMBANKMENT.

If the windings of the river cannot be altered, and encroachments are making on some part of the banks, it must first be considered, whether the force of the water can be driven to another place where no injury can be done. If, for example, a river is encroaching on its banks, at  $x$ , *fig. 2.* a jutty of stone, a little way up the river in the direction  $yz$ , would throw off the current towards  $w$ , and might totally prevent any further encroachment. On the river Nith, in Dumfriesshire, it is stated that a good deal has been done in this way by Mr. Millar of Dalfwinton, a gentleman of the most enterprising genius and most liberal mind, who has paid more attention, and laid out more money in making important and useful experiments, than almost any other private individual. The course of the river, where Mr. Millar has been carrying on his operations, is said to be nearly as shewn at *fig. 3.* by  $rstu$ ; at  $t$ , it was encroaching most rapidly, and seemed inclined to take a new course towards  $v$ , which would have destroyed some very fine land, and done a great deal of mischief in that part of the country. To prevent this, Mr. Millar made a large cut about 400 yards in length from  $w$  to  $r$ , and threw in a great quantity of stones quite across the river at  $t$ , to direct its course in a straight line from  $r$  to  $w$ . This had, in a great measure, the desired effect, by totally preventing its progress at  $t$ , but now it began to encroach on its banks at  $u$ . He at first endeavoured to prevent this by driving in at a considerable expence a number of piles at a little distance from the bank, and wattled them with willow branches, &c. thinking thereby to protect the bank. The piles were drove in with heavy mallets, apparently firm into the ground; they continued so for some months, till a heavy fall of rain came on, which swelled the river, undermined the piles, and carried them all away. But, indeed, it is in vain to think of piles doing any good in such a situation, unless firmly driven in by a pile engine; for it is not possible to drive them in properly with mallets; this must have been the cause of their giving way so soon. The piles not succeeding, Mr. Millar was resolved to try another plan; several of his adjacent fields being covered with an immense quantity of stones, he ordered them to be gathered and thrown into the river, so as to form a jutty at  $x$ , a little way above the injured bank. Being obliged to go from home about that time, and to leave the execution of the work to some country people, they carried out this jutty too much at right angles to the stream. It had not, therefore, the desired effect, but rather made the matter worse than before; for, if a jutty is carried out at right angles, as at  $a$  in *fig. 4.* the current will be forced from  $a$  to the opposite side of the river at  $b$ , and from thence it will rebound towards  $c$ , more violently than it did before. But if a jutty be placed obliquely, as at  $d$ , it will force the current gradually towards  $e$ , in which position one jutty may do more good than several placed improperly at right angles. Mr. Millar was, therefore, under the necessity of making other jutties in this way, and has now the satisfaction to find that they answered the purpose intended. These he made laterally formed a sort of convex slope, the convexity being parallel to the current. Strong planks were also firmly set on edge among the stones, their ends pointing towards the river, so that if ever any current came so rapidly as to move any of the stones, it must move them all in a body the whole length of the plank. Perhaps this precaution was unnecessary; for although stones are thrown into a river loose in this manner, the slush sand, &c. that come down the river will soon fill up all the cavities, and render it as firm and solid as a regular built wall. Mr. Beatson has been the more particular in this description, he

says, in order to shew the errors that Mr. Millar at first fell into, and the great expence they occasioned, whereas, had he been on the spot himself, and got the work executed as he intended, it would have saved a great deal of unnecessary labour as well as money.

It is stated by the same writer, that the next sort of embankments against rivers, are those to prevent them overflowing their banks, and inundating large tracts of country. This may be considered as the simplest and easiest of all sorts of embanking, if judiciously executed. It is, therefore, the more inexcusable to see, in some places, extensive tracts of the richest meadows completely overflowed by every flood for want of them.

Two ordinary sized rivers rise no more even in the greatest flood than five or six feet above their common level, unless when they meet with some considerable interruption or confinement in their course. But if interrupted or confined, they will rise twenty feet or more, as is the case with some parts of the river Mersey already mentioned. If, for example, a given quantity of water is six feet deep, when running over a space twenty feet wide, it is clear, if that space was only made ten feet wide, the water would rise to twelve feet, and if it were made forty feet wide, the same quantity of water would only rise to the height of three feet.

It is, therefore, of great consequence, in preventing inundations, to give the river as much width as possible, by widening every narrow place. All kinds of obstructions should also be removed, whether occasioned by windings, shoals, stones, trees, bushes, or any thing else. In some cases this may even preclude the necessity of embanking; but where embanking is necessary, let the banks by all means be at a sufficient distance from each other, to contain with ease, between them, the largest contents of the river in great floods. The distance and height of the banks may easily be ascertained by measuring a section of the river when at its highest, or when the flood mark is visible. By not attending to this, a great deal of money has been thrown away on the embankments on the river Mersey, and after all they do not effectually answer the intended purpose; a great part of the country being still overflowed every time the river rises to any considerable height.

Where a sufficient distance is allowed between the embankments their height need not exceed from four to six feet. If irremovable obstacles are in the way, which cause the river to rise higher, the banks must be higher in proportion. In either case, however, the slope of these kinds of banks on each side may be equal to its perpendicular height, and the breadth on the top about one-third of that height, which, supposing the bank six feet high, the base would be fourteen feet, and the breadth of the top two feet, as shewn at *fig. 5.* in the plate.

The materials for making these banks should be taken as much as possible from the sides of the river, which will have the double effect of widening the river and forming the embankments; and there should be a trench on the inside (from which materials may also be got) with some sluices, as formerly directed, to drain off any water from within; also sluices to let in water from the river, if required, which would very much fertilize the meadows if properly laid out for that purpose.

Such farms as are situated on the borders of rivers are frequently, it was observed by a late writer, liable to much injury and inconvenience from them; 1st. From part of the soil being carried away in times of flood. 2d. From their overflowing their banks. 3d. From their flowing back in times of flood into the channels of the rivulets and streams that conduct the water from the more elevated and distant

## EMBANKMENT.

grounds to the rivers, whereby these rivulets and streams are made also to overflow their banks.

In respect to the first, the danger of the soil being carried away in time of floods, it is increased or decreased according to circumstances, as the form of the banks, the nature of the soil, the rapidity of the river, and the quantity of water that lodges on the margins of the banks, or falls over them into the river. Where the banks of a river are perpendicular, especially if the soil be of a rich mouldering nature, the danger of part of them being carried away by floods is much greater than where they slope gently from the surface of the field to the bed of the river, as has been already fully seen.

Where that is not the case naturally, they ought to be moulded into that form by art; as when a river, in place of being confined in its progress, has a power of efflux and reflux, the damage to be apprehended is inconsiderable, compared with what is likely to happen when, being restrained within too narrow limits, it is constantly struggling for an extension of space. Where the soil is rich free mould, and the under stratum opposite to the greatest force of the water, sand, or gravel, this struggle never fails to be attended with bad consequences. If the soil and subsoil be one entire mass of clay or strong loam, and the current of the river does not press more upon one part than another, a most substantial improvement may be effected by sloping the bank, so that the declivity may be one foot in three or four from the surface of the field to the bed of the river. This some may object to, as sacrificing a certain portion of valuable land; but it should rather, it is thought, be considered as a premium paid for the insurance of the remainder, than as a total loss. If gravel, mixed with small stones, can be conveniently procured, spreading these materials on the sloping bank to the depth of eight or ten inches, and till beyond the flowings of the river, will prove a good security against further damage; and if the bank be planted thick with any sort of willow, especially the Dutch willow, it will in a short time become an impenetrable fence, while the annual cuttings of wood will soon be equal to the heritable value of the land thus apparently sacrificed. Where no gravel can be procured, the new sloped bank should be immediately covered with well swarded turf, which should be pressed down as hard as possible, either with the back of a spade, or with wooden mallets. If this be done in the beginning of summer, and willows be planted the following autumn, the improvement, it is supposed, will be both effectual and permanent. In case the river run with extraordinary violence against any one particular part of the bank, it may be necessary to make a fence or bulwark of stone in the front of that place; the best way of doing which, is, in place of building a wall, to drop the stones in a careless manner, but so as they may lie close together on the sloped bank, as already suggested.

This is a much more secure mode of fencing, if the bank be made with sufficient declivity, than any stone wall that ever was built for the purpose, and while it is the most secure, it is also the least expensive; but care should be taken to lay the stones all the way from the bed of the river, till considerably beyond where the river flows in common. Where the soil is of a strong adhesive nature, and the under stratum is sand or a pebbly gravel, it becomes in a much greater degree necessary to slope the banks. The water, when rushing violently along, has a powerful effect in undermining the bank, and carrying off those incoherent substances; so that the soil, having nothing to support it, naturally gives way, and frequently in such quantities as to occasion very serious losses both to proprietors and tenants. In all such

cases, the slope should be made much more gradual than where the soil and subsoil is of the same quality, and such as will nourish aquatic plants. The banks, having been sloped according as circumstances require, a thick coat of gravel, mixed with small stones, where such can be procured, should be laid on so as to form a kind of natural beach, over which the river, when in flood, may have power to extend itself at pleasure. Should it be difficult or impossible to procure such materials as are proper for forming this best of all defences, strong thick sods should be placed on the surface in the manner before directed, which, if laid on in spring, or early in summer, will have time to unite, and to become one compact body before the autumnal floods (which are those whence the greatest dangers to be expected) begin to flow. If the subsoil be of such a nature as that willows will not grow, such sods as are full of the roots of rushes should be made choice of in preference to all others; as where these plants thrive and spread over the surface, it becomes in a great degree impenetrable by water, even in great floods, and when the river runs with considerable violence and rapidity.

The directions above given will, it is supposed, be found more or less practicable and useful according as the river on ordinary occasions runs with greater or less rapidity. In level, or nearly level districts, all that is necessary is to secure full scope for the rivers to overflow their usual bounds without interruption; when that is secured by either of the methods before mentioned, floods, unless very violent, seldom do any material damage to the banks of rivers in such situations. It becomes in many cases extremely difficult to fence rapid running rivers in such a manner as to prevent part of the banks from being carried away by inundation. Sloping the banks would be attended with no good consequences. Even strong bulwarks made of stone are often swept away by the overpowering flood. A method has, however, been suggested, of fencing the sides of a rapid running river, which has been practised with success, after several other attempts had failed; it is by means of a sort of large baskets, provincially termed creels, formed of hazle, willow, &c. into a kind of open net work, which being placed along the bottom of the banks, were filled with stones. This is a very simple, and by no means an expensive expedient; and as these baskets may be made to contain two or three tons of stone, it can only be on few occasions, and in very particular situations, that a basket, containing such a weight, can be displaced or carried away. Such a mode of fencing as this, it is imagined, would prove effectual in many parts of Scotland and Wales, where the rivers run with uncommon rapidity. Owing to inattention, or rather to not being aware of the consequences, much damage is often done to the banks of rivers in level districts, especially if the banks be perpendicular, and of a considerable height, by allowing the land floods to fall over them into the river. As the water from the furrows approaches the bank, it is frequently stopped in the furrow of the head ridge, which becomes for a time a kind of reservoir; the consequence of which is, that a considerable proportion of water sinks and filters through the earth, which being thus softened and swelled, is more easily undermined and carried off by the river. Sometimes little cuts or openings are made for the furrows across the head ridge, for the purpose of conducting the rain water into the river; here, again, the consequences are equally bad. Whoever will examine the bank of a river where this mode of management is adopted, and it is very common, will observe, that at every one of these cuts or openings a little creek is formed, in consequence of the bank having been more softened, and by that means hav-

ing

## EMBANKMENT.

ing become a more easy prey to the river when in flood. To prevent these evils, it is necessary, besides sloping the banks, to devote a part of the lands adjoining to the breadth of twenty or thirty yards, for instance, either to pasturage or the growth of trees, and to form a drain at a proper distance from, and parallel to the bank, for the purpose of collecting and carrying off the water from the furrows. Were this done, and were the water from this drain conducted into the river by conduits formed a little above its ordinary level; much land, which is annually lost by neglecting this simple precaution, would be saved, and preserved in a proper state.

In the second case it is evident that injuries, although of another nature, are often sustained by farmers, from rivers overflowing their banks. Sometimes the farmer is prevented from sowing his field; at other times the crops of grain and grafs are greatly injured, by being covered for a considerable time with water; and at others again, the whole produce of the year, the hay and corn crops are swept away. To prevent evils so complicated, and so serious in their nature, is certainly the business of every man, who, from the situation of his farm, has reason to apprehend, that without using proper precautions, he may be subjected to such visitations. These damages can only happen in level tracts, where the banks of the rivers are low, and where the course is not of sufficient breadth to contain the water in time of flood. Some people, although very improperly, raise mounds of earth close to the top of the bank, and of a height exceeding that to which the river can be expected at any time to rise. These mounds, from being placed so near the river, are unable to resist the pressure of the water, and by giving way, frequently admit a current into the fields, which proves much more injurious in its course than if no mound whatever had been erected. Were a mound of earth, formed on the side of the drain, proposed to be made for carrying off the land water, and were that mound well sloped on the side towards the river, it would be the most secure and effectual guard against rivers doing injury to the adjoining lands, of any that could be adopted. By these mounds being placed at a distance from the river, the force of the stream would be much lessened, and the natural boundaries of the rivers greatly enlarged, as in proportion as the mounds are removed from the centre of the current of the river, in like proportion will they become more secure, as being less liable to violent pressure. The propriety of erecting these mounds at a proper distance must, therefore, be sufficiently evident, as when mounds are erected near the top of the bank, which can only be owing to ill-judged parsimony, they form as it were a part of the bank, and are liable to be undermined and swept away. Whereas, when they are placed at the distance of twenty, thirty, or forty yards, they serve rather as a boundary to confine the overflowing waters which glides along the bottom, than as a barrier to prevent the encroachments of an impetuous river during the time of floods.

In regard to the third case it is observed, that farmers who possess lands in low situations often sustain damage from rivers, in time of flood, by their flowing back into the channels of the rivulets and streams that conduct the water from the more distant and elevated grounds to the rivers, whereby these rivulets and streams are made also to overflow their banks.

The only precaution that can be adopted, in such a case, or at least the one which appears to have the greatest probability of answering the purpose, is to erect mounds at a distance from the banks, and of a size proportioned to the quantity of water which, from the cause now men-

tioned, may be supposed at any time to stagnate in these channels. This may be done at a very trifling expence either in money or land. If the proprietors do not choose to ornament the county and improve their own estates, by planting trees on the borders of the rivulets and streams, the farmers may so construct these mounds, as that they may become fences to their arable fields, while that portion of the farm, necessarily and properly cut off for the protection of the remainder, may be devoted to pasturage.

Several different embankments of a successful kind have been lately effected in the northern parts of the kingdom. An important work of this nature has been executed on the estate of lord Galloway, situated on the mouth of the river Cree, near Cree town, by his lordship's tenant, Mr. Thomas Hannay, who states in the third volume of the "Farmer's Magazine," that he "entered to the farm about four years ago, on a lease of twenty-one years, and his life; at which time upwards of 100 Scottish statute acres were regularly flooded by the highest spring-tides, excepting about three months in summer, when the tides were lower. They were seldom, however, covered above the deepness of one or two feet, and never above four or five. Eighty acres of the above consisted of a rich sea marsh, or *ings*, as they call them there, almost a true level, excepting where hollows were formed by the egress and regress of the tides, and the passage of fresh water from the higher grounds; and about four or five acres, which were about sixteen inches lower, being a younger marsh, and nothing but what they call ink-grass growing upon it (as he is no botanist he can give it no other name); other grasses, such as clover, rib-grass, &c. grew on the rest of the marsh, forming a very beautiful close cover in the summer. The other twenty acres were at an average about eighteen inches higher; consequently, the sea did not cover them so often. It had formerly been ploughed, but not for about twenty years past. Last time it was in corn, it was flooded immediately after being sown, which rendered the crop almost entirely useless, and deterred former tenants from ploughing it again. He began to bank this field in the autumn of the year 1798, by making a dike along the side opposite to the river, in a direct line facing the east. This dike was made, at an average, about three feet and a half high, and six feet broad at bottom, and twenty inches at top, built after the same manner with that mentioned below. "He inclosed, along with the said fields," he says, "four acres of the marsh adjoining, by making a dike five feet high, and five feet in bottom almost wholly of solid seals or sods, with a very little stuff, properly beat, in the heart of it, which makes an excellent fence, and promises to be a very durable one. This dike, together with two small drains, one on each side of it, about two feet deep, cost 3*d.* per yard. He has been more particular in mentioning this dike here, he says, as the division dikes of the whole marsh, which is now divided into four parts, are all built after the same manner, only that there is no loose stuff in the heart of some of them, but all of solid seal, jointed like brick, as may be seen at *fig. 6*, which represents an end-view, or section of it. This dike, meant as a permanent fence, answered as a temporary bank, and enabled him to plough that field in spring 1799, although the bank round the whole marsh was not finished till the winter following." He "sowed oats on this field, and, considering the badness of the season, had a very good crop; particularly so on that part which had not been ploughed formerly. On further consideration, he altered the plan of the bank round the marsh, (which extends in a circular direction facing the north,) by making it, at an average, about four feet and a half high, and allowing about two feet in

## EMBANKMENT.

the base for one in height, as at *fig. 7*, where *abc* represent an end-view, or section of it, every small span representing the section of a seal or sod; *ab* shews the inside of the bank, with the green side of the seal down; *bc* the base; *ac* the side next the water, with the green side of the seal out, (which adds greatly both to the strength and beauty of the bank); and *d* the heart of the dike, made up with stuff properly compressed with a rammer. The stuff was taken from a ditch in the inside of the bank, leaving a casement of a foot, which ought to have been three at least; and, where the ground is of a sandy nature, more; as the fresh water, running in the inside, was likely to undermine the bank, had he not prevented it, by cutting a new drain, and filling the old one with the stuff cast from it. The only creek worth noticing, through which the bank passed, was one about forty feet wide, and nine feet deep, in the bottom of which a wooden pipe, with a stopper, was laid through the bank. No tide offered the smallest injury to the bank till January last, when there was one of the highest ever remembered by the oldest inhabitant, which broke it at this creek. This, he thinks, was owing to the wooden pipe not being made strong enough, as the weight of the stuff and water pressed in the sides of it, and thereby admitted the water below. The tide made also three small breaches in that part of the bank, which was built after the first manner; but in the part made after the manner represented in the figure, no breach took place, though it was rather lower than the other part. There are now about fifty acres of the same kind of marsh land adjoining his; and also about 100 acres on the other side of the river, banked in, all nearly in the same manner as represented in the figure. The bank on the farm adjoining his, suffered little from the high tide; but the one on the other side of the river was made almost a complete wreck, owing to its lying quite opposite to the south-west winds, which always send up the highest tides; but this is not the case on this side, these winds blowing right over their bank. In his opinion, the bank on the other side of the river, in order to be durable, would require to be thirty feet broad, and eight feet high, covered with seals, with the green side out; and that no stuff should be lifted within six or seven feet of it, the ground being of a sandy nature. It might be made after the form shewn at *fig. 8*. He has now got the breaches in his bank made up, and has begun to give the whole a complete repair, by adding, at an average, fifteen inches to its height, and two feet of base for each foot in height. The whole bank is about 1500 yards in length, and, when the repairs are completed, will altogether cost him betwixt 80 and 90*l*.

“In the year 1800, he ploughed another field, he says, of about twenty-six acres of the marsh, besides the one formerly mentioned, on which he had an excellent crop of oats, thought by many to be the best they had ever seen. Last year, he had the same field, part in oats, and part in wheat: the wheat was a very good crop; and the oats, which were of the Polish kind, far exceeded the crop of the former year. Last summer, he levelled the old ridges of the first-mentioned field, all by the spade; gave it a complete summer-fallow; shelled and dunged it well; had part sown with wheat, part with potatoe-oats, and all with grass-seeds. The other field is sown, part with wheat, and part with beans drilled; and, what is very surprising, he says, although the wheat was covered several times by the salt water, when the bank was broke, some of it to the depth of three feet, yet it is all looking well. The whole marsh is, he says, this year, under the plough. It may be worthy of observation, that the four or five acres, which

he mentioned as being a younger marsh, harrowed easier than the rest, and produced as good, if not better, crops.”

Another improvement of the same nature has been accomplished, on what in Scotland is termed Carse land, on the farm of Netherton of Grange, belonging to James Peterkin, esq. by Mr. John Hoyes, his tenant; the estate having been let to him on a nineteen years lease. The work was undertaken under an agreement with the proprietor, to allow one year's rent of 195*l*. sterling, with the further allowance of ameliorating the farm-houses to the extent of 150*l*. more. It is stated in the work already mentioned, that, “under these circumstances, the embankment was begun about the 1st of June, 1802; and, in November, it was brought to its full height over the whole; so that the Carse has been completely defended from the sea ever since the spring tides in October. He cannot positively ascertain, he says, the extent of ground gained, as it has not been measured since the dike was erected; but, from the last survey of that part of the estate, it would appear fifty acres were improveable; from which is to be deducted the quantity occupied by the base of the dike, the border on the outside, with a few detached spots, probably included in the measure.” The method adopted for carrying on the operations was this: “After looking over the Carse, and marking out the line or dike, the length of which is 1400 yards, mostly in a right line, except an angle at the distance of 300 yards from the west end, and a segment of a circle at about 250 from the south-east end, it was resolved to make the embankment six feet of height in the highest part of the ground, and to allow two feet of breadth in the bottom of every foot of height, as seen by the draught of the mould at *fig. 9*. After taking the level of the Carse, it was found, he says, that where the ground was low, and a good deal of it broken by runs of the sea and outlets for the water, the dike would require to be eight and ten feet high, to have it on a level at the top; so that the average will be nine feet high. The embankment was built in the following manner: It was begun on the highest ground, near the west end, and two moulds set up at the distance of seventy or eighty yards; the height six feet by twelve broad in the base; the slope on the outside six feet, on the inside four feet, and the breadth at the top two feet; the sides made up with seal from the broken ground on the outside of the dike, which were laid with the grass-side down, two feet deep on each side of the dike; the outside seal of the first course with the ends out and in, and the other running along; the next course, the outside seal running along, and the inside out and in, and so on alternately, each course consisting of a head and runner; the body of the dike being made up of the Carse ground from which the seal had been cut, and packed down by men with beaters. When this was brought to the height of four or five feet, another piece was begun, leaving an intermediate space, where there were any water-runs, for the egress of the tide: this was found necessary, to draw off the water from the low parts of the Carse, which would have been filled up in spring-tides; and, by coming in at the end and over the high ground, would have been prevented from getting out by the dike, if it had not been done in that way; so that the embankment was all in detached pieces, till it was brought near the height. These intermediate spaces were then filled up, betwixt the fall of one and rise of next spring-tide, after laying down wooden pipes with stoppers in the dike, to carry off the sink-water.” He adds, that “it was a great labour to get the work carried on; in some places having to cross over lakes and runs made by the tides, which required vast quantities of materials, the dike being

## EMBANKMENT.

in some places upwards of ten feet high; and twenty-two broad in the base: the greatest part of the dike is sixteen to eighteen feet broad. There was one lake, of 150 feet in length, and fifty feet in breadth, filled up with earth, clay, and sand, to the height of five feet; on which the dike was then built. This forms a mound, on the outside of the dike, of fifteen or sixteen feet broad; and through this there are pipes laid, to carry off the sink-water." He further adds, that "a stream of water formerly ran this way; but it was turned by the west end of the farm, by cutting a canal, which conveys the water through the embankment there, by means of an outlet built of stone, with a sluice on the inside, raised to the level of the running water, and a folding-door on the outside, to be shut by the spring-tides. At this place, a road, that formerly led to Findhorn at low water through the Carse, is carried over the top of the dike, by making a mound of earth at each side, with a gradual approach and descent." It is stated further, that "since the Carse has been enclosed, the tides have been so high, that the water, during a severe storm, was from six to seven feet deep at the back of the dike: the wind, being from the north, occasioned a heavy swell and surge, but no water came over the top of it." He suggests, that "it is in contemplation, as soon as the ensuing season permits, to cover the outside with seals, the green side uppermost; and he has no doubt, when finished, it will effectually secure the lands from any further visitation of the sea. The expences of the embankment cannot be well ascertained at present; but it will be a good deal more than is allowed by the proprietors." He says, that "a great part of the land is already ploughed; but, the winter setting in so severe, prevented the whole from being done. It is intended to fallow it, in preparation for a crop of oats in the succeeding spring; but this intention may not be unalterably adhered to. There are various sorts of soil in it: some of it clay, sand, gravel, black rich earth, and parts of it of a mossy nature; in some places below the gravel, which may, he thinks, have been forced on by the tides, a thin stratum of clay, upon sand; and some parts, clay and sand alternately. There are other parts not so rich as might be expected, the surface having been carried off by former tenants, for mixing in their dunghills or compost heaps. In *fig. 9, a* is the breadth of the dike at the top, when finished; *b*, the breadth of dike at bottom, being twelve feet, when it is six feet high; *c*, the breadth when eight feet high; *d*, the breadth when ten feet high; *f*, the slope on the sea-side of the dike, which is always equal to the half of the breadth of the bottom: the inside slope, and breadth of the dike at top, is equal to the other half; and *e* is a plumb-rule in a frame, made to apply to the mould or dike: the intention of it was, to find if the dike was kept on the proper slope, where a line could not be applied from one mould to another, as in a round or turn, or when the moulds were obliged to be taken down; but this one only answered for the sea-side, another being used for the inside, to fit its slope." *Fig. 10.* is a scale of the mould one-eighth of an inch to a foot.

Various other improvements of this nature have been accomplished, in particular circumstances and situations; and large tracts of land thereby rendered more than doubly beneficial to their occupiers. The methods which have been had recourse to, in such cases, will be fully detailed in speaking of *Hough-land and Rivers*.

A curious, useful, and highly ingenious method of embanking, and preventing the waters of the tides from soaking through the porous banks, formed in fenny and moorish

situations, has been described by Mr. John Smith, in the fourth volume of "Communications to the Board of Agriculture," who begins by "consistently observing, that the great land of the fens is divided into three large levels; and that each of these levels is subdivided into numerous districts by banks: but as these banks are made of fen moor, and other light materials, whenever the rivers are swelled with water, or any one district is deluged either by rain, a breach of banks, or any other cause, the waters speedily pass through these light, moory, porous banks, and drown all the circumjacent districts. The fens have sometimes sustained 20,000*l.* or 30,000*l.* damage by a breach of the banks; but these accidents seldom happen in the same district twice in twenty years; the water, however, soaks through all fen-banks every year, in every district; and when the water-mills have lifted the waters up out of the fens into the rivers in a windy day, a great part of the water soaks back through the porous banks, in the night, upon the same land again." And he adds, that "this water that soaks through the bank drowns the wheat in the winter, washes the manure into the dikes, destroys the best natural and artificial grasses, and prevents the fens from being sown till too late in the season. This stagnant water lying on the surface, causes also fen agues, &c. Thus, says he, the waters that have soaked through the porous fen-banks have done the fertile fens more real injury than all the other floods that have ever come upon them."

Having been much concerned in fen-banking from his youth, he had some time since devised the plan which he now finds to answer so well; but found it difficult to prevail with any gentleman, who had a proper extent of this sort of land, to give it a fair trial. However, during the last autumn, he prevailed with a person in the parish where he lives to try it, which shewed it to be equal to his highest expectations.

This improved method of embanking chiefly consists in this: that "a gutter is cut eighteen inches wide, through the old bank down to the clay, (the fen sub-stratum being generally clay,) the gutter is made near the centre, but a little on the land-side of the centre of the old bank. This gutter is afterwards filled up in a very solid manner with tempered clay; and to make the clay resist the water, a man in boots always treads the clay as the gutter is filled up. As the fen-moor lies on clay, the whole expence of this cheap, improved, and durable mode of water-proof banking costs in the fens only sixpence *per* yard. This plan was tried last autumn on a convenient farm, and a hundred acres of wheat were sown on the land. The wheat and grass lands on this farm are now all dry, whilst the fens around are covered with water. This practice answers so well on this farm, that all the farmers in this parish are, he says, improving their banks in the same manner, and some have begun in adjacent parishes."

It is unquestionably a mode of practice that requires to be fully known and understood, in all those districts which have lands of this description; as by it great advantages may probably be derived.

*Embanking against Lakes.*—The business of forming embankments, in cases of what are termed lakes, or mires, in this part of the country, and loughs in Scotland and Ireland, is much more simple and easy than in the preceding cases. It has been remarked by Mr. Beatson, that the waters in these situations generally subside during the summer months, rising considerably in winter, and whenever the season is very wet. In particular cases, the extent of surface, which is overflowed in the winter season, so far exceeds

exceeds that which it covers during the summer, that it would be an object, and sometimes a considerable acquisition, to confine the water within its summer boundaries, or to cut off some of its parts. Where these are intended, the principal outlet must be first carefully examined, and be considerably widened and enlarged; which, on the principle already noticed, in speaking of rivers, will prevent the water from rising so high as was formerly the case. Where the levels will not admit of much depth being had, or where the ground is of a rocky nature, and would of course be difficult and expensive to deepen, the breadth should be increased as much as possible, and all obstacles cleared away, that the water may run freely in a shallow stream. Where it is required to ascertain with exactness, or to fix with certainty, the future limits of the water, a section of the greatest quantity running out during a flood should be taken. Suppose this section, for example, be ten feet in width and four feet in depth; by making it forty feet in width, the same quantity of water will not rise above one foot: consequently, by this means alone, three feet in height will be gained all round the lake, which, in case of embanking it, would be a great object. During the summer season, when the water is lowest, is the most proper time for carrying on these, as well as other embankments. When, however, any materials are to be brought from a distance, they may be laid down or be prepared at other seasons, with the exception of turf, which should always be used as soon as possible after it is cut. The manner of constructing embankments of this kind may be sufficiently understood, from what has been already said in the other descriptions of embankments: observing, however, as a general rule, that when the materials on the spot will answer the purpose, they should invariably be made use of, although at the expence of digging a trench larger and deeper than would otherwise be necessary. It should constantly be attended to, in executing all sorts of embankments, that the greatest care be taken to make them perfectly firm and solid, by continually beating them, and examining them carefully, during the whole of the time they are in the state of being formed.

The various methods and plans of management, which are necessary to be adopted in the improvement of such lands as have been gained from the sea, will hereafter be more fully considered and explained. See *MARSH-Land*.

**EMBANKMENT**, in *Canal-making*, is a term for any large mound of earth, either for confining the water of a canal or reservoir, or upon which a canal or aqueduct is formed across a valley or low piece of ground. It may have arches under it, for the passage of a road, a river, or brook: such are called *aqueduct-arches*, and ought by all means to be constructed on the true curve of equilibration, for avoiding the great expence and disgrace which attends the failure of less scientific arches, as at Wolverton on the Grand Junction Canal. See *CANAL*.

**EMBAR**, in *Geography*, a town of Africa, in the country of Senegal.

**EMBARCADERO**, in *Commerce*, a Spanish term, much used along the coasts of America, particularly those on the side of the South sea.

It signifies a place which serves some other considerable city farther within land, for a port, or place of shipping, *i. e.* of embarking and disembarking commodities.

Thus Calao is the embarcadero of Lima, the capital of Peru; and Arica the embarcadero of Potosi. There are some embarcaderos forty, fifty, and even sixty leagues off the city which they serve in that capacity.

**EMBARGO**, a restraint or prohibition, laid by a sovereign on merchant-vessels, to prevent their going out of port; sometimes to prevent their coming in; and sometimes both, for a limited time. See *PROCLAMATION*.

Embargoes are usually in time of war; in apprehensions of invasions, &c. One great occasion of embargoes is, that the government may make use of the merchant-vessels, with their equipage, &c. in armaments, expeditions, transporting of soldiers, &c.; another is, to stop the communication of intelligence at such critical seasons. Embargoes are of very mischievous consequence to commerce.

**EMBARKATION** of *Ordnance and Stores*. The first thing necessary is to prepare a list of all the articles to be embarked, with the weight of each. This list must have an ample column for remarks; and the reputed tonnage must have an allowance of one-third added, for all articles whose weights and measures are not always the same, but receive, or lose, in consequence of damp, dirt, &c.; such as tents, &c.: but the tonnage of ordnance, shells, shot, &c. should be set down at their actual weight, according to their natures, calibres, &c. respectively. If vessels are paid for according to the tonnage they carry, the master will, of course, stow away to the best advantage, and load with as much as the vessel can possibly contain; whereas when freighted for a voyage, upon the estimated tonnage of the hold, they will stow so very loosely, as both to carry less, and to subject the cargo to considerable injury. It is, therefore, proper that a naval officer should be appointed to superintend every embarkation, and to see that every thing is stowed to the best advantage. It may be useful, in this place, to shew how tonnage is estimated. The usual method of finding the tonnage of any ship is,—Multiply the length of the keel by the length of the beam, and half that product by the breadth of the beam; divide the last product by 94, and the quotient will be the ship's tonnage. Thus, say a ship's keel measures 90 feet, and that her beam, *i. e.* her extreme breadth, be 30:

$$90 \times 30 = 2700 \times 15 = \frac{40500}{94} = 430.8 \text{ Tons.}$$

The tonnage of goods and stores is taken sometimes by weight, and sometimes by measurement; and that method is allowed to the vessel which yields the most tonnage: were it otherwise, the owners would be considerably losers in the freight of bulky, light articles, on which the calculation by weight would give them but little claim to charge; and, *vice versa*, if ordnance, shot, &c. were to be carried by measurement, they would be under a similar disadvantage. In tonnage by weight, 20 cwt. make a ton; and in tonnage by measurement, 40 cubic feet make a ton, the same as in timber computations. All carriages, or other stores to be measured for tonnage, should be reduced to their smallest dimensions, by taking to pieces, and packing into as little space as possible. All ordnance is shipped according to actual weight; as are also musket cartridges in boxes or barrels, and other such ponderous articles. The following table will exhibit the rates of tonnage allowed for the embarkation of the most material stores in the ordnance department.

## EMBARKATION.

When ordnance and stores are embarked, all appertaining to the same species should be classed and divided into the several vessels, in such manner as may insure the safe arrival of a certain portion; thereby avoiding that great inconvenience which could not fail to arise, were any one vessel, containing the whole of any particular stores, to be lost, taken, or unable to make the place of destination. With each piece of ordnance should be embarked every thing necessary for its service; so as to be instantly come at, when required to be landed. This principle should be carried to the fullest extent: even the platforms for the battering cannon should be in the same vessel with them; and, in short, every precaution ought to be taken to obviate delay, or omission, or imperfection. In general, all the heavy stores should be put in first; both to prevent their crushing less substantial articles, and to serve as ballast: the lighter stores, being generally most perishable, should be stowed uppermost, and be all numbered according to their several natures, and to their several intentions. Thus, every piece of ordnance, its carriage, and even all the parts of that carriage, together with its sponges, rammers, limbers, and boxes, ought to bear the same number; so that, when about to be landed, the whole may be discharged at one time from the ship, and be sent on shore in that regular manner, which may enable the artillery men and artificers to mount every one in succession with promptness and exactitude. All the chests, barrels, &c. must be lettered and numbered distinctly, in such manner as may indicate their respective contents. The numbers, &c. ought to be painted in clear white on a black ground, thereby to be legible at night: for the same purpose, it would perhaps be found useful to have the letters marked with white-headed tacks; so that, when not legible, for want of light, as often happens, they may be traced with the finger. In shipping gun-carriages, it is eligible to send them down into the hold, &c. without taking off the axle-trees from the cheeks; as they cannot be replaced without proper workmen, and a tedious operation. When a carriage is dismounted, all the small articles, such as elevating-screws, lynch-pins, drag-washers, &c. should be carefully collected, and secured either in a small box, or in a bag of leather, tarpaulin, &c. duly marked.

In order to give more room, all articles, of the same description in particular, should be placed so as to lock into each other, or to fit in such manner as may leave the least possible intervals. A person should attend to register, not only the several articles as they should be shipped, but to note the exact part of the hold, &c. where each might be stowed. These precautions, added to the affixment of particular marks, such as numbers, in white paint, on each bow, and each quarter of every transport, so as to be distinguishable at several miles distance, will tend considerably to facilitate the debarkations; and enable the several commanders and public officers to ascertain with perfect precision the amounts of losses, and the situations of the several stores, according as vessels may lie to windward, or to leeward, &c. It is a matter of considerable importance in embarking stores, to have them ready at hand which would be the first wanted in case of emergency: as well as to arrange them in such manner as should answer the purposes of the expedition in the most efficacious manner. Thus, if it is expected that troops will have to disembark in the presence of an enemy, the light field-pieces, and howitzers, in lieu of being sent below, ought to be kept, together with all their implements, and a certain portion of their ammunition in some secure part, whence they could be lowered into the boats at a short notice. Entrenching tools should

also be held in equal readiness, together with abundance of sand-bags. When troops are to be embarked, every precaution must be taken to prevent confusion, and to obviate danger. Certain corps should be appointed to be in readiness on given days at particular ports; taking with them only such baggage as should be allowed on the occasion. The stores of every description and the disposable lumber should be previously sent on board, under charge of the quartermaster, who should be particular in seeing that every thing necessary to the comfort and efficiency of the troops were duly arranged. The transports being in readiness, they should, if possible, be brought up to a pier, so that, by the aid of gang-boards, the files might march on board at once; otherwise recourse must be had to boats and small craft, in which the troops must proceed from the shore to the shipping. The lee-side is generally preferred for embarking; it being the smoothest water, and often the ascent up the gang-ladder less difficult. The safest mode is for the arms to be handed up into the main chains, and from thence into the vessel. The bayonets ought to be well secured to their scabbards, and the pouches should be buttoned down. The men nearest the gang-ladder should be the first to ascend; the others taking care to balance the boat, &c. as she becomes lighter, and requiring equipoise in consequence of being quitted by the troops. It should be observed as a standing regulation never to let one boat lie abreast of another that is discharging her crew into a vessel: otherwise there will not only be danger of broken-legs, but of being upset: each boat should range up under the lee-quarter, in succession, and when evacuated by the troops should pull a-head, by means of a painter, or a boat-hook, so as not to impede its successor. When the troops are on board boats, they should sit as low as possible, keeping their muskets perpendicular, and rested on the bottom, or on their own feet. In going on board the men should proceed very leisurely and silently to their places, spreading so as to preserve the due time of the boat, and sitting down so soon as duly arranged. In case of accident, or running foul of any other vessel, they should be particularly enjoined to remain seated, and not to obstruct the boat's crew in their endeavours to remedy the mishap. Where troops are to embark in the face of an enemy, the greatest order and coolness will be requisite; especially when within the reach of their cannon. If the embarkation in boats is to be made from a ship, they must all be manned from that side least exposed to the enemy's fire; the ship covering them as they successively put off, and rest on their oars, until the whole may be ready to start together by signal; after which no time should be lost in gaining the shore, and in forming on the beach. It sometimes occurs, that a river is to be crossed in boats for the attack of an enemy posted on the opposite bank: in such case, the number of boats being previously ascertained, the troops must be told off into as many divisions as there may be vessels to convey them, the strength of each division corresponding with the tonnage of that it is to occupy. Each division then proceeds on board with rapidity, but with perfect regularity, and the whole put off without delay. Where the water is rather shallow, the boats must lie out so far as to be afloat after the men have, by wading, got on board. All debarkations from boats and shipping should be conducted with as much order as circumstances may admit; and even when troops are driven back to their boats, as much should be preserved as the pressure of pursuit may allow. It is a well-known fact, that many re-embarkations have taken place in the presence of a superior force without disorders, or allowing the enemy to make a single prisoner. The greatest danger generally

arises

arises from allowing the boats to lie in so close, as to touch the ground, whereby, when the troops have got on board, they have been unable to push off, and thus remained subject to a galling fire. When re-embarking after a repulse, it should be studied to man some of the craft, (especially a few of the lightest construction, and any gun-boats whose draught of water may allow them to lie near the beach,) for the purpose of covering the retreat, and to take in flank such of the enemy as should follow the fugitives into the water. When such a precaution is observed, the embarkation will proceed quickly, and the enemy will content themselves with a distant fire on the retreating force; in lieu of mixing pell-mell, as they would do if there existed no pre-established check. Troops embarked on board transports, or ships of war, are only allowed three-fourths of a seamen's ration of provisions; unless when acting as marines, when they are on a footing. The messes are formed of six men in each, for each of which a space of six feet square is allowed, that is, 36 square feet; but only four are ever there at the same time, it being a rule that one-third of each mess should always remain on deck. When embarked for foreign service, six women are allowed provisions for every hundred men; and when on home service, ten women are allowed with the same number. That part of the charter-party which relates to the provision, firing, candles, utensils, &c. intended for the use of the troops, is always subject to the inspection of their commanding officer on board; and is sometimes copied out, and hung up in the cabin, open to the perusal of all. The regulations regarding smoking, extinction of lights, &c. are also posted up in various parts, together with the whole allotment in regard to births, messes, and particularly the accommodations for the officers of the vessel, and those attached to the troops. It being necessary to establish some limit for the quantities of baggage taken on board, the following proportions were fixed for that purpose.

For a field-officer	-	-	five tons.
For a captain	-	-	three tons.
For a subaltern	-	-	a ton and a half.

General officers are rarely limited, but it is usually intimated to all embarking, that the quantity of baggage should be reduced as much within bounds as might be practicable.

The embarkation of horses is usually effected by means of slings of canvas, which passing under their bellies, and being duly secured with cords, enable the crew to hoist them in, and to lower them down between decks without doing the smallest injury to the animals; which, however spirited they may be while on terra firma, generally become perfectly passive under such circumstances. On arriving at the place of destination they are debarked in the same manner. It certainly is among the most important improvements in this branch of service, that the horses can be slung, during bad weather, to the beams in such manner as to prevent their suffering in consequence of the ship's motion. Yet we cannot but judge, from the crippled state in which cavalry are sometimes debarked, that much room remains for improvement.

**EMBARRAS, EMBARRASMENT**, a French term, though now naturalized; denoting a difficulty, or obstacle, which perplexes or confounds a person, &c.

**EMBASIS**, in the writings of the *Ancient Physicians*, the name of a large vessel, in which they prepared their medicated baths, and which was capable of holding the person to be bathed at his full length.

**EMBASSADOR**, or **AMBASSADOR**, is a public minister.

ter sent from one sovereign prince or independent state to another, as a representative of that prince or state, and furnished with credentials which verify his mission as an ambassador.

Such a public minister is called in Latin *legatus*, or *orator*, but the meaning of the word ambassador is much more extensive. The only circumstance in which the modern ambassador and the ancient *legatus* agree is the protection of the law of nations. See **LEGATION**.

The English word ambassador is probably derived from the Spanish *embaxador*, the same as the French *ambassadeur*, which comes from *ambasciator*, a Latin word of the middle age, formed of *ambascius*, or *ambasci*, an agent, domestic, or client among the Gauls. The term *ambascia* is found in the Salic law, Tit. xix. and in the law of Burgundy.

The custom of sending ambassadors dates from the origin of civil societies. As soon as mankind were divided into distinct nations, differences would arise which must be amicably settled by the interference of neighbours, guarded against by the protection of the more powerful, or decided by wars ending in reconciliations. The negotiating of these mediations, alliances, and treaties of peace is entrusted to public ministers; and sovereign princes having, like private persons, interests to discuss with other princes regarding their own concerns as individuals, such as the contracting of matrimonial alliances; the management of these transactions is likewise confided to public ministers, or negociators. See **NEGOCIATION**.

Among the public ministers sent as negociators, from one independent state or sovereign prince to another, ambassadors hold the first rank. Envoys, ministers plenipotentiary, and residents, are negociators of less eminence. (See **ENVOY**, **PLENIPOTENTIARY**, and **RESIDENT**.) Their functions are the same; they are equally under the protection of the law of nations, and they enjoy nearly the same privileges.

The pre-eminence of ambassadors manifests itself chiefly in the particular ceremonial of their reception in the country where they are appointed to reside. They are entitled to be saluted with the firing of guns; to be complimented by deputies of the prince or state to which they are sent; to make a solemn public entry; to speak at the audiences they obtain with their heads covered; to have places of honour assigned to them at all public ceremonies; to keep a canopy or throne in their dwelling; and, since the year 1593, when this title was first given them at Rome, to be styled excellencies. The name of ambassador, Cicero observes, is sacred and inviolable: "non modo inter sociorum jura, sed etiam inter hostium tela incoluma versatur;" (In *Verr. orat.* 6.)

The privileges which ambassadors share with other public ministers, sent as negociators, are.

1. The right of being received by the prince or state to which they are deputed, unless there be a just cause for refusing to receive them. The duke of Buckingham, says Hume, had English familiarity, and French levity, two of the most offensive qualities in an ambassador. When, in 1626, he was desirous of being once more ambassador at the French court, it was signified by the French ambassador to the court of St. James's that for reasons well known to the duke his person would not be agreeable to his most Christian majesty. His presumption to talk of love to the queen in a former embassy had given offence, and would have been a just cause for his non-admission.

The corresponding obligation of receiving foreign ambassadors has its foundation in the dearest interests of society and of humanity. As nations are in continual need of mutual assistance, they could never freely communicate, if the

law of nations had not made it an imperious duty to all states to admit the ambassadors who are sent to them. Even the ambassadors of an enemy have a right to be received and to be heard, since it is the duty of nations at war with each other to endeavour by all possible means to re-establish the accustomed relations of peace and amity.

2. The inviolability of their persons. Ambassadors represent the sovereign or chief magistrate of an independent state; their missions are frequently of the most delicate nature, and could not be accomplished if the security of their persons were not expressly provided for. Those who insult an ambassador infringe not only the civil law, which forbids the doing of injuries in general, but more particularly the public law of nations, which extends its special protection to public ministers, that the harmony of nations may not be disturbed, or if unfortunately the ties of friendship have been broken, that the effecting of a reconciliation may labour under no restraint. The smallest insult offered to an ambassador ought to be punished with the greatest severity; the neglect to punish the offender is a just cause of war.

If an ambassador grossly offends, or makes an ill use of his character, he may be sent home, and accused before his master: who is bound either to do justice upon him, or avow himself the accomplice of his crimes. (Mont. Sp. of L. 26. 22.) But writers on the law of nations are not agreed, whether this exemption of ambassadors extends to all crimes, as well natural as positive: or whether it only extends to such as are *mala prohibita*, as coining, and not to those that are *mala in se*, as murder. Our law seems formerly to have taken in the restriction, as well as the general exemption. For it has been held, both by our common lawyers and civilians (1 Roll. Rep. 175. 3 Bulst. 27.) that an ambassador is privileged by the law of nature and nations; and yet if he commits any offence against the law of reason and nature, he shall lose his privilege (4 Inst. 153.); and therefore, if an ambassador conspires the death of the king in whose land he is, he may be condemned and executed for treason; but if he commits any other species of treason, it is otherwise, and he must be sent to his own kingdom. However, the general practice of this country, as well as of the rest of Europe, seems now to pursue the sentiments of the learned Grotius, that the security of ambassadors is of more importance than the punishment of a particular crime. And therefore few, if any, examples have occurred within a century past, where an ambassador has been punished for any offence, however atrocious in its nature.

Even the domestics and the persons in the retinue of an ambassador are inviolable. If any one of them were insulted, the punishment ought to be as severe as if the insult had been offered to the ambassador himself. The domestics of the duke of Créqui, French ambassador at Rome, having been insulted by the Corsican guards of Pope Alexander VII. Louis XIV. insisted upon their being severely punished.

But this inviolability extends only to the persons who compose the ambassador's family, as his wife and children, and who being actually in his retinue are registered as such by the police of the country where he resides. Should, however, any of them be guilty of a great crime, as a forgery, theft, or murder, it would be no violation of the law of nations to claim the offender, and to punish him according to the laws of the country. When Sully resided in England as ambassador of Henry IV of France, he was informed that one of his gentlemen had killed an Englishman in a house of ill fame. He immediately got him arrested, and sent word to the magistrates of London that they might

seize the murderer. The latter having been tried, the king of England granted him his pardon and his liberty.

In consequence of this inviolability the actions of an ambassador or of any person in his retinue are not subject to the controul of the private law of the country in which he is appointed to reside; and with regard to civil suits they cannot be prosecuted for any debt contracted in that country as long as the ambassador continues in it in his public capacity. This privilege is allowed in the English courts of law, and, the more effectually to enforce the law of nations in this respect, when violated through wantonness or insolence, it is declared by the statute 7 Ann. c. 12. (an act passed in 1708, in consequence of the arrest of an ambassador from Peter the Great, czar of Muscovy, for a debt of 50*l.*) that all process whereby the person of any ambassador, or of his domestic or domestic servant, may be arrested, or his goods distrained or seized, shall be utterly null and void; and that all persons prosecuting, soliciting, or executing such process, being convicted by confession or the oath of one witness, before the lord chancellor and the chief justices, or any two of them, shall be deemed violators of the laws of nations, and disturbers of the public repose; and shall suffer such penalties and corporal punishment as the said judges, or any two of them, shall think fit. But it is expressly provided, that no trader, within the description of the bankrupt laws, who shall be in the service of any ambassador, shall be privileged or protected by this act; nor shall any one be punished for arresting an ambassador's servant, unless his name be registered with the secretary of state, and by him transmitted to the sheriffs of London and Middlesex. These exceptions are strictly conformable to the rights of ambassadors, as observed in the most civilized countries. In consequence of this statute, thus declaring and enforcing the law of nations, these privileges are now held to be part of the law of the land, and are constantly allowed in the courts of common law. (Fitz. 200. Stra. 797.) Blackstone's Commentaries, vol. i. and iv.

3. The most perfect freedom and independence in the discharge of their official duties. This is a further consequence of their inviolability. If an ambassador should even excite disturbances, or enter into any conspiracy against the prince, or the state to which he is sent, the general practice of Europe is in favour of the opinion of the learned Grotius, in his book "De Jure Belli et Pacis," that the inviolability of an ambassador is of greater importance than the punishment of a particular crime. His public character ought to be constantly and invariably respected; but he may be dismissed, and sent back to the prince or state whose representative he is. The bishop of Rois, ambassador of the queen of Scotland at the court of Westminster, having engaged in a conspiracy with the duke of Norfolk against the queen, he was arrested, confronted with his accomplices, and sent back to Scotland. In the reign of Henry IV. of France, the Spanish ambassador took a part in the conspiracy of the count d'Auvergne and duke d'Angoulême, who were both tried; but no mention was made of the ambassador. A certain Mérargues had agreed, with the secretary of the same ambassador, to deliver Marseilles into the hands of the Spanish monarch. The French parliament condemned Mérargues to death; but the Spanish secretary was delivered to the king of France, who gave him up to the Spanish ambassador, and obliged the latter to send the secretary out of the kingdom.

If an ambassador be dismissed and escorted to the frontiers, he is entitled to the privileges and immunities of his dignity, as long as he is on the territory of the state that sends him back. He ought also to be allowed a convenient time

to prepare for his departure. This indulgence must even be granted to the ambassador of a power against which a declaration of war has been issued, and he must be furnished with passports to return home unmolested. The custom of the Turks, who, in the case of war being declared, confine the ambassador of the power against which it is declared in the castle of the Seven Towers, is in direct violation of the law of nature, and of the public law of nations. The enlightened sovereigns of Europe should join in remonstrating against so unjust a practice, and insist upon its abolition.

4. The inviolability of the house in which they reside. An ambassador's dwelling is a sacred asylum, where no person can be arrested without the ambassador's consent. Any felon, however, that might have taken refuge in an ambassador's house, ought to be given up to the criminal justice of the country.

Neither have ambassadors the right of trying or punishing, within the walls of their mansion, persons of their retinue who have been guilty of any crime. Though independent of the criminal and civil laws of the country in which they reside, they cannot exercise any judicial functions, because the judicial power of the sovereign they represent does not extend to that country.

5. The right of having divine service performed in their houses, at a chapel of their own, according to the rites of the worship of their country: but ambassadors cannot claim the free access of others to their chapel than the subjects of the country they represent, who are under their special protection in this respect. At the time when the Protestants were cruelly oppressed and persecuted in France, the French Protestants residing at Paris have frequently been molested in going to and coming from the chapel of the Dutch ambassador; but he had no right to remonstrate against this cruelty, because it was exercised on the subjects of the king of France.

6. The right of being exempt of all duties, charges, taxes, imposts, excise and custom dues. This right has sometimes been restricted in countries where it had been abused by ambassadors, who, forgetful of their dignity, had not scrupled to make it a cover to an illicit trade.

7. The privilege, that in case of death, the household furniture, moveables, and personal property of ambassadors, or of any individual in their retinue, devolve to their heirs, though aliens, without being liable to any deduction, tax, or alien duty, commonly called "Droit d'Aubaine." But this right does not extend to immoveables, or landed property.

8. The right of legalizing or certifying the authenticity of documents or writings which are to be transmitted to the state or country which they represent, and that of granting passports to the natives of that country.

9. The right of following the court at which they are appointed to reside, to whatever place that court is removed to, unless the prince should declare his absence to be merely temporary, and request the ambassador's non-attendance. During the seven years' war in Germany, from 1756 to 1763, the English ambassador at the court of Berlin attended the great Frederick of Prussia at all his headquarters.

10. Lastly, ambassadors consider themselves as entitled, and indeed custom appears to have sanctioned it as a right, to receive some valuable trinkets as presents at their last audience, when they take leave of the prince at whose court they have resided.

Embassadors ought to be very attentive not to suffer any of their privileges or immunities to be infringed upon; neither ought they to pass over any attack on the person or

dignity of the prince, or on the character of the state they represent. Whenever they have a complaint of a breach of privilege to prefer at the court where they are appointed to reside, they are supported in their demands of redress by the whole diplomatic body, or corps diplomatique, that is to say, by the aggregate of all the foreign ministers residing at the same court.

But ambassadors cannot claim their privileges and immunities, unless they have proved their mission as ambassadors by the delivery of their credentials; nor can they display their character of public ministers in any other country than that to which they are sent in that quality. When they are under the necessity of traversing the dominions of any other sovereign prince, they must provide themselves with the permission to travel through that country by means of regular passports, for the law of nations does not oblige a prince or nation to respect an ambassador on his journey through their country, if he should attempt to traverse that country without having previously obtained their permission.

At Athens the ambassadors from foreign princes and states always mounted the tribunal, or pulpit, of the public orators, and there opened their commission, and acquainted the people with their business. At Rome they were introduced to the senate, and delivered their commission to them. Among us they make their address immediately and solely to the king.

Athens and Sparta, says M. Tourneil, when in all their glory, were never so much delighted as to see and hear a number of ambassadors in their assemblies, suing for their protection or alliance. It seemed to them the noblest homage that could be paid them; and that state which received the most embassies, was judged to have the advantage over the other.

There are some usages to which ambassadors ought to conform. They should never attend at any marriage, christening, funerals, or other private solemnity; nor must they even go into mourning on any occasions of their own, because they are no longer private individuals; they are the representatives of a sovereign prince or independent state.

Embassadors, in modern times, are either *ordinary* or *extraordinary*.

An *ambassador ordinary* is he who constantly resides at the court of a sovereign prince or independent state, to maintain a mutual good understanding between the two states, to watch over the permanent interests of his country, to transact such affairs as may occur, and to give a regular account of his proceedings and observations to the prince or state which he represents. The practice of keeping ambassadors ordinary in foreign courts is but of modern invention. It is generally ascribed to the cardinal de Richelieu. Raymond de Beccaria, baron de Forquevaux de Pavie, knight of the order of St. Michael, was one of the first public ministers who resided permanently at a foreign court. He was sent to Spain in 1565, as ambassador ordinary of Charles IX. of France at the court of Philip II. probably on account of the misunderstanding which prevailed between the Spanish monarch and his consort Elizabeth, who was a French princess.

The frequent intercourse which takes place between modern nations; the many relations in which they stand to each other; their mutual interests; their political and commercial jealousies; the wish of being rapidly and confidently informed of their respective projects, enterprises, connections and partialities, of the springs by which their governments are set in motion, and of the general administration

## EMBASSADOR.

of their concerns abroad and at home; and lastly, the want of a powerful protection for individuals trading in foreign countries, are indeed circumstances which confer on the permanent residence of public ministers in foreign courts a high degree of public convenience and utility. Every independent European state has adopted the practice, except the Helvetic Republic, and the sublime Ottoman Porte. These two states have hitherto at least employed only ambassadors extraordinary.

An *ambassador extraordinary* is he who is sent from one sovereign prince or independent state to another on some particular occasion or emergency, and who retires as soon as the business of his mission is terminated. Hence it follows that an ambassador extraordinary may be dispatched to a court or country where an ambassador ordinary of the same prince or state is permanently residing. Thus the king of Great Britain appointed Mr. Rose ambassador extraordinary to the United States of America in 1808, for one particular purpose, whilst the honourable Mr. Erskine continued as British ambassador ordinary at Washington.

In ancient times, all embassies were extraordinary. They were generally undertaken from motives of necessity, policy, or adulation, sometimes even from the mere love of magnificence, and commonly composed of a great number of ambassadors. This used also to be the case with the extraordinary embassies of the Swiss, because every canton appointed its ambassadors. The embassy which Switzerland sent to the king of France in 1663, consisted of forty-two ambassadors.

In our days, extraordinary embassies of more than one ambassador, are very rare; at least they never consist of more than three ambassadors. Their number, however, is noways limited by the public law of Europe; neither is the retinue or train of an ambassador extraordinary restricted to any particular number of persons. It ought only not to be so numerous as to create any uneasiness in the country where the ambassador extraordinary is appointed to sojourn for a short time. The duke of Feria, who went to France as ambassador extraordinary of the king of Spain, to compliment Louis XIII. on his accession to the throne, after the death of Henry IV. had so numerous a retinue, that the governor of Bordeaux refused to admit him in that city. He assigned him his quarters in one of the suburbs, and wrote to inform him, that he could not admit him in the place, because his train formed a small army, which might easily assail the governor with a thousand firelocks. This cautious conduct of the governor was fully approved of at the French court.

Extraordinary embassies are generally very brilliant. The earl of Manchester's public entries into Venice as extraordinary English ambassador in 1698 and 1701, are described as uncommonly magnificent. His excellency was attended by sixteen footmen, and six pages, dressed in velvet and gold brocade, besides his secretary, and a considerable number of English gentlemen.

The ambassador extraordinary has the precedence before the ambassador ordinary of the same power. When it happens that an ambassador extraordinary is sent to the same court after another ambassador extraordinary, he who is last arrived has the precedence, unless the prince or state by which they are appointed determines their rank differently. When ambassadors ordinary are relieved, he who is going to quit the court or country where he has resided walks at the right of his successor in proceeding to the audience: but, in returning, he gives the right to the new ambassador, because his functions are terminated by the farewell audience.

With respect to the rank of foreign ambassadors residing at the same court among themselves, the nuncio of the pope was always considered as holding the first rank at the French court before the establishment of the French republic in 1792. He used to compliment the king on particular occasions in the name of the whole diplomatic body. In other courts the French ambassador had the precedence before the ambassadors of any other kingdom. The Spaniards alone disputed his pre-eminence for a time: but it was solemnly recognized by Spain in 1662, and no other power did ever dispute it. The French ambassador claimed even the precedence before the Russian imperial ambassador. M. D'Esterno, the French ambassador at the court of Berlin in 1786, found himself highly offended, that the queen of Prussia, consort of the late Frederick William II. sat down to cards with the Russian ambassador, whilst he was only invited to take a hand with the princess Friderika, eldest daughter of the king of Prussia, at present duchess of York.

The right of sending ambassadors is generally vested in the prince or chief magistrate, to whom the exercise of the executive power is entrusted in independent states. It is an essential attribute of sovereign power. Yet it is not absolutely necessary that a prince be in the actual possession of this power to appoint ambassadors; provided he have not abdicated the crown, his ambassadors ought to be received at other courts, unless there be some political motives for refusing their admission: but even in that case they are like other public ministers, under the special protection of the public law of nations.

The actual possession of the sovereign power, whatever may have been the means by which it has been acquired, is considered as a sufficient title to the right of sending ambassadors, and the ambassadors of an usurper have often been admitted in courts where those of the lawful prince have been refused. The ambassadors of Cromwell were received in France, when Charles II. himself could not obtain an audience.

To admit an ambassador, is to acknowledge the sovereignty of the prince, or the independency of the state which he represents. France acknowledged the independence of the United States of America, by admitting Franklin as their ambassador before they were declared independent by Great Britain.

During the minority of a monarch the regent may appoint ambassadors, but always in the name of the king. They represent him in whom the executive power is vested by the constitution and not his substitute. It is this representative dignity which subjects the proceedings and motions of ambassadors to formalities and ceremonies that frequently impede and obstruct their negotiations. Hence it is not unusual to appoint a simple minister plenipotentiary to carry on an important and difficult negociation, but to furnish him at the same time with the credentials of an ambassador extraordinary, with the strict injunction not to make any use of them unless he should be successful in his mission. In that case he delivers them only at the close of the negociation, just before the signing of the treaty, which derives a certain additional solemnity for being signed by an ambassador extraordinary.

As the functions of an ambassador consist in watching in the country where he is appointed to reside over the interests of the state which he represents, in making regular reports of his proceedings, and in communicating every circumstance, the knowledge of which is deemed of importance to the minister at the head of the department for foreign affairs in his own country, it follows that an ambassador ought to be well acquainted with the political state and

the language of the country in which he resides, with the temper and disposition of the prince or chief magistrate by whom it is governed, with the particular character of the minister who manages its foreign affairs, with the relations of that country with the other powers of Europe, and with the particular policy which influences them towards that country. To this indispensable political information an ambassador ought to join a consummate knowledge of mankind in general, an incorruptible integrity, an enlightened prudence, a sagacious judgment, mild and refined manners, an insinuating address, a generous disposition, sound discretion, and dignified firmness, and above all a great command over himself. This catalogue of qualities, which are rarely combined, shews how difficult it must be to find fit subjects for embassies. There is in France a sort of diplomatic gradation through which all individuals employed in missions to foreign courts are generally obliged to pass. The first step is that of secretary of legation of the second class, then follows that of secretary of legation of the first class; the third step is that of minister plenipotentiary, and the fourth that of ambassador. Frequent exceptions, however, take place with regard to the appointment of ambassadors, who are sometimes taken from the army. (Wicquefort. *Pembassadeur et ses fonctions*. Pecquet. *discours sur l'art de négocier*. L'esprit de Leibnitz, tome ii. Chesterfield's letters ccii. ccxix. elii. cclxxxviii.)

EMBASSADRESS, in French *Ambassadrice*, is, in the common acceptation of the word, the wife of an ambassador, who as such shares his rank and privileges. But there have been ambassadresses in their own right, or female ambassadors. The famous league of Cambray was signed, in 1508, on the part of the emperor, by Margaret of Austria his daughter, to whom he had given full powers for that purpose. The peace concluded at Cambray, in 1529, in confirmation of that of Madrid, was also signed by the same Margaret of Austria, duchess of Parma, in the name of Charles V. and by Louisa duchess of Savoy, mother of Francis I. by virtue of full powers given to these two illustrious ladies by the emperor and the king of France. In the year 1645, Louis XIV. expressly appointed Madame la Maréchale de Guébriant his ambassadress extraordinary, to consign Mary de Gonzagues, daughter of the duke of Nevers, to the arms of her royal husband, the king of Poland, who had married the princess by procurator. Circumstances might indeed arise in which a lady might with great propriety be appointed ambassadress at the court of a sovereign princess, into whose confidence she might more easily insinuate herself than an ambassador. In such cases she would be under the special protection of the law of nations, and enjoy all the rights and immunities of an ambassador.

EMBASSY, formerly *Embassage*, in French *Ambassade*, *legatio*, is the charge or office of an ambassador, or any other public minister sent to represent one sovereign prince or independent state at the court of another. It also denotes the solemn message, mission, or errand, on which such a public minister is sent.

F. Daniel observes, that under the ancient French kings, their embassies consisted of a body, or number of persons, joined together in commission, and who composed a kind of council; something like which is still retained at treaties of peace. Thus the French embassy at Nimeguen, for the peace consisted of three plenipotentiaries; that of Utrecht, of two, &c. See EMBASSADOR.

EMBATTLED, a term in *Heraldry*, when the outline of any ordinary is notched so as to represent the battlements of a wall, or castle. See BATTLEMENT.

None were suffered, in ancient times, to embattle their houses, but those who had great dignities, as the barons, and the like. Camden proves this in his account of Tunstall's seat in England, in which he expresses it as a signal mark of the royal favour, that he had liberty given to embattle it. The heralds express this embattled line by the term *crenelle*; and when it has the embattling on both sides, which is the more rare, they call it *brétesse*; which see.

EMBAUL, in *Geography*, a town of Africa, in the kingdom of Damel. N. lat. 15° 15'. W. long. 15° 37'.

EMBDEN. See EMDEN.

EMBELIA, in *Botany*, corrupted from the Ceylon name Aembillia. Burm. Ind. 62. t. 23. Juss. 427. (Ribesioides; Linn. Fl. Zeyl. 190.) Class and order, *Pentandria Monogynia*. Nat. Ord. uncertain. Juss.

Gen. Ch. Cal. Perianth small, five-cleft, inferior. Cor. Petals five, regular, undivided. Stam. Filaments five, equal; anthers . . . . Pist. Germen simple, superior; style one; stigma . . . . Peric. Berry . . . .

A smooth shrub, without thorns. Leaves alternate, oblong, entire. Flowers in terminal panicle clusters. Fruit white, acid, used for making rob or jelly. Native of Ceylon. Schreber, by his index, seems to refer this plant to *Anidefina*, but their characters do not accord.

EMBER-GOOSE, in *Ornithology*, the *colymbus immer* of Linnæus; which see.

EMBER-WEEKS, are those wherein the ember or embering days fall.

In the laws of king Alfred, and those of Canute, these days are called *ymbren*, that is, *circular days*, from whence the word was probably corrupted into ember days. By the canonists, they are called "quatuor anni tempora," the four cardinal seasons, on which the circle of the year turns; and hence Henshaw takes the word to have been formed, viz. by corruption; from *temper*, or *tempora*. The ancient fathers called them "quatuor tempora jejunii."

Mr. Somner thinks they were originally fasts, instituted to beg God's blessings on the fruits of the earth. Agreeably to which, Skinner supposes the word ember taken from the ashes, embers, then strewed on the head.

The ember days are the Wednesday, Friday, and Saturday, next after Quadragesima Sunday, or the first Sunday in Lent, after Whitsunday, after Holyrood-day in September, and after St. Lucy's day in December; which four times answer well enough to the four quarters of the year, spring, summer, autumn, and winter. These days are mentioned by Britton, c. 53, and other writers; and particularly in the stat. 2 and 3 Edw. VI. c. 19.

These ember weeks are now chiefly taken notice of on account of the ordination of priests and deacons; because the canon appoints the fundays next succeeding the ember-weeks for the solemn times of ordination; though the bishops, if they please, may ordain on any Sunday or holiday.

EMBERIZA, in *Ornithology*, a genus of the Passerine order, the character of which consists in the bill being couic; mandibles receding from each other from the base downwards, the lower with the sides narrowed in, and a hard knob within the upper mandible. This last-mentioned process in the mouth is adapted in a very peculiar degree to the manners of the emberiza tribe; all the species feed on seeds, and by the aid of this knob they are able to break and comminute the shells of the harder kinds with facility. The genus is extensive, and includes some very beautiful birds.

Species.

## EMBERIZA.

### Species.

**NIVALIS.** Quill-feathers white, primaries black on the outer edge; tail-feathers black, the three lateral ones white. Linn. *Hortulanus nivalis*, Briss. *Ortolan de neige*, Buff. *Pied mountain finch*, Albin. *Snow bunting*, Lath. *Donov. Brit. Birds.*

Inhabits the northern parts of Europe, Asia, and America, during summer, and migrates to warmer climates in the winter. Its size rather exceeds that of the chaffinch; it builds in cavities of rocks and lays five eggs, which are of a white colour, spotted with brown. The species varies considerably in its plumage at different seasons of the year, and three distinct kinds are described as permanent varieties. One variety is white, with the feathers dashed with yellow, and the chin and throat marked with very small brown spots. This is called by Frisch Weis's Fleckige Ammer. Another (*hortulanus nivalis pectoris nigro* of Brisson), is yellowish-white above, beneath with the breast black; wings and tail black and white intermixed. The pied chaffinch of Albin is the third; the body of this is reddish-brown; head and neck white, breast with a blueish spot; wings and tail varied with black and white.

**MUSTELINA.** Quill-feathers dusky, white at the base, the last entirely black; tail-feathers black; middle ones at the edge, and three lateral ones each side, white with a dusky spot without. Gmel. *Emberiza nivalis*, Linn. *Emberiza glacialis*, Lath. *Tawny bunting*, Brit. Zool.

About the same size as the former, and is by some writers erroneously confounded as a variety of it. The species occurs rarely in the northern parts of Britain.

**MONTANA.** Five first quill-feathers blackish-brown, the rest white, spotted with brown at the tip; tail-feathers brown; three lateral ones each side entirely white. Gmel. *Lesser mountain brambling*, Willughby. *Mountain bunting*, Lath. *Donov. Brit. Birds.*

Found in Yorkshire and Lincolnshire.

**HYEMALIS.** Black, belly white. Gmel. *Fringilla hyemalis*, Linn. *Passer nivalis niger*, Kalm. *Ortolan jacobin*, Buff. *Snow bird*, Catesby. *Black bunting*, Lath.

The length of this bird is about six inches and a half. During winter, and more especially in snowy weather, it is seen in Virginia and Carolina; its summer place of residence is unknown. By some it is called the chuck-bird. The flesh is held in esteem as an article of food.

**MILIARIA.** Brown, beneath spotted with black; orbits rufous. Linn. *Alauda congener*, Aldr. *Strillozzo*, Olin. *Cynchramus*, Briss. *Gerst-ammer*, Gunth. *Le Poyer*, Buff. *Common bunting*, Lath. *Donov. Brit. Birds, &c.*

Common during the summer and autumn in most parts of Europe; in England they remain throughout the winter, but in the more southern climates migrate at the approach of that season. They associate in flocks. The females build their nest in a low hedge, or on a stump near the ground, and lay from five to six eggs. These birds are rather larger than the yellow-hammer, and in the appearance of their plumage so closely resemble the lark, that they are commonly sold under the name of bunting larks in the London markets. They are caught in vast numbers for sale during the winter season; the flesh is bitter, and inferior to that of the true lark.

**HORTULANA.** Quill-feathers brown, the first three whitish at the edges; tail-feathers brown, the two lateral ones black on the outer side. Linn. *Hortulanus*, Gessn. *Ortolano*, Olin. *Ortolan*, Lath.

The varieties of this species are numerous; the principal are  $\beta$  (*ortolan jaune* of Buff.); the plumage of which is yellowish,

with the quill-feathers edged with white;  $\gamma$  (*ortolan blanc*) snowy white;  $\delta$  (*hortulanus quintus* of Ray) which has the tail white; and  $\epsilon$  (*ortolan noiratre* of Buff.) the colour of which is blackish, head and neck greenish, bill red, and legs cinereous.

These birds are found chiefly in the south of Europe, from whence they migrate northwards as far as Sweden, but have not been known to visit England. The size is that of our yellow-hammer, and its song is not very dissimilar to the notes of that common bird, but more melodious; its nest is usually built in a low hedge, or on the ground, and contains five eggs of a greyish colour. The celebrity of the ortolan for the tables of epicures is perfectly well known; they are caught for this purpose in vast number at the times of their periodical migrations in spring and autumn, and fattened in a peculiar manner. Their feeders place them in a dark room, with an abundance of oats and millet, upon which they feed with avidity, and become in a very short time extremely fat, in which state they weigh sometimes three ounces each. When thus fed they are considered exquisitely delicious, and fetch a high price. Ortolans are taken in great numbers in the south of France and Italy, some parts of Germany, and the southern provinces of Russia and Siberia; and are potted or otherwise preserved, and form an article of exportation to those countries where these delicious birds are less commonly found.

**SINENSIS.** Reddish brown, beneath pale yellow; lesser wing-coverts yellowish; quill and tail-feathers with the longitudinal streak on the belly brown. Lath. *Ind. Orn.* *Ortolan de la Chine*, Sonner. *Chinese bunting*, Lath.

Inhabits the southern provinces of China during the months of October, November, and December. Size not mentioned.

**CITRINELLA.** Tail-feathers blackish, the two outer ones on the inner edge with a pointed white spot. Linn. *Emberiza flava*, Gessn. *Zivolo*, Olin. *Braunt*, Buff. *Yellow-hammer*, Ray. *Donov. Brit. Birds.*

A general inhabitant of Europe, in every part of which it appears to be common. The male differs from the female in having the colours of the plumage more obscure, and the head only tinged with yellow; in the male the head is of a very vivid yellow, whence its name. The nest of this common bird, as is well known, consists of hay, and other dry substances, slightly put together, and placed either on the ground or in a bush close to it: the eggs from four to five in number, and of a grey colour with streaks, and a few blotches of brown. These birds are eaten in Italy.

**OLIVACEA.** Olive, beneath whiter; chin orange; pectoral band blackish. Gmel. *Emberiza dominicensis*, Briss. *Olive*, Buff. *Olive bunting*, Lath.

Inhabits St. Domingo, and is about the size of the common wren.

**PASSERINA.** Above grey-ferruginous; middle of the feathers black beneath, whitish-ash spotted on the sides; tail-feathers black, the middle ones edged with ferruginous; the outer one each side nearly to the base, the next as far as the middle obliquely white. Pallas. *Passerine bunting*, Lath.

Size of the reed sparrow. The head and chin in the male black; behind the eyes a pale streak; tail rather forked; legs brownish flesh colour. Inhabits Russia near the Ural, and Jaick.

**PUSILLA.** Above grey-ferruginous; beneath whitish; throat spotted; head with alternate longitudinal testaceous and black bands. Pallas.

A small

## EMBERIZA.

A small species, found among the snowy mountains of Dauria.

**RUSTICA.** Head black, with three longitudinal white bands, chin, body beneath, and two outmost tail-feathers each side obliquely white. Pallas.

Inhabits Dauria, chiefly in woody situations.

**FUCATA.** Grey-ferruginous; ears with a round rufous spot; eye-brows, line beneath the eyes and throat white; chin furrounded with a brown spotted circle. Pallas.

Frequent in rocky parts of Siberia.

**SPODOCEPHALA.** Grey-ferruginous, beneath pale straw colour; frontlet black; head and neck hoary-ash. Pallas.

Inhabits near the waterfalls in the Alpine regions of Dauria. Size of the reed bunting.

**CHRYSOPHRYS.** Grey-ferruginous; crown black; eye-brows citron, from the middle of the crown to the nape a white band. Pallas.

Found with the latter; size of the common yellow-hammer.

**MAELBYENSIS.** Head and neck lead-cinereous; chin whitish; belly ferruginous. Sparman, Mus. Carl.

Described from a specimen taken at Maelby, in Sweden, a seat of count Carlson, in the dukedom of Sudermania. Some writers suggest that the bird mentioned might be either the female or young of the pine bunting.

**RUTILA.** Sanguineous rufous; beneath sulphur; wings grey rusty. Pallas.

Inhabits Siberia, and is the size of the yellow-hammer.

**FERRUGINEA.** Ferruginous; belly, and two spots on the primary quill-feathers, white. Arct. Zool. *Rufy bunting*, Lath.

Native of North America.

**AMERICANA.** Above cinereous, streaked with brown; beneath yellow; chin white; quill and tail-feathers black, with pale edges. Gmel. *Black throated bunting*, Arct. Zool.

Found in New York. Size of the yellow-hammer. The female is like the male, but has no black spot on the throat, nor streak of yellow above the eye. Dr. Latham describes a variety met with in Hudson's bay, the colour of which is ashy brown, beneath whitish, front and eye-brows yellow; band under the eyes, and the crescent on the front, black; chin, as in the male of the other, with a triangular black spot in the middle.

**BRASILIENSIS.** Crown, neck, and body beneath, yellow; back, wings, and tail greenish, varied with yellow and brown. Gmel. *Guiram beemgata*, Ray. *Guirnegat*, Buff. *Brazilian bunting*, Lath.

Size of a sparrow. The species inhabits Brazil.

**MEXICANA.** Above brownish, beneath whitish, spotted with brown; head and throat yellow. Gmel. *Thérese jaune*, Buff. *Mexican bunting*.

Length six inches and a half; the legs and bill pale; wings and tail brownish. Native of New Spain.

**MILITARIS.** Head, wings, tail, and back brown; lower part of the back and breast yellow; shoulders greenish; belly white. Hasselq. *Military bunting*, Lath.

Inhabits Malta.

**MELANOCEPHALA.** Yellow, head black; back rufous. Scop. *Black-headed bunting*, Lath.

Size of the yellow-hammer, and inhabits Europe.

**BRUMALIS.** Body beneath; front and region of the eyes citron; hind head and neck cinereous. Scop.

Native of the Tyrolese country. This and the two following are small species.

**COCCINEA.** Body above silvery, beneath crimson; vent white; bill, head, and quill-feathers black; hind head and tail black-blue. Sander.

Found in the woods about Baden.

**BADENSIS.** Olive, striated with blackish, beneath paler; throat orange; breast with black streaks. Sander.

Inhabits Baden. The bill is black above, beneath yellowish, with a single obtuse tooth in the middle.

**ERYTHROPHALMA.** Black, with a red gloss; belly reddish; wings with a white spot. Gmel. *Fringilla Carolinensis*, Briss. *Towhee bird*, Catesby.

This species inhabits Carolina, frequents shady woods, and is generally seen in pairs. Called by some the American bulfinch. Length eight inches.

**LEUCOPHRYS.** Rusty brown, beneath white; vent yellow; crown black, with a white fillet in the middle; eye-brows white. Forst. *White crowned bunting*, Arct. Zool.

Inhabits Canada, feeds on grass, seeds, and worms, sings melodiously, and lays three or four chocolate-coloured eggs. Length rather exceeding seven inches.

**LUCTUOSA.** Black; beard on the chest, front, breast, belly, rump, and vent white. Scop. *Wreathed bunting*, Lath.

Size of the greater titmouse.

**AUREOLA.** Rufous, beneath yellow; transverse pectoral band ferruginous; crown, cheeks, and chin black. Pallas. *Emberiza Sibirica*, Lepechin. *Yellow breasted bunting*, Lath.

Size of the reed sparrow, and inhabits the pine groves of Siberia.

**SANDWICHENSIS.** Brown, beneath whitish, spotted with brown; eye-brows yellow; temples dusky. Gmel. *Unalaska bunting*, Arct. Zool. *Sandwich bunting*, Lath.

Length six inches; bill and legs black; under the eyes a dusky line; middle of the belly whitish and immaculate. Native of Sandwich bay.

**AONALASCHKENSIS.** Reddish brown; beneath whitish, streaked with brown; middle of the belly white. Gmel.

Length seven inches, inhabits Aonalaschka, and resembles the former.

**ATRICAPILLA.** Chestnut, beneath cinereous; chin white; crown pale yellow, front and streak through the eyes to the nape black. Gmel. *Black crowned bunting*, Lath.

Native of the Sandwich islands; its neck is seven inches, the bill black, and legs brown. A variety is described in Cook's last voyage, which has the breast waved with black; the female without the yellow spot on the crown.

**PITHYORNUS.** Middle of the crown with an oval white spot; nape varied with white; chin red-testaceous; two exterior tail-feathers, each side with an oblique white band. Pallas. *Emberiza leucocephala*, S. G. Gmelin. *Emberiza alia species*, Lepechin. *Pine bunting*, Lath.

Inhabits the pine forests of Siberia, from the Uralian chain of mountains to the Lena; it lives among reeds on the shores of rivers, and passes the winter sometimes on the borders of the Caspian sea. The size is that of the yellow-hammer, and it has the note of the reed sparrow.

**CINEREA.** Bay, beneath whitish, spotted with bay; tail and quill-feathers brown, edged with grey; rump grey; tail-coverts reddish white. Gmel. *Emberiza canadensis*, Briss. *Cul-rouffet*, Buff. *Cinereous bunting*, Arct. Zool.

Length five inches and a half, and inhabits the juniper woods in Canada.

**CERULEA.** Rufous and blue varied; crown rufous; greater

## EMBERIZA.

greater wing-coverts, quill-feathers, and tail-feathers, brown, with the outer edge rufous. Gmel. *Emberiza canadensis cerulea*, Briff. *Azuroux*, Buff. *Blue bunting*.

Inhabits Canada, and rarely New England. Its length is four inches and a half.

**CYANEA.** Blue; crown deeper; quill, and tail-feathers brown edged with blue. Lath. Ind. Orn. *Emberiza cyanea, redricibus fuscis*, Gmel. *Tanagra cyanea*, Linn. *Ministre*, Buff. *Blue linnet*, Catesby. *Indigo bunting*, Lath.

Size of the finch. The male, when in full plumage, is blue, at other times resembles the female, which is nearly throughout of a brownish colour; in the latter, however, the edge of the wing is tinged with green, and by this peculiarity the female may be distinguished from the male, the edge of his wing being blue. In Carolina, the inland parts of which this species inhabits, it is called the parson, and by some the bishop; and the Spaniards at Mexico, which country it inhabits, also name it azul lexos, or "far-fetched blue bird." It feeds on seeds, and is said to have the note of the common linnet.

**CYANELLA.** Shining blue-interfeathers and shoulders varied with blue and rufous; quill and tail-feathers edged with blueish. Sparrm. Mus. Carl. *Emberiza cyanella*, Gmel. *E. cyanea*,  $\beta$  Lath.

Described by Sparrman as a species. Gmelin admits it with doubt, and Latham considers it as a variety only of *cyanea*; it is a native of North America.

**QUELEA.** Grey; front black; bill scarlet. Gmel. *Moineau à bec rouge du Sénégal*, Buff. *Black faced bunting*, Lath.

The bill of this bird is thick; cheeks and chin black; rest of the head, shoulders, and back varied with black and grey; breast and belly reddish white; quill and tail-feathers blackish, edged with cinereous. The species inhabits Senegal, and is four inches and a half in length. The female resembles the male, but wants the black about the head. The bird described by Buffon, under the name of *Moineau du Senegal*, is considered as a variety.

**PETRIX.** Chestnut, beneath yellow; eye-brows and rump yellow; middle of the head and breast with a broad black band. Gmel. *Weaver bunting*, Lath.

Size of the house sparrow, which bird it resembles in the brownish colour of the plumage during winter. The name of weaver bunting was given to this bird from its propensity to interweave silk between the wires of its cage, like the weaver oriole, and, it is conjectured, the nest of the weaver bunting is composed in a manner somewhat similar to that of the above-mentioned oriole, which consists of leaves curiously sewed together with the filaments of plants. This bird inhabits Africa.

**RUBRA.** Crimson; neck and back varied with olive and black, and a few crimson marks; belly and vent cinereous; quill and tail feathers black, edged with grey-green. Gmel. *Moineau de l'île de France*, Buff. *Crimson bunting*, Lath.

Size of the last, and inhabits the île of France. The bill is black; legs pale flesh colour; female olive and paler beneath.

**CAPENSIS.** Grey; throat whitish; ocular band and another beneath blackish. *Hortulanus capitis lone sp. i.*, Buff. *Ortolan du Cap de Bonne Esperance*, Buff. *Cape bunting*, Lath.

Native of the Cape, and in size resembles the sparrow. Three varieties of this species are described in Buffon's

"Planches Enluminees," namely,  $\beta$ , the body of which is yellow beneath, and the sides of the head and neck marked with three black stripes;  $\gamma$ , having the body beneath whitish; and  $\delta$ , which is whitish beneath, and has the throat varied with cinereous. The two first of these are conceived to be merely varieties of the Cape kind, the last is a native of Cayenne, where, according to Buffon, it is called *Bonjour-commandeur*, from being accustomed to commence its song at the break of day.

**FUSCA.** Brownish; wings and tail brown with dusky bands; belly white; nostrils, cheeks, and chin with feathered tufts. Gmel. *Barred-tailed bunting*, Lath.

Described by Dr. Latham from a figure met with among some Chinese drawings. The size is said to be that of the common bunting. The beak is flesh-coloured; legs rosy.

**LUDOVICIA.** Rufous spotted with black; beneath pale; breast rufous; head with a black crescent. Gmel. *Hortulanus ludovicianus*, Briff. *Ortolan de la Louisiane*, Buff.

Length five inches and a quarter. The bill rufous spotted with black, head and throat reddish; rump and cuneated tail black; breast rufous; legs cinereous. Native of Louisiana.

**CIA.** Reddish; head with a few blackish lines; eye-brows white. *Emberiza barbata*, Scop. *Emberiza pratensis*, Gessn. *Bruant fou*, Buff. *Bruant de sprés*, Buff. *Foolish bunting*, Lath.

Native of the warmer parts of Europe, and delights most in mountainous situations; it is a silly bird, and easily caught in any snare, whence its name; its note is only a repetition of sounds, like the pronunciation of the words zi-zi-zi-zip-zip. The Genoese call it *Cia montanina*.

**CIRLUS.** Fuscous; breast spotted; eye-brows pale yellow; two outmost tail-feathers with a white cuneated spot. Gmel. *Emberiza sepiaria*, Briff. *Cirlus*, Aldr. *Cirl bunting*.

Size of the yellow-hammer, and inhabits Italy and France; the species has been lately found in Britain.

**FAMILIARIS.** Cinereous spotted with brown; tail-feathers white at the tip; hind part of the back yellow. Gmel. *Bruant familier*, Buff. *Familiar bunting*.

Osbeck describes this species under the name of *Motacilla familiaris*. This writer speaks of it as a docile bird, and says, if the cage-door was opened it would jump out upon the person's hand who released it, and if any one whistled in its hearing, it sang sweetly in return. If a dish of water was placed before it, the bird instantly plunged into it, and bathed itself. It was fed with rice.

**FLAVEOLA.** Grey; face yellow. Gmel. *Flaveole*, Buff. *Yellow-faced bunting*.

Native of warm climates, and very small.

**AMAZONIA.** Brown; crown fulvous; vent whitish. Gmel. *Amazone*, Buff. *Amazon bunting*.

Size of the titmouse, and inhabits Surinam.

**ORYZIVORA.** Black; crown reddish; belly black; tail-feather daggered. Gmel. *Agripenne ou Ortolan de riz*, Buff. *Rice bird*, Catesby. *Rice bunting*, Arct. Zool.

About the size of the sparrow. The species is confined to the continent of America, and is of the migratory kind, passing in flocks at particular seasons from one part to another. The Americans call it *Bob Lincoln* and *Conquedle*. Its food consists of grain and insects, and the maize especially; they are remarkably fond of this plant, and prove highly destructive to the crops, by unnecessarily perforating the husks after satisfying their appetites, and thus leaving openings

## EMBERIZA.

openings through which the rain penetrates, and effectually destroys the plants. Some, for this reason, call it the maize thief, or white backed maize thief. Its note is much admired. There is a variety of this bird of an olive-brown colour, beneath y flowish; rump yellow, transversely lined with brown; greater wing-coverts and quill-feathers edged with white.

**SCHOENICULUS.** Head black; body grey and black; outmost tail-feathers with a white wedged spot. Linn Fn. Succ. *Junco turneri*, Geln. Buff. *Reed bunting*, Lath.

Native of Europe and the southern parts of Siberia. The female differs from the male in having the head brownish instead of black.

**LESBIA.** Beneath white; face white with three black bands; breast and rump brownish; tail-feathers white, the two middle ones dusky, edged with rufous. Gmel. *Mitilene de Provence*, Buff. *Lesbian bunting*, Buff.

Length about four inches and a half; it inhabits Provence, where it is called Chic de Mitilene, being rare in that part, and known to be common in the Greek isle Mitilene, or Lesbos. They are said to exert a peculiar kind of scream on the approach of any bird of prey, a circumstance which the Greeks turn to some advantage, for they place one or more of these birds inclosed in strong iron cages in their poultry yards, and the approach of the hawk, or any other bird of prey, is loudly announced by these little centinels the moment it appears in sight; and by this means the poultry are allowed sufficient time to effect their escape.

**PROVINCIALIS.** Beneath white; band across the eyes and on the wing and chin white; spot under the eyes, streak each side the chin, and breast brownish spotted with black; quill and tail-feathers dusky, edged with rufous. Gmel. *Gavoué de Provence*, Buff. *Mustachoe bunting*, Lath.

Size of the last, and inhabits Provence.

**LOTHARINGICA.** Spotted with black; above rufous, beneath cinereous, abdomen rufous; streak across the eyes and on the mandibles black; tail-feathers black and white, middle ones rufous; exterior ones nearly all white. Gmel. *Ortolan de Lorraine*, Buff. *Lorrain bunting*.

Inhabits Lorrain; the female is white beneath, and has a whitish spot above and a rufous one beneath the eyes. Length six inches and a half.

**PSITTACEA.** Brownish-ash; wings tawny; two tail-feathers very long. Gmel. *Fringilla brasiliensis*, Seba. *Veuve éteinte*, Buff. *Psittaceous bunting*, Lath.

Size of a sparrow, and inhabits Brasil.

**PARADISEA.** Black; breast red; four middle tail-feathers long, and pointed; two very long, bill black. Scop. *Vidua*, Briss. *Indian long-tailed sparrow*, Will. - *Red-breasted long-tailed finch*, Edw. *Whidah bird*, Lath.

Native of Angola in Africa.

**SERENA.** Head black; crown red; tail cuneated; two middle tail-feathers very long; legs grey. Gmel. *Vidua minor*, Briss. *Veuve dominicaine*, Buff. *Dominican bunting*, Lath.

Like the rest of the long-tailed buntings, this bird is destitute of the two long tail-feathers during winter, and changes its plumage twice in the year.

**VIDUA.** Blackish; beneath whitish; four middle tail-feathers long and pointed, two of them very long; bill red. Gmel. *Vidua major*, Briss. *Grande veuve*, Buff. *Long-tailed sparrow with a scarlet bill*, Will.

The body of this species is less than that of the sparrow; the species inhabits Angola in Africa and India.

**PRINCIPALIS.** Variegated; breast rufous; four middle tail-feathers very long; bill and legs red. Gmel. *Vidua angolensis*, Briss. *Variegated bunting*, Lath.

Vol. XIII.

Inhabits Angola.

**REGIA.** Middle tail-feathers very long, equal, feathered only at the tip; bill red. Gmel. *Veuve à quatre brins*, Buff. *Shaft-tailed bunting*, Lath.

Inhabits the maritime parts of Africa. Length four inches and a half. The body above and vent black; throat, temples, orbits, and body beneath rufous; legs red.

**LONGICAUDA.** Black; shoulders orange, edged with white; tail-feathers long, the six middle ones very long. Gmel. *Veuve à épaulettes*, Buff. *Yellow-shouldered oriole*, Brown.

Native of the Cape of Good Hope.

**PANAYENSIS.** Black; breast with a large scarlet spot; four middle tail-feathers very long, pendulous, pointed and equal. Gmel. *Veuve en feu*, Buff. *Veuve de l'isle de Panay*, Sonnerat. *Panayan bunting*.

Inhabits the isle of Panay.

**ANGOLENSIS.** Black; crown and collar yellow; tail long. Gmel. *Gros-bec à poitrine couleur de feu*, Salerne. *Angola bunting*.

Size of a finch, and inhabits Angola.

**CIRIS.** Head blue; abdomen fulvous; back green; feathers green brown. Gmel. *Painted finch*, Catesby. *China bulfinch*, Albiu. *Painted bunting*, Arct. Zool.

Length five inches and a half, varies in colour, and inhabits South America; they build in the orange trees, and feed on plants of various kinds. In Holland, and some other parts of Europe to which they have been transported, they are reared in cages like the Canary with us, and are said to live eight or ten years in this state of captivity.

**QUADRICOLOR.** Head and neck blue; back, wings, and tail at the tip green; tail and abdomen in the middle red; breast and remainder of the belly brownish. Gmel. *Gros-beak de Java*, Buff. *Red rump bunting*, Lath.

Native of Java. Length five inches.

**CYANOPIS.** Green; wing and abdomen rufous; front, cheeks and chin blue; quill-feathers brown, edged with green; tail-feathers edged with red; middle ones green, the rest brown. Gmel. *Chloris javensis*, Briss. *Toupet bleu*, Buff. *Blue faced bunting*, Lath.

Length four inches; inhabits same country as the last.

**VRIDIS.** Above green; beneath white; wings and tail blue. Gmel. *Chloris indica minor*, Briss. *Parement bleu*, Buff. *Green bunting*, Lath.

Size of a sparrow; the bill greenish brown; shafts of the quill and tail-feathers white; and legs black. Native of India.

**PLATENSIS.** Above greenish-brown; beneath whitish-ash; back varied with black; quill, and lateral tail-feathers edged with yellow. Gmel. *Emberise à cinq couleurs*, Buff. *Plata bunting*, Lath.

Length eight inches. This species inhabits near the river Plata in South America.

**BORBONICA.** Rufous red; wings, tail, and legs chestnut. Gmel. *Mordoré*, Buff. *Bruant de l'isle de Bourbon*, Buff. *Bourbon bunting*.

Inhabits the isle of Bourbon.

**CALFAT.** Hoary; beneath vinaceous; head, chin, and edge of the tail black; bill and orbits rosy. Gmel. *Calfat*, Buff. *Red-eyed bunting*, Lath.

Less than the common sparrow, and inhabits the isle of France.

**CHLOROCEPHALA.** Fuscous; head and neck olive; back and wing-coverts varied with brown and black; tail forked. Gmel. *Green-headed bunting*. Brown's illustr.

A very ambiguous kind; probably an accidental variety of some European bunting. The bird described was caught

in Mary-le-bone fields, and preserved in the Tunstall Collection.

**GRISEA.** Grey; wing-coverts and breast varied with red; quill and tail-feathers within white, without varied with grey and red. Gmel. *Emberiza Surinamensis*, Briss. *Gonambouch*, Seba. *Grey bunting*, Lath.

Inhabits Surinam, where it is common, and its note is said to be equal to that of the nightingale. Its food is chiefly maize. The natives call it gonambucho.

**SURINAMENSIS.** Grey, beneath pale-yellow; breast with oblong black spots. Gmel. *Prayer*, Fermin. *Surinam bunting*, Lath.

Rather larger than the lark. Inhabits Surinam.

**RUFICAPILLA.** Body above fuscous, beneath cinereous; chin ferruginous; frontlet white; above reddish; tail black. Sparm. Mus. Carl.

**ASIATICA.** Cinereous; wings and tail brown. Lath. Ind. Orn. *Gaur bunting*.

Inhabits the East Indies, where it is known by the name of gaur.

**EMBLEM**, *ἔμβλημα*, a kind of painted ænigma, which, representing some obvious history, with reflections underneath, instructs us in some moral truth, or other matter of knowledge.

The word is pure Greek, formed of the verb *εμβαλλειν*, to cast in, to insert. Suetonius relates, that Tiberius caused the word to be erased out of a decree of the Roman senate, because it was borrowed from another language.

Such is that very significant image of Scævola, holding his hand in the fire; with the words, "agere & pati fortia, Romanum est;" "to do and suffer courageously is Roman."

The emblem is somewhat plainer, and more obvious, than the *ænigma*; which see. Gale defines emblem an ingenious picture, representing one thing to the eye, and another to the understanding.

The Greeks also frequently gave the name emblems, *εμβληματα*, to inlaid or mosaic works, and even to all kinds of ornaments of vases, moveables, garments, &c. And the Latins used *emblemata* in the same sense. Accordingly, Cicero, reproaching Verres with the statues and fine wrought works he had plundered from the Sicilians, calls the ornaments fixed thereto (and which, on occasion, might be separated from them) *emblemata*. Add, that Latin authors frequently compare the figures and ornaments of discourse to these *emblemata*: thus, an ancient Latin poet, praising an orator, says, that all his words were ranged like the pieces in mosaics,

" Ut tessellæ omnes,  
Arte pavimenti, atque emblemate vermiculata."

We do not use the English word emblem in this sense; though the ancient juriconsulti always retain the Latin *emblemata* to express such ornaments; because the Greek *εμβλημα* literally denotes any thing applied, or added to a body by way of enrichment.

With us, emblem ordinarily signifies no more than a painting, basso relievo, or other representation, intended to hold forth some moral or political instruction.

What distinguishes an emblem from a device is, that the words of an emblem have a full, complete sense of themselves; nay, all the sense and signification which they have together with the figure. But there is yet a farther difference between emblem and device; for a device is a symbol appropriated to some particular person, or that expresses something which concerns him particularly; whereas an emblem is a symbol that regards all the world alike.

These differences will be more apparent from comparing the emblem above quoted with the device of a candle lighted; and the words, "juvando confumor," "I waste myself in doing good." See **DEVICE**.

According to lord Bacon, emblems are of use in the art of memory, as sensible objects strike the mind stronger than what is intellectual. Thus, it is easier to retain the image of a sportsman hunting a hare, of an apothecary ranging his boxes, an orator making a speech, a boy repeating verses, or a player acting his part, than the corresponding notions of invention, disposition, elocution, memory, and action. Works abr. vol. i. p. 136. vol. ii. p. 475. and vol. iii. p. 106.

**EMBLEMS, Hagiographical.** The statues and pictures of the apostles, martyrs, and other ancient saints, are distinguished by their respective emblems. These appear to have been fixed upon by the artists of the 12th and 13th centuries. Sometimes they represent the instruments of their death or torments, as the Burgundy cross of St. Andrew, the gridiron of St. Laurence, the cardine comb of St. Blase, the wheel of St. Catharine; at other-times they relate to some circumstances in the life or legend of the saint, as the organ of St. Cecily, the dove of St. Gregory the Great; frequently they bear allusion to the name of the holy personage, as the lamb of St. Agnes, the gigantic stature of St. Christopher, bearing the infant Christ upon his shoulders.

**EMBLEMATICAL CHARACTERS.** See **CHARACTER**.

**EMBLEMENTS, Fr. from *emblaver*, q. d. *semer en blé***, to sow with wheat, a term strictly signifying the profits of lands sown; though sometimes used more largely for any profits arising, and growing naturally from the ground; as grass, fruit, &c.

If a tenant for life sow the land, and die before harvest, his representatives shall have the emblements to compensate for the labour and expence of tilling, manuring, and sowing the lands, and also for the encouragement of husbandry; and not he in reversion. But if the tenant for years sow the land, and before severance the term expires, or the estate for life be determined by the tenant's own act, as by forfeiture for waste committed, or if a tenant during widowhood thinks proper to marry, there the lessor, or he in reversion, shall have the emblements, and not the lessee.

The advantages of emblements are particularly extended to the parochial clergy by 28 Hen. VIII. cap. 11.

All the cases of emblements turn upon the point of uncertainty; since the tenant could not possibly know when his landlord would determine his will, and therefore could make no provision against it; and having sown the land, which is for the good of the public, upon a reasonable presumption, the law will not suffer him to be a loser by it. But it is otherwise, and upon reason equally good, where the tenant himself determines the will; for in this case, the landlord shall have the profits of the land. (Co. Litt. 55, 56.) These emblements are distinct from the real estate in the land, and are subject to many, though not all, the incidents attending personal chattels. They were devisable by testament before the statute of wills (Perk. § 412.); and at the death of the owner, shall vest in his executor, and not his heir; they are forfeitable by outlawry in a personal action (Bro. Abr. tit. emblements, 21. 5 Rep. 116.); and by the statute 11 Geo. II. c. 19. though not by common law (1 Roll. Abr. 666.), they may be distrained for rent arrear. Although the emblements are assets in the hands of the executor, are forfeitable upon outlawry, and distrainable for rent, they are not in other respects considered

sidered as personal chattels; and particularly, they are not the object of larciny, before they are severed from the ground. (3 Inst. 109.)

**EMBLICA**, in *Botany*, Gærtn. t. 108. f. 2. See **PHYLLANTHUS** and **MYROBALANUS**.

**EMBODY**, in the *Military Art*. To *disembody*, relates to the separation of those individuals forming a regiment, &c. when its services are no longer required. This term is totally divested of that disgrace which is conveyed under the terms *dismissed*, or *broken*. Thus we find, that, during times of danger, the militia are called out; and on the return of peace, that orders are issued for their being "disembodied." Hence, in that admirable satire, "the Mayor of Garrat," major Sturgeon says, "Our corps is disembodied, so the French may sleep in security."

When a regiment is disembodied, or, in other words, disbanded, (though the latter term is often, but erroneously, intended to convey reproach,) the arms are lodged in the proper store-rooms; and every thing is numbered or ticketed; in order that when the regiment may again be called out, all may be in readiness for its equipment.

**EMBOLE**, in *Surgery*, the reduction or setting of a dislocated bone. The term is derived from the Greek *εμβολη*, to put in.

**EMBOLI**, in *Geography*, a town of European Turkey, in the province of Romania, a colony from Athens. It is called by the Christians "Christopolis," but is little better than a heap of ruins; 48 miles E. of Saloniki.

**EMBOLIMA**, in *Ancient Geography*, a town of India, on this side of the Ganges. It was situated S.W. of Petra Aornos, upon the right of the Indus, and N. of Taxila.

**EMBOLIMÆAN** and **EMBOLISMIC**, *Intercalary*, is chiefly used in speaking of the additional months which chronologists insert to form the lunar cycle of 19 years.

The 19 solar years, consisting of 6939 days, and 18 hours; and the 19 lunar years only making 6726 days; it was found necessary, in order to render the 19 lunar years equal to the 19 solar, which make the lunar cycle of 19 years, to intercalate or insert 7 lunar months, containing 209 days; which, with the 4 bissextile days happening in that interval, make 213 days, and the whole, 6939 days. See **CYCLE**.

By means of these seven embolismic, or additional months, the whole 6939 days and 18 hours of the solar years are employed in the calendar.

In the course of 19 years there are 228 common moons, and 7 embolismic moons. Their distribution is thus: every 3d, 6th, 9th, 11th, 14th, 17th, and 19th, years, are embolismic, and consequently contain 384 days a-piece. And this was the method of computing time among the Greeks, when they used the enneadæcteries, or cycle of 19 years. But they did not keep regularly to it, as the Jews seem to have done. The Greeks were followed by the Romans till the time of Julius Cæsar.

The embolismic months, like other lunar months, are sometimes 30 days, and sometimes only 29. See **YEAR**.

The embolismic epacts are those between XIX and XXIX; which are thus called, because, with the addition of the epact XI, they exceed the number XXX: or rather, because the years, which have these epacts, are embolismic; having 13 moons a-piece, whereof the 13th is the embolismic.

**EMBOLISMUS**, *εμβολισμος*, in *Chronology*, signifies intercalation.

The word is formed of *εμβαλλω*, to insert. See **EMBOLISMIC**.

As the Greeks made use of the lunar year, which is only

354 days, in order to bring it to the solar, which is 365 days, they had every two or three years an embolism, i. e. they added a thirteenth lunar month every two or three years; which additional month they called embolimus, *εμβολιμυς*, because inserted, or intercalated.

**EMBOLUS**, the immovable part of a pump, or syringe; called also the *pisson*, and popularly the *sucker*. See **PISTON**, **PUMP**, and **SYRINGE**.

The pipe, or barrel of a syringe, &c. being close shut, the embolus cannot be drawn up without a very considerable force; which force being removed, the embolus returns again with violence. This phenomenon the Aristotelians attribute to nature's abhorrence of a vacuum.

But the modern philosophers finding, that in an exhausted receiver the embolus is easily drawn up, though the orifice be stopped, prove that it is the pressure of the atmosphere on the external parts of the embolus, that makes the difficulty of drawing it up. See **AIR**, **ATMOSPHERE**, and **SUCTION**.

**EMBORDERED**, in *Heraldry*, a term applied to a border, when it is of the same metal, colour, or fur, with the arms.

**EMBORISMA**, an aneurism.

**EMBOSSING**, or **IMBOSSING**, the act of forming, or fashioning works in relief, whether they be cast, or moulded, or cut with the chissel, &c.

Embossing is one great part of sculpture; being that which has to do with figures raised, or prominent from the plain, or ground; the other part, which makes figures, &c. that are indented, or cut in below the ground, is called engraving. See **ENCHASING**.

**EMBOSSING**, or *Imbossing*, in *Architecture*, is that kind of sculpture wherein the figure is made to stand in relief beyond a plane or naked from which it seems to rise. It has three denominations, according to the degree with which it rises from the surface, as basso-relievo, mezo-relievo, alto-relievo; or low-relief, mean-relief, high-relief.

**EMBOTHRIUM**, in *Botany, so named by Forster from *ev*, *in*, and *βοθριον*, a little pit, or hollow, alluding to a small cavity towards the point of each petal, in which the almost sessile anthers are severally placed. Forst. Gen. 8. t. 8. Linn. fil. Suppl. 16. Schreb. 62. Willd. Sp. Pl. v. 1. 537. Juss. 79. Mart. Mill. Dict. v. 2. Sm. Bot. of N. Holl. 19—29. t. 7—10. Class and order, *Tetrandria Monogynia*. Nat. Ord. *Proteacea*.*

Gen. Ch. *Cal.* none. *Cor.* Petals four, cohering by their lower part into a tube, linear, oblique, at length revolute; their summits dilated, concave, bearing the stamens. *Stam.* Filaments four, very short, inserted into the hollow in the tip of each petal; anthers rather large, kidney, or heart-shaped. *Pist.* Germen superior, stalked, linear, ascending, inflexed; style incurved; stigma large, obtuse, lateral. *Per.* Follicle stalked, somewhat cylindrical. *Seeds* in two rows, imbricated, compressed, each with a membranous wing, generally numerous.

Ess. Ch. Petals four. Stamens inserted into the limb. Follicle containing several winged seeds.

This is a fine genus of the Proteaceous order, chiefly found in New Holland. One of the two original species, indeed, *E. coccineum*, Linn. Suppl. 128. Cav. Ic. v. 1. 47. t. 65, grows on the cold hills bordering the straits of Magellan, even in Terra del Fuego. Yet this appears by Commerson's and Forster's specimens to be a very handsome shrub, with all the air of a North American *Kalmia* or *Rhododendron*. The leaves are elliptical and entire, smooth, pale beneath. Flowers scarlet, in a dense terminal-cluster,

with small linear *bractæas*. *Follicle* short, and rather semi-ovate.

*E. speciosissimum*, Sm. Bot. of New Holland 19, t. 7, is a still finer species, a native of New South Wales, where the natives call it Waratâh. Living plants were sent many years ago to the dowager lady de Clifford. This is remarkable for the numerous large scarlet *bractæas*, which envelop its dense spike of the same colour. The *leaves* are obovate and serrated, remarkably obtuse.

*E. flajfolium*, Sm. Bot. of N. Holland, 23, t. 8. flowered at Mr. Grimwood's nursery, Kensington, in 1792, being forced in the stove. It comes also from New South Wales, and has finely divided rigid *leaves*, with loose spikes of white *flowers*.

*E. fericum*, *ibid.* 25, t. 9, and some of its varieties are now not rare in the greenhouses about London. See Curt. Mag. t. 862, and Andr. Repof. t. 100 and t. 272.

Mr. R. Brown, in paper on *Proteacea*, read last winter before the Linnæan Society, has new-modelled and greatly subdivided the genus *Embohrizium*, he having had opportunities of studying its species alive in their native situations, which no other botanist has so fully enjoyed.

EMBOUCHURE, a French term in *Music*, literally the hole in the upper joint of a German flute, in which the performer breathes; but when it is said that a flute player has a good embouchure, it means that his tone is good.

EMBOUL, in *Geography*, a town of Africa, in the country of Senegal.

EMBOWELLING ALIVE, in *Law*, is part of the punishment of high treason.

EMBRACE a VOLT, in the *Manege*, is used when a horse, in working upon volts, makes a good way every time with his fore legs. The opposite term to embracing a volt, is beating the dust, which is putting his fore-feet near the place from whence he lifted them.

Embracing the ground is used in the same sense with embracing the volt. A horse cannot take in too much ground provided his croupe does not throw out; that is, does not go out of the volt. See BEAT.

EMBRACEOR, in *Law*, a person who, when a matter is in trial between party and party, comes to the bar with one of the parties (having received some reward so to do), and speaks in the cause, or privately labours the jury, or stands there to overlook, awe, or put them in fear; or, who makes any attempt to influence a jury corruptly to one side by promises, persuasions, intreaties, money, entertainments, and the like. (1 Hawk. P. C. 259.) The punishment for the person embracing is by fine and imprisonment; and for the juror so embraced, if it be by taking money, the punishment is (by divers statutes of the reign of Edward III.) perpetual infamy, imprisonment for a year, and forfeiture of the tenfold value.

EMBACERY, the act or offence of embraceors. See EMBRACOR.

EMBRASURE, in *Architecture*, an enlargement of the gap or aperture of a door, or window, within-side the wall. See DOOR.

Its use is to give the greater play, for the opening of the door, wicket, casement, &c. or to take in the more light.

The embrasure coming sloping inwards, makes the inner angles obtuse. When the wall is very thick, they sometimes make embrasures on the outside.

EMBRASURE, in *Fortification*, is an opening made through the upper part of the defences, called the *parapet*, for the purpose of pointing the cannon, so as to be as little as possible exposed to the fire of the enemy. The embrasure must

vary in dimensions with the several sizes, or, as they are technically termed, the "natures" of the cannon to be employed in them respectively. It is, however, generally found, that about  $2\frac{1}{2}$  diameters of the muzzle of the cannon intended to be mounted give space enough for traversing, and at the same time afford but little opening for the shot from opposing batteries. The embrasure must be cut down in that proportion which may suit the height of the carriages on which the cannon may be mounted: thus, for all under 24 pounders, the height, between the front of the platform, and the crest, *i. e.* the interior, or highest part of the slope, over which the cannon is levelled, ought not to exceed 28 inches, unless the trucks on which the carriages run are unusually high; for all cannon of 24 pounds calibre, and upward, the space above described, and which is called the *genouillere*, ought to be from 34 to 40 inches. The best rule is, to allow eight inches between the crest of the slope and the under part of the cannon, when horizontally laid, thereby to command freedom of action, even when the depression of the line of fire may be considerable: were this not attended to, the cannon might, at such times, be levelled after each discharge, before it could be run up to the *genouillere*; whereby considerable delay would be created. The slope, by which we mean that part under the muzzle of the cannon, is ordinarily made with a descent of about ten or twelve degrees from the crest outwards, to allow of depression, so as to fire either into the ditch, or over the glacis; this slope must necessarily vary according to the situation, and intention of the battery. Thus, in some situations it is found necessary even to invert the slope, the cannon being always pointed above the horizon: this occasionally happens in erecting batteries while besieging a place, where it would be both useless and disadvantageous to cut the embrasures any lower than the lowest direction to which the cannon should be pointed. On the other hand, we sometimes see the slopes made at full forty degrees of depression, in consequence of the battery being intended to command some work, of approach, far below its own level. But, as before observed, when works are constructed upon an ordinary *defilement*, (or branching out,) originating from a level at the exterior of the *glacis*, and proceeding without any increase of elevation to the centre of the place, then from 10 to 12 degrees of depression in the slope will be fully adequate to all the purposes of depression of the cannon. The expansion of an embrasure, that is, its becoming wider exteriorly, than it is interiorly, must depend on circumstances; but we generally find their sides to diverge at an angle of about 12 or 15 degrees from a line passing through the centre of the slope, in a direction with the chace of the cannon when brought up square to the *genouillere*. It should, perhaps, seem proper to make the embrasure spread as widely as possible, for the purpose of including a greater extent of direction; but were such to be practised, the *merlon*, *i. e.* the body of parapet left between any two embrasures, would be so considerably diminished as to afford little protection from the enemy's shot, which would, at the same time, gain admission, obliquely, into the battery, and dismount the cannon by a plunging fire. On the other hand, it is absolutely necessary to give such an expansion as may not only allow the reasonable traversing of the cannon, thereby to cover a greater extent of the approaches, but to prevent the *merlons* from being destroyed by the fire of their own cannon, of which the explosion would speedily bring down the revetements, whether of masonry or of turf, unless ample space were allowed for the concussion of the air created by the discharge to be sufficiently weakened. We have heard of defences that were destroyed rather by the

want of this consideration, than from the enemy's fire. Where the *merlons* are of solid masonry, and consequently the thickness of the parapet inconsiderable, when compared with that attendant upon *merlons* made of soil, there may be allowed rather more contraction than in the latter case, because the explosion is not confined for such a distance. Few cases, however, can occur, in which the divergence of the sides can come under ten, or exceed fifteen degrees. Where it is not advisable to keep all the intended embrasures open, or where deception is an object, they are either left unfinished, the parapet being left entire, or their fronts are filled up with the same materials as the front of the parapet. The former is common in situations where the soil is loose, and the difficulty of sustaining the merlons considerable. When embrasures are cut through such parapets, their sides must be sustained by *fuscines*, as in the case of field batteries, and approaches during a siege. The latter description, *i.e.* the concealed embrasures, form what is called a masked battery, which generally opens by surprise; the first discharge generally serving to clear away the slight work built up for the purpose of concealing the situations of the cannon. Where it is absolutely necessary that cannon should be allowed to traverse freely in various directions, such, for instance, as sea-lines, where every gun should be made to follow a ship passing with a rapid tide, and likewise in block-houses mounting heavy ordnance on their roofs, no embrasures should be made; but the cannon should be mounted on carriages traversing on pivots, and elevated above the body of the ramparts, which may nevertheless be made high enough to cover the defenders very completely. Cannon mounted in this manner command a great range of direction, and, though not so well secured from being dismounted as when placed in embrasures, are pre-eminently serviceable in some situations. Batteries of this description are called *barbet batteries*, and should, with little exception, be invariably preferred, wherever they are not liable to be opposed by cannon, or where the force to be acted upon is expected to pass with velocity, without being able to take a settled aim at the *barbet*. Mortar batteries have no embrasures, they requiring only a given line of direction, aided by due elevation, to effect their object; and, as both may be given without seeing it, the parapets of such batteries are left entire. What are called embrasures on board bomb-ketches, are nothing more than temporary openings made by unshipping hatches, and by fitting stout planks at the sides to confine the sparks from spreading within the vessel. In casemates, especially those in the *curtain*, &c. the embrasures are made like the port-holes in a ship; that is, nearly square, and allowing the muzzles of the cannon to pass completely through.

**EMBREGMA**, an embrocation. The term is derived from *εμβρεχω*, to make wet.

**EMBROCATION**, or rather **EMBROCHATION**, *Embrocha*, *Εμβροχη*, formed from *βρεχω*, *irrigo*, I sprinkle, or moisten, in Pharmacy, denotes the application of remedies, as oils, spirits, decoctions, and other liquids, by sprinkling, or even rubbing them on the part affected: this is also called irrigation.

Embrocations are only a kind of lotions; they are used to remove obstructions, and to relieve pains, numbness, and palsies. The pumping used in natural baths is properly an embrocation.

**EMBROCATION**, *gall*. See **GALL**.

**EMBROIDERY**, the enriching of a cloth, stuff, or muslin, by working diverse figures thereon with the needle, and thread of gold or silver.

The word embroidery is derived from the French

*broderie*, of *broder*, to embroider; which some deduce, by transposition, from *bordeur*, because they formerly embroidered only the borders of stuffs, whence the Latins also call the embroiderers *limbularii*. Du-Cange observes, that they anciently wrote *aurobrustus* for embroidered with gold, or *brustus brudatus*, and *brodatus*; whence *broderie*.

That done with silk, flax, or the like, is not now called embroidery; though anciently, and properly, the word denoted all kind of figuring or flourishing.

The chief use of embroidery is in church vestments, cloaths, housings, guidons, standards, &c. The invention of embroidery is attributed to the Phrygians; whence the Latins call embroidered garments "*vestes Phrygionia*," and embroiderers *Phrygiones*. In the "*Menæchmi*" of Plautus, (act ii. scene 3), a young woman, desirous of sending her mantle to be embroidered, says: "*Pallam illam ad phrygionem ut deferas, ut reconcinatur atque ut opera addatur, quæ volo.*" The Greeks seem to have used the words *αεβισυ* and *αοβισυ*, as we use the word embroider.

The embroidery of stuffs is performed in a kind of loom; that of muslin is done by stretching it on a pattern already designed; the former kind is the most easy, but the latter admits of the greatest richness and variety. The thinnest muslins are the best for this purpose; and they are embroidered to great perfection in Saxony.

There are diverse kinds of embroidery; as *embroidery on both sides*, that which appears on both sides. *Guimped embroidery*, performed either in gold or silver. In this work, a sketch is first made on the cloth, then they put on a cut vellum, and afterwards sew on the gold and silver with silk thread, interspersing silver and gold cord, tinsel, and spangles. *Embroidery on the stamp*, where the figures are very high and prominent, being supported on wool, cotton, hair, &c. *Low and plain embroidery*, where the figures are low and flat, and without any enrichment between them. It is probable that the covering of the sword of Goliath, which was laid up in the tabernacle as a consecrated memorial of the victory gained by David over that vain-glorious idolater, or the wrapper that enveloped it, was some beautiful piece of embroidered work. (1 Sam. xxi. 9.) By statute 22 Geo. II. c. 36. no foreign embroidery, or gold or silver brocade, shall be imported, upon pain of being forfeited and burnt, and penalty of 100*l.* for each piece. No person shall sell or expose to sale any foreign embroidery, gold or silver thread, lace, fringe, brocade, or make up the same into any garment, upon pain of having it forfeited and burnt, and penalty of 100*l.* All such embroidery, &c. found, may be seized and burnt, and the mercer, &c. in whose custody it was found shall forfeit 100*l.*

**EMBRUN**, or **AMBRUN**, in *Geography*, a town of France, in the department of the Upper Alps; chief place of a district of the same name, situated upon a high rock on the right shore of the river Durance, 66 miles S.W. of Grenoble, and 480 miles S. by E. of Paris, is chiefly remarkable for its cathedral, and has a population of 3138 individuals. The canton contains 8 communes and 9667 inhabitants, on a territorial extent of 285 kilometres.

As chief place of a district Embrun has a sub-prefect, two courts of justice, and a register office. The whole district is extremely mountainous, but the vallies and the declivities of the mountains are uncommonly fertile. It contains five cantons, 36 communes, and 26,968 inhabitants, on a territorial extent of 1472½ kilometres.

**EMBRYO**, or **EMBRYON**, in *Anatomy* and *Physiology*, is the child, with its coverings, as contained in the uterus previously to the time of birth. It is supposed at first to be in an imperfect state, but to contain rudiments of all the parts,

parts, which, when fully developed, make up a perfect animal. The term is derived from the Greek word *ἐμβρυον*, which has the same signification, and is formed from *ἐν, in*, and *έρω, I shoot out*; conveying a notion, that the living germ buds forth and expands in the uterus of the mother, as a seed is developed in the earth. The term embryo is employed, in its most strict acceptation, during the first six weeks only after conception, but it is often used more generally during the whole time of utero gestation. The young animal, after the first six weeks, is called a *fœtus*; but we use this word also to denote the same object as soon as it can be distinctly perceived. By the *ovum*, we understand the *fœtus*, together with its surrounding membranes; but that term is sometimes applied to the latter only, in contradistinction to the former. We shall consider, under the present article, the progress of the uterine contents, until the time of utero-gestation is completed; the changes, which they pass through, in the different stages of this period; the peculiarities of structure belonging to the *fœtus*; and the mode of its nutrition and existence.

A sketch of the progress of the germ, after impregnation, from the ovarium into the uterus, and of its development in the latter cavity, will be found in the article CONCEPTION; a more detailed history of the anatomy of the ovary and uterus, together with a statement of all the facts that can be ascertained concerning the mode of impregnation, and its immediate consequences, will be contained under the head of GENERATION.

When the germ is detached from the ovarium, the mode of its existence differs in the different classes of the animal kingdom. In the greatest number of instances it is accompanied by an organized mass, to which it adheres by means of vessels, and the absorption of which is sufficient to nourish and develop it, until it is brought forth into the world. It requires no supply therefore from the body of the mother; and is even separated from her by more or less numerous and solid coverings. The germ, together with the nutritious substance, and the common envelopes, constitute an *egg*, and the animals which propagate their species in this way, are called *oviparous*. In many of these, the germ contained in the egg is not developed and hatched, until the egg has quitted the body of the mother, or has been *laid*; in which case fecundation may be performed afterwards, as in many fishes, or external heat only may be required, as in the incubation of birds: or, lastly, the natural temperature of the climate may suffice, as in reptiles and insects. All these are *oviparous* animals, properly so called. In some others, the egg, after having been fecundated, and detached from the ovary, remains in the mother's body, until the young one is developed and hatched, as in the viper, and in several fishes: such are falsely *viviparous*, or *ovo-viviparous* animals. Mammalia only are truly *viviparous*; their germ is provided with no supply of aliment, but derives the materials of its growth from the juices of the mother. For this purpose it is attached to the internal surface of the uterus, and occasionally, by accident, to some other part, by a kind of root; by an infinite ramification of blood-vessels, constituting the *placenta*. Instead, therefore, of being separated by its coverings from the body of the mother, these are the medium of a most intimate connection between them, essentially necessary to the life of the germ. Through them there is a constant influx of nutritious juices until the embryo is completely developed. At that time the membranes are torn, and the young animal comes into the world, capable of enjoying an independent organic existence, and free from all external covering. The very rare occurrence, of the child being born with its membranes

entire, cannot be regarded as an exception to this assertion: Wrisberg only saw it three times in 2000 births; (see his *Observat. de Structurâ ovi*, p. 76.) and it is probably still less common on the average. In the mammalia then there is no *egg*, in the sense already explained: the membranes of their *ovum* being an intimate connection between the mother and the germ, by which the former supplies the latter with nourishment; while the *egg* is entirely detached, and contains, with the germ, the nourishment necessary for its growth. Hence we see, that the old and much-contested maxim of "omnia ab ovo," cannot be received without great limitation, and is more likely to perplex, by confounding together things essentially different, than to impart any additional light to a subject already very obscure.

The following parts, which are of course contained in the cavity of the pregnant uterus, make up the human *ovum*; viz. the *placenta*, *membranes*, *navel-string*, *liquor amnii*, and *fœtus*. The three first are called also the *secundines* or *after-birth*; as they are expelled, in the act of parturition, after the child. The *placenta* and *membranes* every where line the cavity of the uterus, and the former must undoubtedly have some communication with the vessels of the mother, although anatomists have not yet succeeded in demonstrating the precise mode of that connection. In the membranous bag formed by the *secundines*, there is found, besides the *fœtus*, a greater or smaller quantity of clear fluid, called the *liquor amnii*. The umbilical chord contains blood-vessels, by which the circulating organs of the *fœtus* communicate with the arteries and veins of the *placenta*.

The *secundines* are all more or less gelatinous and transparent, and contain no manifest fibrous structure. Being destroyed after every pregnancy, their existence is temporary; and their organization corresponds to this limited term of duration. They never contain any fat, either in the sound, or in the morbid state of parts, at any period of utero-gestation, however the mother or child may be circumstanced in this respect.

The cavity of the uterus, examined immediately after conception, exhibits nothing which can be regarded as the fruits of that process. In a few days, we perceive a transparent membranous vesicle, filled with a gelatinous liquor, but offering no appearance of organization or life. Some writers have asserted that ova may be found in the uterus of the human subject, or of animals, immediately after conception; and have even published delineations of them in the first days of pregnancy. Such statements deserve no credit. Those modern physiologists, in whom we can place the greatest confidence, have found, during the first seventeen days, nothing but a fluid like white of egg, in which there was no trace of any more consistent body. Mr. Cruikshank, however, has met with ova in the tubes and uteri of rabbits, at a much earlier period. He found them in the former situation on the third day after coition: they were mere points, but the distinction of the chorion and amnios could be discerned by the aid of magnifying powers. The *fœtus* was rendered visible on the eighth day, by pouring vinegar on the *ovum*. We may regard all observations in which an *ovum* is said to have been discovered in the human subject, earlier than the twentieth day, as extremely suspicious: indeed, we know of no instance, in which it has been observed, before this time, by any person whose testimony has sufficient authority. A round little body is gradually developed in the cavity of the uterus, and may be recognized at the end of the third week. This is the covering of the future, but not yet discernible *fœtus*. The surface of such an *ovum* is probably flocculent from the first; this at least is the case in the smallest hitherto delineated,

delineated, and in well preserved specimens of very small and early abortions. The flocculi are very fine vascular ramifications, connecting the ovum to the decidua, which resembles in appearance a layer of coagulable lymph produced by inflammation. The resemblance of these villi to the roots of a plant, the mode of their insertion in the decidua, and the analogy of their function, in draining from the uterus and conveying to the child, the materials of its support, to the office which roots perform, in extracting nourishment from the soil, has led almost every writer to compare the rudiment of the future animal to a seed, and to consider its connection with the mother's body as similar to that between a plant and the earth. The vascular processes are small in very young ova, but enlarge afterwards rapidly till the second month: they gradually disappear from two-thirds of the surface of the ovum, and are collected together on the remainder, to be united into a mass, and form the placenta.

It has not been hitherto determined at what period the ovum becomes connected to the uterus; indeed it is so small, at its first arrival in the cavity, that the investigation is difficult. Cruikshank says, that the ovum increases in the rabbit, to one hundred times its original size, before it becomes fixed to the uterus. The size of the ovum, at different periods of pregnancy, cannot be determined with much accuracy, because many abortions are not well formed, and their exact age cannot be well ascertained. Hence different writers contradict each other considerably in this point. Within the first month it is not larger than a hazel nut; in the second and third it may equal a pigeon's or hen's egg. At the latter period its development is complete, and the future changes are chiefly in size. It increases in proportion to the augmentation of the uterus.

*Particular description of the component parts of the ovum.*—The membranous covering including the fœtus, within the uterus, consists of several distinct parts, which admit easily of artificial separation. The number of these has been very variously represented. The older anatomists only describe two; *viz.*, the chorion and amnios; and divide the former into two laminæ. Most moderns describe three coverings, adding the decidua of Hunter to the two former. Haller mentions four;—the *membrana exterior ovi*, chorion, *membrana media*, and amnios. Blumenbach's division into the proper, and adventitious coverings is a good one: the latter are the chorion and amnios; the former, the decidua, which covers the ovum and lines the uterus.

The *decidua*, or *membrana caduca*, is the medium of connection between the embryo and the mother. In its appearance, as well as in its mode of formation, it resembles the lamina of coagulating lymph, which is formed by inflamed surfaces. Both membranes are of a yellowish white colour; both are tender, pulpy, and vascular. The lamina of lymph is formed by an inflamed membrane; the uterus, before the appearance of the decidua, becomes much more vascular, and is probably in a state of increased action analogous to inflammation. The development of this membrane is probably anterior to the arrival of the germ in the uterus, and may be regarded as a measure of preparation for its reception. It is not necessary for the formation of the decidua, that the ovum should reach the uterus. For when it grows in the ovary, or in the Fallopian tube, the decidua is formed in the uterus, and that organ is considerably enlarged; so that it undergoes, to a certain degree, changes exactly similar to those which take place in natural pregnancy. It lines the whole internal surface of the uterus, being perforated at the Fallopian tubes, and cervix uteri. Numerous small arteries and veins, often seen containing red blood, ramify from its outer surface inwards

through its substance, and are derived from the vessels of the uterus. It is very thin, and has no perceptible vessels near the cervix uteri; but grows thicker and more vascular towards the placenta, at the very edge of which it acquires a considerable thickness, and splitting into two strata, is continued over both surfaces of the placenta, but especially the inner smooth surface, blending itself there inseparably with the umbilical portion of the placenta. The layer of the decidua, which lies between the chorion and placenta, is in one case much thicker than in another. It sometimes forms a smooth, tender, opaque membrane; but is more frequently reticulated, especially towards the edge of the placenta, looking somewhat like lace. Occasionally there are portions of it a good deal thicker than the rest; which, shining through the transparent chorion, bear some resemblance to pieces of fat. This layer is generally thicker than that which adheres to the rough, external, lobulated surface of the placenta. It communicates with that other, by means of the processes of the decidua, which pass between the lobules of the placenta, and along the external surface of the umbilical vessels.

We have already observed, that the decidua adheres closely, on its external surface, to the uterus, and that this adhesion is effected by means of blood-vessels passing to the former from the latter. By its means the whole external surface of the ovum grows to the uterus. Its internal surface is very closely attached to the chorion, so that their separation is difficult in recent secundines. Gentle putrefaction makes them part easily; and we observe, on the separation, numerous white slender threads, emerging from the substance of the chorion, and ramifying into smaller filaments upon the decidua. These appear like vessels by the aid of a magnifying glass.

As this membrane is an adventitious production of the internal surface of the uterus, formed for the temporary purpose of a connecting medium between the mother and the child; its office ceases as soon as the fœtus has quitted its original situation; and it is consequently shed whenever a woman bears a child, or suffers a miscarriage. Hence its names of *decidua* and *caduca*. As it may be partially separated into two strata, one of these is left on the uterus after delivery, and afterwards dissolves, and comes away with the lochia. Frequently a thicker stratum separates from the uterus in one part, and a thinner in another. The adhesion of the decidua to the uterus and chorion is stronger than that of the two layers of the membrane to each other; and hence, probably, we may explain the circumstance of a stratum being left upon the uterus after parturition. The best method of seeing the decidua after labour, is to wash the secundines well in warm water, to remove the loose coagulated blood, and then put them into cold water, that the blood, which remains in the vessels, may congeal. The decidua will then be very distinguishable by its yellowish appearance and pulpy consistence; and numerous vessels may be clearly discerned in its substance. The number and size of the vessels, passing from the uterus to the decidua, sufficiently account for the bleeding which always takes place on the separation. These vessels are represented as filled with blood in Hunter's 29th plate, fig. 4: and in their injected state in several other figures of the same work; *viz.* the arteries in fig. 3, tab. 24; the veins in tab. 24, fig. 4: and both kinds of vessels coming from the uterus, in tab. 31. The second fig. of tab. 29. of the same work, exhibits the reticulated lace-like appearance of the membrane, when viewed with magnifying powers: in this respect it much resembles the adventitious productions of coagulating lymph.

The preceding description applies to the decidua, as it is found

found in ova of seven, eight, or nine months. The membrane is very different in the earlier periods; and as the descriptions of anatomists have been derived chiefly from abortions, in which more or less of the decidua may come away with the ovum, and as the appearance of the membrane differs very much in the different periods, the accounts of it are very perplexed, and difficult to understand. The thickness of the membrane is in an inverse ratio to the age of the embryo. In an early state, too, its external surface is covered with numerous loose and floating flocculi, by which it adheres to the surface of the uterus; these are not seen at more advanced periods: they are excellently represented in an abortion of the seventh week, in two beautiful figures, forming the vignette of the title page of Soemmerring's *Icones Embryonum Humanorum*: also in Hunter, figs. 1, and 2. pl. 33.

From the time that the ovum has acquired some size, until about the fourth month, the decidua not only lines the whole cavity of the uterus, but also gives another covering to that part of the chorion, which is not occupied by the placenta. This second investment is continuous with the former at the edge of the placenta; and, as it appears at this part as if reflected from the exterior layer over the ovum, Dr. Hunter, to whom we are indebted for the most accurate observations on the whole subject, called it *decidua reflexa*; the addition of Hunter is often made by foreign anatomists. He compares, in the explanation of pl. 33, fig. 1, the reflection of the decidua over the ovum, to that of the pericardium over the heart; and the comparison might be correct, if the exterior portion of the pericardium covered the whole of the heart, as the outer layer of decidua does the whole ovum. According, then, to the preceding description, we may distinguish three portions of decidua, all, however, completely connected together; 1st. The exterior portion, covering the whole ovum, and lining the whole uterus, excepting the apertures corresponding to the Fallopian tubes and cervix; *decidua uteri*, *d. vera*, *membrana ovi exterior* of Haller, *membrana caduca crassa* of Mayer (Beschreib. des menschlichen Körpers, v. 5. s. 272.) because it is thicker than the reflected portion, first membrane of the ovum of Mekel, *decidua externa* of Sandifort, and external lamella of the Hunterian decidua of some authors. 2dly. A production over the concave surface of the placenta. 3dly. *D. reflexa*, covering the chorion, and continuous at the margin of the placenta, with the *D. uteri*. This is Blumenbach's acquired membrane, Mekel's second membrane, *villosa membrana placentæ*, *involucrum membranaceum* of Albinus, *membrana filamentosa* of Wrisberg and Roderer, chorion of Haller, chorion fungosum, flocculentum, &c., spongy chorion, reflected vascular membrane, &c. Denman calls it connecting membrane, and Baillie *decidua chorii*. A cavity must necessarily be intercepted between this and the *d. uteri*. The distinction of these two parts, and their relative position, are best seen in the plates of Hunter; as in fig. 1, of tab. 28: also in a perpendicular section of the uterus, containing an ovum of three months, represented in tab. 32, where the letters *k, l, m, n, o*, represent the two deciduæ, the angle of reflection, and the cavity left between them. The same facts are also represented in two abortions, figs. 1, 2, 3, and 4, of tab. 33. The *d. reflexa* covers the shaggy vessels of the chorion, which seem to be implanted in it. In proportion as pregnancy advances, it becomes gradually thinner and thinner, so that at the fourth month it forms an extremely fine layer covering the chorion. It comes at the same time into more close contact with the *d. uteri*, and, at length, the two adhere together. Yet the membrane

diminishes in thickness, and continues to decrease until parturition. How it comes to pass, that the decidua should envelope the ovum in the way already described, is mere matter of supposition, and does not admit of being shewn by direct demonstration. In two examinations, mentioned by Dr. Baillie as having been performed with great care at an early period of pregnancy, the decidua was already formed, but no ovum could be discovered.

In the 18th fig. of his work already quoted, Soemmerring has given an excellent view of the external surface of an ovum of five months. It appears on close inspection covered with fine and thinly scattered flocculi, which are the most numerous and long in the situation of the placenta. The first, or external coat, (the decidua,) is continued into the placenta, or the placenta is extenuated into this membrane, in such a way, that we might, with equal propriety, either regard the placenta as the thickest portion of the decidua, or the decidua as an extenuated production from the placenta. The decidua grows gradually thinner as we recede from the placenta, so that its thinnest portion is precisely opposite to the placenta.

The *chorion* is that covering of the ovum which is placed next in order to the decidua. It is the first proper membrane of Blumenbach, the third membrane of Mekel, and the second of many anatomists; the *membrana media* of Haller, chorion pellucidum or leve.

It is a firm and strong membrane, forming a complete bag, which includes the amnios and child. It adheres firmly to the concave surface of the placenta, and in that situation is thicker, and covers the great divisions of the umbilical vessels; being closely attached to the amnios at the insertion of the umbilical chord. At first it is nearly transparent, and tender in its texture: as the ovum increases, it becomes more opaque, stronger, and of a yellowish colour. We have mentioned already how its external surface adheres to the decidua, and the threads connecting them together, which seem to be vessels. These are the only vessels which the membrane possesses.

The external surface of the chorion is covered completely with flocculi in the first month of pregnancy. A great abundance of thin tender threads of different thickness arise from it. These divide and subdivide in a very minute manner, and the neighbouring ramifications join each other. They are extremely small on very young ova; but they cover the whole surface at the end of the first, and in the second month. They disappear from some parts in the third month; and collect closer together towards the upper part of the ovum, in order to form the placenta.

The decidua reflexa, covering this external surface of the chorion, unites the flocculi together; which penetrate it, and are implanted in the decidua uteri. Many erroneous names and representations have arisen from this structure, because the processes of the chorion have been regarded as belonging to the *d. reflexa*; and hence many of the names applied to that membrane have arisen.

In the fourth, fifth, and sixth months the chorion is smooth on the greatest part of its external surface. The *d. reflexa*, which is now thin and scarcely recognizable, is close upon it. When the placenta is formed, the external surface of the chorion is firmly attached to its concavity.

The internal surface of the chorion is smooth, and united to the amnios: In the first month there is a considerable interval between the two membranes, filled with a clear aqueous fluid, probably produced by the vessels of the chorion: this space is soon diminished; the amnios growing faster than the chorion, the two membranes soon come in contact.

contact. In the third month they lie near together, and are loosely connected by a tender gelatinous medium.

Twins have a double chorion, as well as amnios; but are covered by a common decidua reflexa.

*Amnios*; the second proper membrane of Blumenbach; and fourth membrane of Haller and Meckel; is found universally in animals. In man it forms an oval bag, including a certain portion of fluid, and the fœtus. It is a thin transparent membrane, of tolerably firm consistence. Its external surface is connected, in the way already described, with the chorion, from which it is easily separable. It lines the concave surface of the placenta, and terminates, apparently, by a close adhesion at the insertion of the navel-string, where the chorion also seems to end. The gelatinous substance connecting the two membranes adheres more closely to the amnios than to the chorion, and hence the former membrane has a rough appearance, when separated. The internal surface is every where perfectly smooth. In birds and quadrupeds it possesses manifest vessels; but none in the human subject.

The allantois, which was formerly enumerated among the membranes of the human ovum, is now known to be peculiar to quadrupeds.

There is, however, a small membranous bag, named *vesicula umbilicalis*, found in the early months of pregnancy between the amnios and chorion. This possesses an elliptical figure, and contains a clear fluid. It contracts into a thin and round thread, which runs along the navel-string, and divides into two at the insertion of the umbilical chord in the child's body. They are afterwards lost upon the viscera. This vesicula can only be seen until the third month, and in very fresh abortions; for it is so delicate that it decays very quickly; and it is extremely difficult to trace the thread from it through the umbilical chord. Its size is in an inverse ratio to the age of the embryo.

*Liquor amnii* is the name given to the fluid which fills the cavity of that membrane. This is perceivable as soon as the ovum can be discerned; it distends the membranes, and preserves their rounded form. Its quantity is the largest, in proportion to the size of the embryo, in the first month of pregnancy; so that in the first and second it considerably exceeds the weight of the fœtus, which must consequently be loosely suspended in the fluid. The fœtus weighs more in the third month than the liquor amnii; and, as it touches the membranes in the fifth, the proportional quantity of the water has very greatly decreased; so that it merely filled up the intervals caused by the inequalities of the child's body. Stein, an experienced German writer, states that the weight of the fœtus and the amniotic fluid should be equal about the middle of pregnancy; and that it must be regarded as an unnatural appearance, if the latter exceeds the former in the sixth month. It continues afterwards constantly decreasing relatively to the increase of the child. The quantity varies greatly in different subjects; from one to two pounds is the ordinary proportion at the period of nine months; but it may be much more or less. It is a clear yellowish fluid; but sometimes differently coloured and obscure. In its pure state it possesses no smell, and a mild saltish taste. Heat and alcohol coagulate it in the recent state; but the chief bulk of it is aqueous. The sources of the secretion are unknown. The absurd opinions, by which it has been supposed to proceed from the skin or various other parts of the fœtus, are sufficiently refuted by the fact of its existence when there is no fœtus. The amnios possesses no apparent vessels. For an account of the chemical properties of this fluid, see the article AMNIOS.

The old opinion of the use of the amniotic fluid in nourish-

ing the fœtus cannot be sustained; for deglutition could not be performed without the presence of air; many fœtuses are born with the mouth closely shut, and others have grown to the full size without any mouth at all. The great use of the fluid seems to be that of protecting the fœtus from external violence; and hence we find it most copious when the child is youngest and most delicate in texture, to prevent its different parts from adhering together, or to the surrounding membranes. The business of parturition, as far at least as the dilatation of the os uteri is concerned, is also facilitated by the liquor amnii.

The *umbilical chord, funis or funiculus umbilicalis*, or navel-string, made up of three large vessels twisted together, united by more or less gelatinous substance, and constituting, in consequence of certain convolutions of the vessels, an irregular rope, rather less in general than the size of the little finger, is fixed at one end to the child's navel, and at the other to the placenta. This being the organ of communication, through which the materials of growth and nourishment are derived to the fœtus from the mother, constitutes a most essential part of the secundines, and can never be deficient. It passes through the liquor amnii, from the child to the rest of the secundines; is commonly about two feet long, but may be no more than one foot, or on the contrary exceed four feet. Wrisberg once saw it only seven inches long; and it was necessary to cut it in the course of the delivery. Its most frequent length is between 18 and 22 inches. The younger the fœtus, the shorter is the chord proportionally. It is also thicker relatively to the size of the fœtus, as that is younger. It is usually turned round some part of the child's body; very commonly round the neck, which it has been seen to encircle four times and a half.

From the important function performed by the navel-string, we shall expect to find it as soon as the embryo itself is perceptible; and consequently it is seen as soon as the fœtus itself is visible.

The vessels of the chord are two umbilical arteries, and one umbilical vein. The two arteries are of equal size, and possess strong coats, so that their section presents a circular area. In rare instances there is only one. The umbilical arteries are a continuation of the internal iliacs; which, instead of descending into the pelvis, ascend along the side of the bladder to the umbilicus. When there is only one umbilical artery, the internal iliac of one side only is reflected along the bladder. The internal iliac, which in the adult is no larger, but rather smaller than the external, is considerably the largest of the two in the fœtus. It passes obliquely from the side of the pelvis to that of the bladder, and takes the name of umbilical or hypogastric; crossing the ureter in such a manner that that tube lies internally, and the artery externally. It ascends along the side to the fundus of the bladder, and proceeds over the surface of the peritoneum, to the umbilicus. These vessels make very numerous convolutions and turnings which differ considerably in different subjects; and hence they are much longer than the length of the chord. In the situation of these turns, the diameter of the vessels will appear contracted, and these contractions are the *quasi-valvule* of Hoboken.

The third vessel of the chord is the umbilical vein, which arises from the placenta, forms numerous convolutions, in company with the arteries, and enters the child's body at the umbilicus. Passing over the surface of the peritoneum, it arrives at the suspensory ligament of the liver; descends along its anterior margin to the fossa, dividing the two lobes; and there enters the substance of the liver. It distributes several branches to this viscus, particularly to its

left lobe, and ends by an anastomosis of its trunk, with the left branch of the vena portarum. From the vessel formed by this union a small canal, about three quarters of an inch in length, is continued into the inferior vena cava, under the name of *ductus venosus*.

The umbilical vein is much larger than the artery, and its sides collapse when divided. It is said that two veins have been seen; but Dr. Hunter never met with a case; quadrupeds have two. The umbilical vessels give off no visible branches till they come to the placenta; then the two arteries anastomose, commonly by a cross canal, nearly of the size of one of the arteries.

"There is a great variety," says Dr. Hunter, "in the twisting of the vessels of the navel-string. Sometimes they are uniformly and closely twisted like a rope, in their whole course; and sometimes they run almost straight and parallel, especially in that part of the string which is towards the placenta; for near the fœtus it is almost always more or less twisted. In some navel-strings there is a great irregularity, from solitary turnings of particular vessels, commonly called knots, as we see in twisting a cord, where some of the constituent threads are longer and therefore looser than others. The end of the navel-string which is next the placenta, is always less twisted, and more uniform than the end which is next the fœtus.

"Whatever be the cause, in most which I have attended to, the twisting of the navel-string has been in the same direction, *viz.* such as would be produced in turning the child round upon the navel, as a centre, by pushing its head towards the right side, and its feet to the left. In two and thirty preparations now before me, four only are twisted the contrary way; and of the twenty-eight which are twisted in the common way, three have the contrary twist for some inches, at the extremity, which was towards the fœtus." The vessels appear to be straight in young embryos. When the chord is very long, true knots are formed in it; as distinguished from those which arise merely from projections of particular vessels. These are not supposed in general to affect the communication between the mother and child, but Dr. Hunter thinks he has seen two cases in which it was obstructed from this cause. The true knots are sometimes double, as if twice tied; and in very rare cases treble.

The *urachus* is another part belonging to the umbilical chord; it is a small fibrous string ascending from the fundus of the bladder to the navel, between the umbilical arteries, and growing more slender as it proceeds. In the navel-string it is hardly perceptible, except near the fœtus; it is like a fine thread, a little more white and opaque than the rest. When once found near the fœtus, it may be traced, with a little trouble, nearly the whole length of the string. This part is a canal in the embryo of animals, leading from the bladder to the allantois; but the latter membrane not existing in the human subject, the urachus is solid. Portal, who has investigated the matter very attentively, found the urachus to consist of four threads in embryos of five and six months. These pass together from the navel to the bladder; then separate and expand over the latter organ. In the eighth and ninth month, these threads can hardly be separated. The urachus altogether is largest in the youngest embryos.

The covering of the navel-string, which is smooth and polished, is considered to arise from a reflection of the amnios. Both that membrane and the chorion are firmly adherent to the chord, at its connection with the placenta; and the covering of the chord itself is most firmly connected with the subjacent substance, so that it cannot be separated like a distinct membrane. The integuments of the abdomen

are continued for a short space over the chord, and there is an abrupt line observed at their termination, beyond which not even the cuticle is continued. The separation is much more strongly marked, when the integuments are minutely injected, by the sudden ending of the injection, no vessel extending into the chord. The tying of the chord without the least pain is a sufficient proof that it has nothing to do with the skin.

The strong connection between the abdomen of the child, and the chord, is produced by the three umbilical vessels, penetrating the tendinous opening of the linea alba. They run externally to the peritoneum, which lies behind them entire and unperforated. The opposite end of the funis is connected with equal strength to the placenta, both by the continuation of the vessels into that body, and by the close adhesion of the chorion and amnios.

Besides the vessels, the urachus, and the coat of the navel-string, it contains nothing but a fine cellular substance, loaded with a transparentropy fluid, giving the part both firmness and bulk. By touching the cut surface of the fresh funis, and removing the finger slowly, we see the fluid so tenacious and ductile, as to be drawn out into fine threads some inches in length. When it has been kept some days, the fluid loses entirely that glutinous quality, and transudes like water; by which means the string loses much of its bulk. In this state, if a small blowpipe be pushed into the interstices of the vessels, and proper ligatures be made, the whole interstitial substance may be rendered emphysematous and white. In this condition it may be dried, and then cut up to shew the cellular substance more distinctly. The great variety that is observed in the thickness or size of the navel-string in different parts, and in different cases, depends principally on the quantity of the cellular substance, and not on the bulk of the child.

Dr. Hunter thinks that "the winding course of the vessels in the navel-string prevents their being much affected by any stretching force, and the firmness of the interstitial substance, protects them against dangerous compression. These accidents might otherwise perhaps have occasioned frequent mischief, especially where there is a large child, and a small quantity of the liquor amnii. In such a case the navel-string passing under the arm or ham, or in the groin, might have been compressed, so as to prevent the return of the venous blood at least. The same thing might have easily happened, where a knot is formed upon the navel-string."

The umbilical arteries divide in the placenta into smaller and smaller ramifications; and their ultimate branches communicate with the umbilical veins; injected fluids at least return very readily by this course. The vein is made up by the union of the minute branches into larger and larger trunks. In the early periods of pregnancy, the umbilical vessels branching out very minutely, constitute the flocculi of the chorion.

*Placenta.*—This, together with the membranes, makes a complete bag lining the uterus, and containing the child. As Dr. Hunter has done much in elucidating its structure, and has given a very good account of the subject, we shall avail ourselves chiefly of his labours.

Its figure is commonly round and flat; it is about an inch in thickness and a span in breadth. It grows gradually thinner towards the edge, so as to render the change from the placenta to the membranes more imperceptible. When the cellular part is well filled with wax, or any fluid, it is at least two inches thick. Its shape is often oblong or triangular, or irregular; and sometimes there is a small lobe or two entirely distinct from the rest. The outer surface, which adheres

adheres to the womb, and is therefore naturally convex, is rough, tender in its substance, commonly covered with blood, lightly subdivided into smaller constituent lobes, and, to a common observer, apparently possessing no blood-vessels, or at least none of any considerable size. The internal surface, naturally more or less concave, is glossy, hard or compact in its texture, and beautifully marked with the ramifications of the umbilical vessels. The navel-string, which produces these branching vessels, is inserted sometimes into the very centre, but more commonly a little nearer the edge, and often into the very edge of the placenta. In four different instances, Dr. Hunter saw the navel-string terminate on the inside of the membranes, at the distance of five or six inches from the placenta. In all these cases the umbilical vessels parted from one another even to considerable distances in their course upon the membranes, and came to the edge and inner surface of the placenta at different places, even at the opposite parts. The termination or insertion of the navel-string, wherever it happens to be, makes the centre of ramification for the large vessels on the internal surface of the placenta.

The human placenta, like that of quadrupeds, is a composition of two parts intimately blended, *viz.* an umbilical or infantile, and an uterine portion. The former is made up by the ramification of the umbilical vessels of the fœtus; the other is a certain portion of the decidua, produced, as we have already described, from the surface of the uterus. The umbilical portion of the placenta is made by a regular ramification of the arteries and veins of the navel-string into smaller and smaller branches, without any lateral anastomosis, so that when unravelled by gentle putrefaction, motion, and washing, this part takes on the appearance of a tree whose branches divide to almost infinite minuteness, not only towards its outer surface, but every where through its substance.

The two umbilical arteries anastomose freely by a canal of communication just where they are going to branch out upon the placenta, so that by injecting one of them, the other is readily filled also. Every branch of an artery is attended with a branch of a vein; these cling to one another, and frequently, in the substance of the placenta, entwine round one another as in the navel-string.

Injections prove, both in the human subjects and in quadrupeds, that the umbilical arteries terminate in the veins of the same name, and not in the vessels of the uterus; and that the blood passes from the arteries into the veins, as in other parts, and so back to the child again. If the placenta be whole in all its substance, which is seldom the case, and its blood-vessels be pretty well emptied of their blood, any subtile injection thrown into an artery will fill the arterial system through the whole substance of the part to an amazing degree of minuteness, and return so freely by the veins as to fill them very generally and equally. In the same manner the whole umbilical system may be filled by injecting the vein, the fluid returning from the veins into the arteries. In both these experiments the injected fluid is confined to the umbilical vascular system, none escaping at the external surface of the placenta, neither by large nor small orifices, whether of veins or arteries.

When a placenta is finely injected, and then steeped, and frequently washed in clear water, it is evident that the umbilical vessels do not reach even the outer surface of the placenta, but are only seen through a membrane (decidua,) which covers all that surface. It is rough or ragged, like the inner surface of the uterus, to which it adheres, and by its whiteness becomes very distinct from the vascular injected part of the placenta, over which it is spread. It becomes still more distinguishable when the part is put into spirits,

which render it more opaque and whiter. This membrane is an efflorescence or production of the inner membrane of the uterus, and is analogous to the uterine fungi of quadrupeds. It receives no vessels, demonstrable by the finest injections, from those of the navel-string, yet it is full of both large and small arteries and veins. These are all branches of the uterine vessels, and are readily filled by injecting the arteries and veins of the uterus; and they all break through in separating the placenta from the uterus, leaving corresponding orifices on the two parted surfaces.

This decidua, or uterine portion of the placenta, is not a simple thin membrane expanded over the surface of the part, it produces a thousand irregular processes which pervade the substance of the placenta, as deep as the chorion or inner surface; and are every where so blended and entangled with the ramifications of the umbilical system, that no anatomist will perhaps be able to discover the nature of their union. While these two parts are combined, the placenta makes a pretty firm mass; no part of it is loose or floating. But when they are carefully separated, the umbilical system is evidently nothing but loose floating ramifications of the umbilical vessels, like that vascular portion of the chorion which makes part of the placenta in a calf; and the uterine part is seen shooting out into innumerable floating processes and rugæ, with the most irregular and most minutely subdivided cavities between them that can be conceived. This part answers to the uterine fungus of the quadrupeds. In a placenta at nine months the two constituent parts can only be separated by some degree of putrefaction, and gentle rubbing and washing; but this operation always destroys the uterine portion, which is more tender, and yields to putrefaction sooner than the other. In the placenta of an earlier age, the union of the two constituent portions is less intimate, and they may both be preserved very entire, like the vascular chorion and fungus of the quadruped. Dr. Hunter separated them in a conception of four months, and left the uterine portion attached to the inside of the uterus.

The two portions of the placenta are so interwoven with each other as to leave innumerable small vacuities, with free communications, through the whole substance. If this cellular structure be inflated or injected, the placenta, like the corpora cavernosa penis, acquires a very considerable increase of thickness, and subsides again when the fluid escapes. This cellular receptacle in the placenta cannot be completely filled after it has been parted from the uterus, because then the fluid, which we may by any contrivance throw in, will be discharged at innumerable orifices on the outer surface of the placenta; but while it remains attached to the uterus, all the cells may be easily and completely filled by injecting any fluid into the arteries or veins of the uterus. These vessels, and these only, have a demonstrable communication with the spongy cells of the placenta, which receive the maternal blood from the arteries of the uterus, and give it back into the veins of that part. Both these vessels pass in the decidua, and the larger branches of both, with little or no ramification, terminate abruptly in the cells. The arteries are all much convoluted and serpentine; the larger, when injected, are almost of the size of crow-quills. The veins have frequent anastomoses, pass in a very slanting direction, and generally appear flattened; some of them are at least as big as a goose-quill, and many of them are very small. They are very numerous round the edge of the placenta, and many run for a little way, in the direction of tangents to the circle, in the very angle between the membranes and the placenta.

In separating the latter part from the uterus, which can be

## EMBRYO.

effected with very slight force, all these vessels are necessarily torn through; and then each broken vessel has an open mouth on the inner surface of the uterus, and a corresponding orifice on the outer surface of the placenta. They may be readily observed on a fresh placenta, as soon as it has come away in a common labour. Air blown into the cellular part by thrusting in the end of a blow-pipe, rushes out readily by the open mouths both of the arteries and veins.

While the placenta remains adhering to the uterus, injection will pass either from the uterine arteries or veins into the cells of that organ; and, after filling these cells, it returns by the opposite order of vessels to that by which it was thrown in. Hence, if we wish to inject both systems in the gravid uterus, we should fill the first only moderately, and then the other.

The venous system of the decidua and uterus may be filled with air from the cells of the placenta. Introduce a blunt probe through a slit in the coat of the navel-string, and force it into the cells of the adjacent part of the placenta; then, withdrawing the probe, insinuate an injecting pipe, and tie it firmly with a broad thread round the navel-string. By that pipe you may fill the whole placenta uniformly in its cellular part, and likewise all the venous system of the uterus and decidua, as readily and fully as if you had fixed the pipe in the spermatic or hypogastric vein; so ready a passage is there reciprocally between the cells of the placenta, and the uterine vessels. It is as much reciprocal, and more largely open, than between the corpus spongiosum and the veins of the penis.

From all his experiments, repeatedly and diligently made, Dr. Hunter concludes, that the human placenta, like that of the quadruped, is composed of two distinct parts, though blended together, *viz.* an umbilical, which may be considered as a part of the fœtus, and an uterine, which belongs to the mother; that each of those parts has its peculiar system of arteries and veins, and its peculiar circulation, receiving blood by its arteries, and returning it by its veins; that the circulation through these two parts of the placenta differs in the following manner; in the umbilical portion the arteries terminate in the veins by a continuity of canal, whereas in the uterine portion there are intermediate cells, into which the arteries terminate, and from which the veins begin. Though the placenta be completely filled with any injection thrown into the uterine vessels, none of the wax finds its way into any of the umbilical vessels; and in the same manner fluids injected into the umbilical vessels can never be pushed into the uterine, except by rupture or transfusion.

Several views of the arteries and veins, which pass from the uterus to the placenta, are exhibited in Dr. Hunter's plates; see Tab. 15. fig. 1. Tab. 19. Tab. 29. fig. 1. and Tab. 30. and the same vessels on the surface of the uterus in fig. 3. Tab. 10. and fig. 2. Tab. 28.

It has been stated already, that the human placenta is made of a single mass; but some varieties have been observed in this respect. It possesses sometimes a small appendix; or it may be made up of three or more small pieces, united by means of the chorion. Wrisberg saw a placenta composed of seven pieces. Where there are twins, or three children, the placenta is usually single; but there may be two or three separate ones united by the amnios, which forms the partition of the bags containing the children.

*The Fœtus.*—The proportions of parts, and consequently the whole figure of the fœtus, differ very much before birth, from that which they possess afterwards; and they differ also very considerably at different periods of utero-gestation. Influenced by their opinions of the beauty and

due proportions belonging to the human frame in later stages of existence, many have called the fœtus, in its early periods, shapeless and destitute of symmetry; not reflecting that a different figure and relation of parts belongs, in the order of nature, to the age we are speaking of, and that this may still be beautiful and symmetrical according to the standard of that age. While the rose is still inclosed in the calyx, its appearance is very different from that which it exhibits when the petals burst forth from their confinement, and the whole flower is displayed in its mature and perfect state: yet we do not deem the rose bud inelegant or imperfect in its form. We may affirm, on the same principles, that every age in the human subject is distinguished by its peculiar kind of beauty; that the embryo, the fœtus, the infant, the youth, &c. possess their respective proportions, those of each differing from the others; and consequently, that an embryo may, with propriety, be termed beautiful, if its formation correspond to the standard of its age. It is true, indeed, that the fœtus in abortions is often ill-formed, being smaller than it should be, deviating from the usual proportions, or monstrous; and, very probably, this mal-formation may be one of the causes why such embryos die, and are separated with the ovum from the uterus; just as we see that mis-shapen or worm-eaten fruits seldom arrive at maturity, but have their further growth impeded by that very cause. To the same purport it is observed by Autenrieth, § 8, "that he found three monstrous fœtuses, out of nineteen, whose parts could be distinguished; that Wrisberg met with two among five, which he examined; and Ruysch two in twelve; the proportion of the whole being seven in twenty-nine. This large number, (if we consider, at the same time, that all the collections of anatomical preparations abound with monstrous fœtuses, which have died immediately after birth, while adult monsters are extremely rare,) renders it very probable that nature employs the short, but effectual means of extirpation, in order to preserve the genuine figure of the human frame, and that one model only, of all those into which the human frame may pass, is endued with permanent vital powers." This author observes also, that a greater number of abortive embryos are of the male than of the female sex; and this observation is confirmed by Soemmering, who extends it likewise to monsters.

It is extremely difficult to ascertain at what exact time the fœtus of an ovum becomes visible; because it is almost always impossible, in the human subject, to ascertain the date of the impregnation. Dr. Baillie states, that he saw a preparation in the possession of Dr. Combe, where, from peculiar circumstances, it had been ascertained that the conception was twenty-two days old, and where the fœtus was visible, although extremely small. In an abortion, which came away after the first cessation of the catamenia, dissected by Blumenbach, and exhibited in the 4th table of his "*Institutiones Physiologicæ*," the amnios was about the size of a large pea, but no vestige of the fœtus could be discerned.

The following account of the successive developement of the embryo is derived chiefly from Soemmering's work, "*Icones Embryonum Humanorum*," which is chiefly devoted to this subject, and exhibits a most beautiful series of embryos from the earliest period to the fifth month.

Generally speaking, the embryo grows the most rapidly in the first weeks after conception; the rate of its progress afterwards diminishes to the ninth month: this growth, however, does not proceed uniformly at all times. It is gradually retarded in the second month, accelerated in the third; stopped again in the beginning of the fourth, and

continued

continued more rapidly from the middle of that month to the sixth; from which time it is again retarded till the period of maturity. A similar observation has been made concerning the chief viscus of the embryo, by Walter, the son. (Annot. Acad. de hepate, § 8.) He found that the rapid and prodigious growth of the liver did not continue beyond the end of the fourth month. It appears, moreover, that different parts of the body of the embryo grow very differently; and that some arrive at a certain degree of perfection sooner than others.

The younger the embryo, the larger is the containing ovum. That part, therefore, in proportion to the fœtus, is the largest, most capacious, thickest, and firmest, in the earliest periods after conception; and the smallest, thinnest, and most tender, at the complete term of utero-gestation. At the middle of pregnancy it exhibits an intermediate state between these extremes.

In the first and second months the embryo is completely bent; a little straightened in the following month, and afterwards, as the limbs increase, convoluted into a kind of oval shape. The head is brought forwards on the chest during the whole period of utero-gestation. The younger the embryo, the greater is the bulk of the head, compared to that of the trunk; or, what is equivalent, the trunk is smallest at that time. The head must consequently be the largest when it can be first distinguished. In the first month the head considerably exceeds the size of the rest of the body. Its growth goes on less rapidly after this time, and does not exceed that of the trunk; so that at the age of five months, it bears a moderate proportion to the body. The younger the embryo, the smaller is the face, in comparison to the cranium. The pyramidal proportions of the temporal bones are particularly large in the first month.

The neck, corresponding in some degree to the size of the head, is large and short; so short, indeed, that it can hardly be recognized at all in the first and second months, being marked by the slightest constriction. It is scarcely distinguishable before the third month, on account of the head being bent forwards.

The extremities are smallest, in proportion to the trunk, in the youngest embryo. They first shoot out from the trunk in the form of hemispherical tubercles, like buds from a tree; are protruded a little further, and elongated in the second month; at which time, the upper limbs may be distinguished into arms and hands, and the lower into legs and feet. Then the fingers arise, like little papillæ from the hands; the arms and fore-arms being more developed; at the same time thighs, legs, and feet, may be distinguished in the lower limbs, but the latter are still without toes. These, however, shoot out at the end of the second month, the fingers being at the same time elongated. In the three first months the upper limbs exceed the size of the lower ones; they become nearly equal in the fourth; and in the fifth the lower ones have acquired that superiority which they afterwards retain.

The lower part of the spine is at first curved round towards the belly, so as to resemble somewhat the tail of a quadruped, when thrown between the hind legs. This prominence, sometimes called *tuber coccygeum*, is largest in the two first months, projecting beyond the lower limb, so as to give the spine a keel-like form. It gradually disappears in the third month, as the lower limbs are elongated.

The eyes are first observed, of the organs of sense, and are larger and more prominent as the embryo is younger. They are seen very distinctly in a beautiful and, as it should seem, perfectly formed fœtus of the first month, not larger than a middle sized pea, represented by Soemmerring. They

may always be recognized, in the very youngest embryos, by a deep black circle. Before the second month either the eye-lids are open, or so thin, that the black pigment of the bulb is discerned through them. Soemmerring thinks that the eye-lids are really open until about the tenth week, when they are closed. After that time he has always found them firmly shut, and the slit between them shorter than the diameter of the globe. The circle of the iris, which is of the deepest black, is completed sooner on the outer than the inner side.

Very small pores are seen in the situation of the external ears about the seventh or eighth week; the middle of the helix then rises from the head, and is followed successively by the tragus, antihelix, antitragus, lobulus, and upper part of the helix. The ears are completed by the formation of the concha and scapha in the fifth month. Their proportions are still very different from those of the adult. Two small holes at first occupy the situation of the nose, which itself gradually shoots out about the seventh week; the dorsum, alæ and septum are distinguishable in the eleventh week. The mouth is largest in the first months; and is open, without any lips. The latter parts are distinctly formed about the eleventh week, and are firmly approximated, so as to close the mouth, from the third month.

The genital organs, scarcely distinguishable in the first weeks, have acquired a considerable size at the commencement of the third month. The penis is large and prominent about the twelfth week, and the glans uncovered; the scrotum is small and empty until the 9th month. Sometimes it is loose, and distended with water; sometimes corrugated. A small slit is sometimes discerned in the female in the second month. The clitoris is large and prominent in the third month, like the corresponding organ of the male; so that a female embryo, viewed laterally, might be mistaken for one of the other sex. About the fourth month the clitoris hangs more downwards, but is still large even in the fifth.

The umbilical chord at first is short, but large; it sometimes equals the trunk in very small embryos. Afterwards its length increases, but the relative breadth diminishes. Its surface is always unequal and knotted.

Soemmerring has remarked that the sex of the youngest embryos can be distinguished, independently of the genital organs, if they are well proportioned. The most striking difference is found in the structure of the thorax. That of the male is longer, more conical, formed of thicker ribs, and more prominent, with respect to the abdomen and pelvis, than that of the female. In the latter, not only is the whole thorax shorter, but also rather larger above, as far as the fourth rib, and therefore less conical. It is more distant from the pelvis, on account of the greater interval between the last rib and os innominatum, and less prominent, so that where the body is either erect or supine, the symphysis pubis is the most prominent part in the female, and the thorax in the male subject.

The abdomen begins higher in the female, and is large and prominent, expanding towards the genitals: we might say that the female thorax is compressed, and the abdomen tumid.

The distinction is so obvious, in respect to the points now mentioned, that it will not only be readily observed in the well formed embryos carefully compared; but it may even be thought strange that it should have hitherto escaped observation. It will often be noticed, according to Soemmerring, in very small embryos; and if we can ascertain the sex by the organs of generation, we shall readily perceive the distinction in the form of the chest.

## EMBRYO.

The form of the head exhibits another sexual distinction. It is on the whole larger in proportion to the body, but less rounded in the male than in the female: the occiput too is convex, so that the neck is hollowed in appearance, and the vortex is flattened. In the female the form is more globular, the occiput not prominent, and the neck consequently not hollowed, and the vortex spherical.

Some points of distinction may be seen also in the extremities; of which males have the superior rather larger, the scapulae stronger and more prominent, and therefore suitable to the stronger thorax of this sex, the arms rather conical, the fore-arms more muscular, the carpi broader, and the ends of the fingers more obtuse. The lower limbs, adapted to the narrow male pelvis, are contracted above; the thighs are more slender, but the feet very strong, with prominent malleoli and heels. The great toe exceeds the others in size very remarkably. The characters of the female are just the reverse of these. The upper limbs are shorter, with the scapulae more sloping, the arms cylindrical, fore-arms slender, wrists narrow, and ends of the fingers acuminate. The lower limbs, from the superior breadth of the pelvis, are largest above, and diminish conically towards the knees; the heels and ankles are not prominent, and the great toe exceeds the others but slightly.

The spinous processes of the inferior dorsal, and superior lumbar vertebrae form a kind of projecting ridge in the back of the male, where the female presents a depression. The same difference is seen not only in the mature foetus, but also in infants, and in the best proportioned boys and girls.

After describing the progress of the embryo, and the differences of the male and female at this early period, Soemmering alludes to the much disputed question, whether the same powers of body and mind are bestowed on all men, or whether there be not natural diversity in these in different individuals, arising from original differences in the structure of the frame. Attentive examination will shew that the bodies of embryos are marked by native traits of distinction, clearly recognisable at a time, when neither food, education, habits, clothing, nor the operations of disease can have exerted any influence on them. Not to mention that foetuses are born, who, from too delicate an organization of the eyes, shun as the greatest evil, that light, which is our first blessing; that imperfection in the structure of the ears incapacitates some from the ordinary business of life; that others are almost cut off from human society by deficient formation of the organs of voice; that mal-formation of the heart devotes some to an existence of constant suffering, incapable of all exertion of body and mind, while deformity of the limbs circumscribes the powers of others; that many are born without brain, and therefore utterly destitute of all mental faculties; putting all these circumstances out of the question, we notice great differences in the form and proportions of well made embryos. Wide differences exist in the shape, capacity, and firmness of that part of the head which lodges the brain; the countenance varies infinitely in the distance, size, and form of the organs of the external senses; and there are marked diversities in the volume of the chest, and in the strength and form of the limbs.

To our account of the progressive development of the different parts of the body, we shall subjoin a short description of the foetus in its different periods. In the first month it consists of a mere jelly; which is easily destroyed by very little touching, and evaporates almost entirely by heat. Authors have delineated embryos at the end of the first month of the size of a barley corn; or a pea. Soemmering gives a representation of one very elegantly formed, no lar-

ger than a very small pea. At this time the head is fully developed, and much exceeds the rest of the body. The cranium is particularly large. The eyes and mouth are discernible. The figure of the whole is globular, the head and spine being strongly bent towards each other. The position of the bodies of the vertebrae is discernible. The arms are two very small tubercles; the lower extremities are the same; and the coccygeal tubercle is a larger prominence between the right and left of the latter limbs.

In the second months the body becomes more firm and opaque, and its parts are more developed. The mouth and nose are discernible; the eyes distinguished by their blackness; and the ears can hardly be seen without the aid of the microscope. The whole figure is strongly incurvated, so that the coccygeal tubercle, which is larger than the rudiments of the lower limbs, nearly touches the head. At the end of this month the fingers and toes are discernible. Ossification also commences; first in the clavicles, the large cylindrical bones, the lower jaw, frontal and occipital bone; &c. The body may now be half an inch long. The umbilical chord, very short and thick, connects the child closely to the ovum. In the end of the third month the features are well formed. The forehead is very prominent. The general figure still incurvated. The coccygeal tubercle diminishes and disappears. The extremities are fully developed, and the fingers and toes perfectly distinct. The organs of generation are clearly seen; the penis and clitoris being very large, the nymphæ prominent, and the labia thick. The abdomen projects towards the umbilicus. Soemmering has given a most exquisite figure of a male embryo of about 12 weeks. The eye-balls are clearly distinguishable, larger than the opening of the lids. The nose is well formed; and even the philtrum is clearly discerned in the upper lip. There is scarcely a vestige of the coccygeal arch. The size and form of the scapula is evident, and the parts of the extremities in general distinctly seen; even the prominence of several muscles, as the deltoid and biceps, gluteus major, vastus externus, &c.

In the fourth and fifth months the form and proportions approach constantly more nearly to those which the body possesses in future. All the external parts are clearly distinguishable in the 14th and 15th weeks; except the hair and nails. Hitherto the foetus was surrounded on all sides by a large quantity of the water of the amnios; but as it grows now more rapidly than the ovum, it occupies the cavity of that part more completely. The head, in the fourth month, on account of its considerable size when compared to the body, sinks constantly lower in the uterus. The foetus comes completely in contact with its coverings in the fifth and beginning of the sixth months, and consequently the mother usually begins now to feel its motions. On a very rare occasion, Wrisberg saw clearly, for a few minutes, a slight motion of the arms and feet in a foetus of 130 days. He could not discern any beating of the heart or arteries; neither did the muscles of respiration act, when he inflated the lungs. In the sixth month the membrana pupillarum of the eye is very visible. The scrotum is still empty and corrugated. Hair and nails are formed. The integuments still hang rather loosely on the body, so that it has a lean and wrinkled appearance. In a foetus of between 5 and 6 months, the length of the body was 10½ inches; and that of the head, from the vertex to the lower jaw, 3¼ inches.

The length of three foetuses, whose ages were 158, 162, and 170 days, varied from 16 to 19 inches; and their weight from 1lb. 10 oz. to 1lb. 13 oz. All three came into the world alive: the pulsation of the arteries could be clearly felt,

## EMBRYO.

felt, they respired, but cried feebly. They moved their limbs freely, could not suck, but swallowed milk which was poured into their mouths; and they lived several hours.

The size of the fœtus is considerably increased in the last three months. The greater comparative growth of the limbs makes it appear as if the head became smaller; the latter part is about one-third of the body in a newly born child. More fat is accumulated under the skin, so as to make the outline of parts more rounded.

The increase at this time is rather in breadth and thickness than in length. The hair grows longer, and the nails more firm. The *membrana pupillaris* disappears, and the testes descend into the scrotum. A child of seven months can live a few hours only out of the uterus, and those of eight months seldom live a fortnight.

The fœtus is fully developed and mature, so that it can live out of the uterus at the end of the ninth calendar month. Experience has shewn that children may live, when born a fortnight or three weeks before this time, if well taken care of; and it seems probable that a longer interval may elapse before birth: but the necessary uncertainty of the mode of reckoning renders the point dubious. The proportions of parts are very different in the fully grown fœtus from those of the adult. The head is extremely large; and the upper part of the trunk, and upper extremities, are very considerable when compared with the lower parts.

“The size and weight of a child’s body at birth, says Dr. Hunter, are generally over-rated in this country; inasmuch that we are often told, even by those who ought to know, of children weighing from 15 to 20 pounds. So far is this from being true, that I never knew an instance of a child which weighed 12 pounds, and the greatest number a little above half that weight. Dr. Macaulay was at pains, at our hospital, to ascertain the ordinary bulk of newborn children, by first weighing a great number indiscriminately as they were born; and then by giving an order to our matron to weigh occasionally all such as were of a remarkable size in either extreme. Of several thousands born in the British hospital at their full time, while the doctor’s order was attended to, the smallest weighed about four pounds, the largest 11 pounds two ounces, and by far the greater number weighed from five to eight pounds, avoirdupois. In cases of twins, it seldom happens that each attains the weight of a single child. It has been remarked that the first is usually the strongest.”

The measure and weight of the fœtus cannot be much depended on as criteria of its being mature or otherwise: yet if a child is much under between six and five pounds, and shorter than eighteen inches, it may be deemed immature. The following are also characters from which we draw the same conclusion. Thinness of the body, and mobility of the skin; a reddish livid colour of the surface, particularly in the palms and soles, probably from the blood shining through the thin integuments: and a fine woolly covering of the body. Mobility of the parietal bones, and great size of the fontanel. Thinness and shortness of the nails. The eyes being much closed, and the child not looking about at surrounding objects. Coldness of the hands and feet.

The growth of the child, during its residence in the uterus, is very considerable compared to its subsequent increase. According to Haller, (*Element. Physiol. lib. 29. sect. 4. § 17.*) it increases in the first month to a bulk 300,000 times greater than its original size. In the second month its increase is to 48 times the size it possessed at the end of the first. From this time to the full period it will only average an increase of 15 times for each month. At

the end of the three first years, the proportion to the mature fœtus is as 14 to 5: and at the end of the 22 following years, the proportion to an infant of three years, as 8 to 1. The increase in the first month of existence is to that of the last month of growth as 4,885,717 to 1, and the whole increase is from 1 to 108,000,000,000.

The number of twin-cases to single births, according to Süßmilch, is as 1 to 65 or 70: by the same calculator, one instance of three children occurs in 6500 births; but probably it does not happen so often. Four children are extremely rare, and the cases of five are still more extraordinary. Twins live often enough; three children but seldom; and four, perhaps, never.

As a general observation, it may be stated that male children are larger than females. Dr. Clarke of Dublin has given us some interesting facts on this subject from a register of 20,000 births, in a paper contained in the 76th vol. of the *Philosophical Transactions*. The weights of sixty males and sixty females were as follows, leaving out fractions:

		Males.							
lbs.		4.	5.	6.	7.	8.	9.	10.	
Number of children		0.	3.	6.	32.	16.	2.	1.	
		Females.							
lbs.		4.	5.	6.	7.	8.	9.	10.	
Number of children		2.	9.	14.	25.	8.	2.	0.	

He found the dimensions of the head in the male to exceed those of the female: thus, of 120 children, six only measured more than 14½ inches round the head; and all these were males. This greater size of males exposes them to greater difficulty in the birth, and consequently a greater number dies in that process; one half more than of females. The proportion of males born to females was nine to eight: but, in consequence of the greater mortality of the former in parturition, and the first days of existence, the balance in favour of the male sex, out of 20,177 children, was only 483 at the end of a fortnight, although originally 1177. In countries where polygamy is allowed, more females are said to be born than males.

*Position of the Child.*—“The fœtus in utero,” says Dr. Hunter, “is naturally contracted into an oval form, adapted to the figure and circumstances of its habitation. The vertex of the head makes one end of the oval, and the nates the other; one side or edge of the oval is formed by the occiput, the back part of the neck, and the incurved trunk; the other is made by the forehead, and the mass of contracted and conglomerated limbs. The chin is close to the breast, the trunk is bended forwards, the knees are close to the fore parts of the hypochondria, the legs drawn to the back parts of the thighs, the feet or lower parts of the legs decussating each other; and the upper extremities contracted into the vacant space betwixt the forehead and knees. The most common situation of the extremities is not to be determined, as they are found to be a little different in different dissections; and in the living body they vary almost every moment: thence the hands are seen indiscriminately on the head or face, or across one another, or round the knees, or legs; and the legs are sometimes extended, and the feet are placed by the face; or one is in that position, and the other contracted, and the foot downwards.”

“The navel-string, in passing from the child to the placenta, is often variously entangled with the extremities, and frequently winds once or oftener round the neck.”

“When there is a considerable quantity of liquor amnii, the child takes the advantage of room, and the composition of its parts is not so close or globular. In proportion as there

there is less room, its figure is more compacted and moulded to the shape of the cavity of the uterus. In two different cases which I examined, there was so little fluid surrounding the child, though the waters had not been discharged, that the uterus had pressed and moulded all parts of the child into a very ugly form, as if it had been made of dough: and in such cases the hands and more particularly the feet are liable to be compressed and twisted into deformity, on account of their being projecting or pliant parts.

“With regard to the mother, the most common situation of the child, by far is, with its head downwards, and its nates at the upper part of the uterus. Once, perhaps, in twenty or thirty cases, it is the contrary, and presents, as they term it in midwifery, with its posteriors. All the observations that I have been able to make in dissections, and in the practice of midwifery, would persuade me that the child's head is naturally downwards through all the later months of utero-gestation.”

By the position of the fœtus, as we have now described it, rolled up and compacted into an oval figure, it takes up the smallest possible room in proportion to its size. It distends the uterus too equably: and, in order to fulfil this object more completely, the intervals left by the inequalities of the child's body are filled with a fluid (the liquor amnii), and the whole is contained in membranes, so as to form a perfectly oval mass, distending the uterus in all directions. Hence the fluid is more copious in younger embryos, because they cannot be compacted into an oval mass, and are too tender to distend the uterus.

The peculiarities of structure, in various parts of the body, which distinguish the fœtus, will come under consideration, most properly, when we describe the different parts in which they are found. We shall, therefore, merely enumerate them on the present occasion.

The surface of the body is covered every where with a firm sebaceous and white substance, called by some vernix caseosa. This covering, which renders the whole body greasy, cannot be washed off with plain water. It is insoluble in alcohol, oils, or pure water: but some alkalies dissolve part of it, and form a kind of soap. It has often been supposed that this is a sediment from the liquor amnii; but that is very improbable, as the liquor amnii contains nothing unctuous, and there is none of it on the amnios or navel-string. It must, no doubt, be a secretion from the skin.

The cutis, at first thin and gelatinous, is covered by a cuticle in the earliest stages. Proper fat is not formed under the skin before the fourth month; its place is occupied by a kind of jelly-like substance. Afterwards a pretty thick layer of fat is formed over the whole body, next to the skin; but there is very little about the viscera or internal parts: little among the muscles, or in the bony structure. The skin has a very red and vascular appearance; and is said to have this appearance, even in negroes, who are affirmed to change to the black colour a few days after birth. A soft woolly covering, seen particularly about the sides of the face, the back, shoulders and ilia, in young embryos, disappears in the mature fœtus.

The state of the bones in the fœtus has been already alluded to in the article BONES. The jelly, of which the embryo is first composed, becomes more firm and consistent in the fourth and fifth weeks. The materials of the parts which will afterwards be bones, are first changed from the gelatinous consistence, common to all the organs, into cartilage, at first soft and tender, and assuming gradually firmness and elasticity. Its figure represents that of the future bone. It loses its transparency, and white opaque spots

are discerned in it (*puncta ossificationis*) about the seventh or eighth week after conception. These are first observed in the clavicles, ribs, vertebrae, large cylindrical bones, lower jaw and other bones of the face, os frontis, and occipitis. Large vessels are seen ramifying through the cartilage, and distributed on the ossifying points; these secrete the osseous matter, which is there deposited. In simple flat and small bones there is a single point, from which the osseous deposit extends into the rest of the bone. In most others, particularly such as have an irregular figure, there are two, three, or more points, beginning at the same time, and extending in their circumference until they meet. Such bones consist of certain pieces in the fœtus and young child, united by plates of cartilage. In other bones, particularly of the long kind, a principal point is observed at first, forming the body of the bone, or diaphysis. Afterwards, smaller points arise, especially at the ends, which had hitherto remained cartilaginous. These are called epiphyses, and, after their ossification has proceeded considerably, they are still connected to the body of the bone by a plate of cartilage. The ossific points generally commence in the very middle of the cartilage, and extend thence into the circumference. They differ in appearance in the different bones. In the flat ones, particularly of the head, they are thin reticulated scales, perforated with innumerable small holes. The bony fibres, as they are called, extend, in these scales, in a radiated manner, from the centre to their circumference: in the long bones they are short cylinders, with a small depression at each end, and possessing, apparently, parallel fibres: in the round bones they are globular granules; and in those of irregular figure, irregular in their outline, and generally possessing several points.

At the time of birth the ossicula auditus, labyrinth, and tympanum, are completely formed; all the other bones of the body are in a more or less incomplete state.

Physiologists in all ages have attempted to explain how ossification is effected, in what manner the cartilage is removed, and bony substance put in its place: which points we shall probably understand, when the hitherto unveiled mysteries of secretion and nutrition are completely laid open to our inspection. In the mean time, instead of bringing forwards a series of old hypotheses, we shall just quote a passage from Albinus, (Annot. Acad. lib. 7. p. 76). “We may conjecture that there exists, from the first origin of the embryo, rudiments of the cartilages, however small, soft, tender, and approaching to the nature of fluid: or at least that something is generated at that time, which is afterwards cartilage. But of the essential nature of cartilage or bone; of the manner in which cartilage is substituted in the place of bone; how either cartilage or bone is formed from our aliments; and what particular part of the fluids furnishes the materials of this growth; we must confess ourselves ignorant, and shall probably remain so.”

The bones of the fœtus contain much more animal matter, and less earth than those of the adult; they are consequently of a greyish colour, and acquire more of a white or yellow hue, as they advance towards their perfect consistence. The extremities of the long bones, on account of their numerous blood-vessels, are dark coloured. The periosteum is strong and thick, and separates easily. The place of marrow is supplied, in the embryo, by a mere gelatine, which acquires somewhat of a fatty or oily nature towards birth.

The younger the embryo, so much larger is the head in proportion to the trunk and extremities; so much smaller are the bones of the face compared to the cranium; so much larger the organs of hearing; and so much lower and flatter is the lower part of the face. The internal surface of the skull

Skull has no marks arising from the convolution of the brain, nor any grooves for the blood-vessels. The cranium is at first merely membranous; the mode in which it is ossified has been already considered under the article CRANIUM. We may just enumerate here, as peculiarities of the foetal cranium, the want of the frontal, sphenoidal, and maxillary sinuses, of the mastoid processes, and of the meatus auditorii externi, and the imperfect state of the ethmoid sinuses. The condition of the jaws, with their contained teeth, has been considered at large in the article CRANIUM.

The os hyoides has scarcely begun to ossify at the time of birth.

The cavity of the thorax is proportionally larger than in the adult, and more conical. Blumenbach attempts to account for this size by the peculiarities in the circulation, and the consequently greater bulk of the liver. The pelvis is very small, so that there is no room in it for the urinary bladder. The individual bones of the chest and pelvis, as indeed of the rest of the body, will be more particularly described in other articles.

In the upper extremities, the clavicles begin to be formed very early, and attain to a very large size, when the rest of these limbs is extremely small. Thus in the tenth week they are three times the size of the femora. The scapula is also considerable at an early period, and has a piece of ossification double the size of that in the os innominatum. The carpus is completely cartilaginous, as is the tarsus in the lower limbs, excepting the astragalus and os calcis, each of which possesses a small ossific point. The ossification proceeds afterwards more rapidly in the tarsus than in the carpus, probably on account of the erect stature of the human subject, and the share which the tarsus has in supporting the body in that position.

All the bones of the embryo are uniform on their surfaces, where, in the adult, elevations and impressions are found.

The muscles can hardly be distinguished in the three first months, like the rest of the soft parts they seem composed of a mere jelly. The fibrous texture becomes discernible in the following months; when we are able to distinguish tendons also. Such, at least, is the observation of Wrisberg, in an embryo of  $5\frac{1}{2}$  months. The tendons, which are fixed to the bones of the adult, terminate in the periosteum and perichondrium of the foetus, and come away entirely with these membranes.

It is observed, by Soemmerring, that the tendons of the recti abdominis are proportionally broader and stronger than in the adult. The pyramidales are considerably larger. There is a round opening in the linea alba for the passage of the umbilical vessels. The muscles of the internal ear are nearly complete at the time of birth; the intercostals and diaphragm are considerably developed at the same period, and the muscles of the upper more than those of the lower extremities.

The eyes are developed at a very early period, being distinctly visible in the youngest embryos hitherto observed. They appear as black points at the end of the first month. The pigmentum is visible from the first, and is particularly thick and black. It has been correctly observed by Hogarth, that no part of the body grows so quickly, and is so perfect in the foetus, requiring no additional growth after birth, as the iris. The cornea, crystalline lens, and vitreous humor, have a reddish tint. The lens is spherical in its figure. That great peculiarity of the foetal eye, the membrana pupillaris, will be described in the article EYE.

The external ears are developed rather late, as there is

not the slightest trace of them at the end of the first month. The meatus externus is often filled up with the vernix caseosa. The membranous texture of the whole meatus; the covering of the membrana tympani by the membrana mucosa; the attachment of that membrane to the annulus auditorius; the want of mastoid cells are all further explained in the article EAR.

The formation of the nose commences late; and the cavity is small and very incomplete in the foetus, as a necessary consequence of the state of the bones of the head at that time.

The thyroid gland is large and vascular in the foetus.

The thymus, which is of very considerable size before birth, and gradually disappears afterwards, will be considered under that article.

The lungs are small, collapsed, of a red colour, and sink in water.

The mammae are large in proportion to the size of the body. The papilla is small, and not yet surrounded by an areola. The breasts of the male and female foetus do not differ: they contain a whitish fluid, which can be forced out by gentle pressure, and sometimes flows spontaneously in children.

The abdomen is very large in the foetus, and is drawn into a conical form towards the navel in young embryos. The great size of the abdomen may be accounted for by considering, that this cavity holds the bladder, and that the liver and renal capsules are very large. The distance from the end of the sternum to the pelvis, in a newly born child, is one-third of the length of the body; in the adult it is not one-fifth.

In the alimentary canal of the foetus, we observe an almost entire want of valvulae conniventes in the small intestine; and of appendices epiploicae in the large. The appendix vermiformis is a gradual conical contraction of the caecum. The intestines are more or less filled with a soft matter, of a yellowish green colour in the small, and of a dark green, approaching to black, in the large, called meconium. There is very little of this near the stomach; it increases in quantity lower down, and is the most abundant in the large intestines. But in the early months, the latter part of the canal contains no meconium. It is not distinguished by any peculiar taste or smell.

The pancreas is large, and the liver of immense size in the embryo. The kidneys are also considerable, and lobulated on the surface. The renal capsules equal the size of the kidneys. The urinary bladder is very large, equalling the dimensions of the stomach.

The situation of the testis in the abdomen, and its passage from that cavity into the scrotum, will be considered when the testis itself is described.

The heart is proportionally large in the foetus, and occupies a considerable part of the thorax. Hence, on exposing that cavity, this viscus comes immediately into view, and seems in a manner to cover the lungs. The foramen ovale, by which the two auricles communicate; and the equal strength of the two ventricles, will be considered when the heart itself is described. The pulmonary artery of the foetus divides into three branches, of which the middle is the largest. This is termed the *ductus arteriosus*, and it runs directly to join the aorta, immediately below the arch of that vessel. It is often named after Botall, although Galen and others knew it. Its length is about equal to a finger's breadth. It conveys into the aorta a large part of that blood which passed from the right auricle into the right ventricle; more than half of it, according to Haller. This canal is closed very soon after birth, often within a few

days. The umbilical vessels have been already described in a former part of this article. The arteries are found obliterated from the navel to the bladder, very soon after birth, often within a very few days; near the bladder they are very much contracted, but not closed, and give origin to the arteries of the bladder. The umbilical vein, and ductus venosus are closed in the same way. The mode in which the circulation is carried on through the parts now described, is represented in the article CIRCULATION.

The coverings of the brain are at first so thin and transparent, that this organ can be seen through them. It is almost fluid until the 5th or 6th month, and remains very soft even to the time of birth, so that its dissection is difficult. It is always larger in proportion to the body, the younger the fœtus. The nerves are larger in proportion to the body.

*Physiology of fetal existence.*—Some remarks on this subject will be found in the article CIRCULATION. We have only to observe, further, on the subject of the connection between the mother and child, that the mode by which this is effected, notwithstanding it has been a favourite subject of research with the greatest physiologists of all ages, remains still a problem. The account which we have given of the structure of the placenta, shews that the arteries and veins of the uterus have communications with the substance of the former organ; we are, however, entirely unable to state how the blood of the mother, or any nutritive fluid, is admitted into the umbilical vessels; although the obvious impossibility of the fœtus deriving the materials of its growth from any other source, leads us to conclude, without hesitation, that such admission must take place. The reader will probably think that the following quotation, containing Mr. Hunter's opinion, does not tend to elucidate materially this obscure question.

“The blood, detached from the common circulation of the mother, moves through the placenta of the fœtus, and is then returned back into the course of the circulation of the mother, to pass on to the heart.

“This structure of the placenta, and its communication with the uterus, leads us a step further in our knowledge of the connection between the mother and fœtus; the blood of the mother must pass freely into the substance of the placenta, and the placenta most probably will be constantly filled; the turgidity of which will assist to squeeze the blood into the mouths of the veins of the uterus, that it may again pass into the common circulation of the mother; and as the interstices of the placenta are of much greater extent than the arteries, which convey the blood, the motion of the blood in that part must be so much diminished, as almost to approach stagnation.” (Obs. on certain parts of the Animal Economy, p. 135.)

The existence of the fœtus is purely vegetative. Constantly receiving the materials of its nourishment and growth from the juices brought to the placenta by the vessels of the mother, it may be regarded as a new organ produced by conception, participating in the general life, but having its own peculiar life, which is, to a certain degree, independent of that of the mother.

The animal life, or that class of functions by which the animal is connected to the external world, has not yet commenced in the fœtus. Its state therefore cannot, with any justice, be compared to that of a person asleep, in whom these functions are only suspended: but in the fœtus they have not begun.

The fœtus can have no sensations from the surrounding medium: its temperature being invariable, it can have no

object of comparison, which is essential to sensation. The senses cannot act, because none of the causes, which excite them, have hitherto operated. That of touch, being dependent on the others, and serving to rectify the conclusions which they tend to, must of course be inactive. This inaction of the senses supposes a similar state of their nerves, and of the brain. Transmission of impressions is the function of the former; perception of the latter: but neither of those acts can take place when there are no objects to be transmitted or perceived. Memory and imagination flow immediately from perception: judgment arises from one of these three, and gives origin to the will. This connected series of faculties has not begun in the fœtus, because of the want of sensations. The brain is capable of acting, and possesses all the requisites for action; it is not *excitability* but *excitation* that is wanted. The fœtus moves while contained as the uterus; and these motions are considered as symptoms of pregnancy. As all motion arises from some foregoing impression, and as the senses of the fœtus are completely inactive, it is difficult to assign a satisfactory cause for these movements of the child.

The functions of organic life, or those by which the nutrition and growth of the body are effected, must commence almost as soon as the fœtus is conceived. The matter of nutrition arises in its body in an assimilated state, having been prepared by the mother: it enters immediately into the circulating system, without traversing the digestive organs, then nearly inactive. The organs of excretion, which decompose the body, as the lungs, skin and kidneys, are also almost inert. The secretions have hardly commenced.

To the great simplicity of the assimilative process in the fœtus, let us add the remarkable activity of the organs employed in it; an activity which depends on the greater proportion of their vital powers. The whole force of the animal economy seems to be concentrated on the two systems of circulation and nutrition; the processes of digestion, respiration, secretion, and exhalation being exercised, at most, but feebly: the diminished energy of the latter being made up by the increased power of the former. If we consider, moreover, that the organs of the animal life, condemned to a necessary inaction, are gifted with a very small share of vital powers; we shall see that nearly the whole of that living energy, which is destined, in the sequel, to animate all the systems of the body, is, in the fœtal state, concentrated upon those which are concerned in building up the various parts; and consequently that the functions of nutrition and growth possess, at this age, an energy vastly superior to that of any others.

We may refer the reader to a great number of works on the subjects of the preceding article. In the eighth volume of the *Elementa Physiologie*, Haller has displayed his usual erudition and judgment in a complete collection of all the facts ascertained previously to his time. Dr. Hunter's *Anatomia uteri humani gravidi*, folio, and Soemmerring's *Icones embryonum humanorum*, folio, 1799, contain a perfect series of representations of the human ovum; and its contents from the earliest time to its maturity. Dr. Hunter's Anatomical description of the human gravid uterus and its contents, published after his death by Dr. Baillie, 4to. 1794, is a clear and plain description of the subject. We may mention further, Wrisberg *descript. anat. embryonis, observationibus illustr.* 4to. Gött. 1764, or, in the third volume of Sandifort's *Thesaurus*; also, his remarks on the structure of the ovum in the *Göttingen Commentaries for 1773 and 1783*. Roderer *De pondere & longitudine infantum recens natorum in the Göttingen Commentaries for 1753*; and Wrisberg *de vita fœtuum humanorum* *dijudicanda*,

canda, in the same work for 1773. Autenrieth *supplementa ad historiam embryonis humani*, Tubingen, 1797, 4to.

On the comparison of the structure of the fœtus and adult, see C. I. Trew de differentiis hominis nati et non nati, Altdorf, 1736. I. G. Roderer de fœtu perfecto, Strasburg, 1750. Portal in the Mem. de l'Acad. des Sciences de Paris 1770. A. and F. Roefslein de differentiis inter fœtum et adultum, 4to. Strasburg, 1783. On the nutrition of the fœtus; see Lévillé sur la nutrition du fœtus considéré dans les mammifères & les oiseaux. Paris an. 7. & Lobstein dissertation sur la nutrition du fœtus, Strasburg, 4to-1802. The most complete book on the whole of the subject, that is, the structure and development of the ovum, and the anatomical peculiarities of the fœtus, is F. G. Danz Grundriß der Zergliederungskunde des ungeborenen Kindes in den verschiedenen Zeiten der Schwangerschaft. 2 vols. 8vo. 1793, which contains most abundant references to all the sources of information on every part of the subject.

EMBRYO, in *Vegetable Physiology*, εμβρυον, a fœtus, or infant, the CORCULUM of Linnæus, under which term we have already mentioned it, is the most essential part of a perfect seed. When sexual impregnation has not taken place, this organ is defective, however perfect all the other parts of a seed may be, as in the *Cycas revoluta* which bore fruit at the bishop of Winchester's, and is described and figured in the Transactions of the Linnæan Society, v. 6. 312. t. 29, 30. Here every part of the fruit and seed was apparently in the highest perfection, except that a small cavity was only found in the place of the embryo, a defect doubtless to be attributed to the absence of a male plant of the same species. The same has been observed in cucumbers and melons, whose fruits are not the worse in flavour on account of such a deficiency, though dates, when unimpregnated, are known to be much inferior in quality. The embryo or corculum is very conspicuous in the walnut, the garden bean, pea, lupine, &c. In a very poisonous plant, the *Jatropha Curcas*, figured in Gærtner, t. 108. f. 1. this author mentions as a remark of Mr. Boyle, that the nucleus or albuminous part of the seed may be eaten with impunity, if the embryo and cotyledons, or rather perhaps plumula, be taken away. This same circumstance was pointed out by the natives of Sierra Leone to Dr. Afzelius and his companion Borone. The internal structure of the embryo, before it begins to vegetate, is observed by Gærtner to be remarkably simple, consisting of an uniform medullary substance, enclosed in its appropriate bark or skin. When the vital principle is excited to action, vessels are formed, and parts developed, which seemed not previously to exist, as in the egg of a bird. The embryo is generally situated within the substance of the seed, but not always, being entirely external to the body of the seed, though within the skin, in the natural family of grasses or corn. In umbelliferous plants it occupies the very centre of the seed, and in that family its position is reversed; whereas in compound or syngenesious flowers, though equally central, it is erect with regard to the base or insertion of the seed. In the date and some other palms the embryo is lateral and horizontal; while in the cocoa-nut and others it is erect, in the centre of the base of a large albumen. Its direction is either straight, curved, or even spiral. Its form is most simple in plants that have only one cotyledon, or rather no proper cotyledon at all. S.

EMBRYO-WORMS. It is a matter of no small curiosity, to observe the arrangement of the multitudes of the embryo-worms, as they are lodged in the bodies of the viviparous two-winged flies.

An accurate dissection of one these little animals, shews:

very plainly the parts where the embryo-worms are inclosed. This dissection is easily made with a pair of fine pointed scissars, taking off the whole upper shell of the body from the lower; and that part which covers the belly may be turned back upon the corcelet, without disturbing the internal parts by the operation; and the form and arrangement of the parts which contain the embryo-worms in their, will be found very different from that of those which contain the eggs in the common flies. Baker on the Microscope, p. 115. 416. 417. 428. 430.

EMBRYOPTERIS, in *Botany*, from εμβρυον, an embryo, and πτερον, a wing, as appears from an examination of Gærtner's figure; though, from the construction of the word, it seems to be derived from πτερον, a fern, or brake. Hence this name, as it at present stands, is liable to a double objection, as being compounded of one previously established, *Pteris*, and still more as conveying a false idea of its own application. *Embryopterum* would have been correct and unexceptionable, and we should without scruple have adopted such an alteration; but the name is altogether superfluous, the plant in question being a *Diospyros*, under which head its generic character may be seen. We have, therefore, here only to add to that list of species the following.

*Diospyros glutinifera*, Roxb. MSS. (*Embryopteris peregrina*; Gærtner v. 1. 145. t. 29. f. 2. E. glutinifera; Roxb. Coromand. v. 1. 50. t. 70.) Stamens numerous. Leaves oblong, palish beneath. Seeds eight or ten. This is a middle-sized evergreen tree, growing in the moist cool valleys among the mountains of the northern Circars, flowering in March and April. The natives call it Tumika, and eat the fruit, which Dr. Roxburgh describes as strongly astringent, and not palatable. The Malays name it Mangostan-utan, and the Dutch Lym-appel. The wood is of an indifferent quality, and not much used. The branches are smooth. Leaves alternate, stalked, oblong, sometimes inclining to elliptic, and occasionally a little heart-shaped at the base; entire, smooth, palish beneath. Flowers white; the males in small axillary clusters; females on a separate tree, solitary and larger. Berry globular, about two inches in diameter, of a rusty yellow, and covered with a rusty farina when ripe. Gærtner mistook the top of the fruit for the base, and hence erroneously describes the calyx as superior. He also mistook the radicle of the embryo for a simple cotyledon, but his profound knowledge led him to suspect that a cavity in the other extremity might be the real seat of the embryo, and that the circumambient substance was consequently a vitellus. We presume this cavity to have arisen in the plumula, from a shrinking of the parts, after the vital principle was extinct, his specimen being an old one, and therefore his suspicion was, so far, well founded. He describes the albumen as gelatinous in its centre, and dissolving in water, to which Dr. Roxburgh's specific name, and the Dutch appellation, both seem to allude. S.

EMBRYOTHLASTES, Εμβρυοθλαστες, in *Surgery*, an instrument wherewith to crush the bones of an embryo, or dead child; so as to make it easier of extraction, and prepare it for the embryuleus, to draw it out of the womb.

EMBRYOTO'MIA, from εμβρυον, a fœtus, and τεμνω, to cut, the operation of cutting into the womb, in order to extract the fœtus. See CÆSARIAN Section.

EMBRYULCUS, from εμβρυον, and ελχω, to draw, an instrument used in extracting dead children. See CROTCHET.

EMBS, or EMS, in *Geography*, a small town of Germany, which, till the peace of Lüneville, belonged in part to the landgrave of Hesse Darmstadt, and in part to the

prince of Nassau Dietz, to whom it has been ceded; is chiefly remarkable for five sulphureous baths in its neighbourhood.

EMBS, or *Hohenembs*, a small district of Germany, in the circle of Swabia, south of the county of Bregentz and the lake of Constance, about 10 miles long and 5 broad, erected into a county by Charles V.

EMDEN, or EMBDEN, a town of the kingdom of Holland, capital of the department or province of East Friesland, which, till the year 1807, belonged to Prussia, to the sovereign of which it had been sold by the United Provinces of the Netherlands, in 1744. It is situated on the Ems, not far from the sea, and near the lake Dollart; 30 miles N.E. of Groningen. N. lat.  $53^{\circ} 20'$ . The harbour is commodious; it holds 400 vessels.

Emden had gained considerable commercial importance, from having been declared a free-port by the king of Prussia, in 1751. Its situation was extremely convenient for the Dutch, to carry on their commerce with the greatest security in time of war; particularly during the late wars between England and France, when the Texel was blockaded by the English. Goods used to be forwarded, on the river Ems, to within a short distance of Munster in Westphalia; from which city they were conveyed by land-carriage to the interior of the continent, to Switzerland, and Italy. In the year 1781, the number of ships cleared outwards was 1025, inwards 1004; but in 1799, there entered at Emden inwards 3402 vessels, and 2151 failed outwards. In 1784, Emden had 273 vessels of the tonnage of 38,578 tons, besides 43 vessels for the herring fishery; in 1804, the number of ships employed in the carrying trade only, belonging to Emden, exceeded 500.

The population of Emden, in the year 1785, amounted to 7968 individuals, without the garrison: in 1802, Emden counted 10,400 inhabitants. The herring fishery produced annually near 1000 tons of herrings. It employed 60 boats, and a great many hands among the lower orders of the people.

EMEGIAGEN, a town and fortress of Africa, in the empire of Morocco.

EMENDALS, an old term still used in the accounts of the Inner Temple; where, so much in emendals at the foot of an account, on its balance, signifies so much in the bank, or stock of the house, for reparation of losses, and other occasions.

EMENDATIO *Panis & Cerevisia*, the assize of bread and beer; or the power of supervising and correcting the weights and measures belonging to them. See ASSIZE.

EMERALD. Of this mineral there are two distinct varieties: the true emerald, and the beryl or aquamarine, both of which we shall proceed to describe.

*True Emerald.*—Emeraude Verte, *Fr.* Schmaragd, *Germ.*

The colour of emerald is pure prismatic green, of various degrees of intensity; but the deep-coloured varieties pass occasionally into grass and verdegris-green, and the lighter ones into greenish-white. The only natural state in which it has been hitherto met with is crystallized. Its primitive form is a regular hexahedral prism; sometimes the lateral edges are replaced by secondary planes, forming a dodecahedral prism; or, the solid angles are replaced by small triangular facets; or, the terminal edges are bevelled, sometimes very slightly, and sometimes so deeply as to present the appearance of terminal truncated pyramids. The length of the prisms seldom greatly exceeds their diameter. The crystals are middle-sized and small, rarely large: they are generally implanted, and sometimes imbedded, and al-

ways occur in clusters. The internal lustre is vitreous and shining; the fracture is small and imperfectly conchoidal, passing into obscurely foliated. It is transparent or translucent, and exhibits a double refraction. Its hardness is somewhat superior to that of quartz. Sp. gr. 2.72 to 2.77.

It is fusible *per se* before the blow-pipe, but with difficulty, into a semi-opaque whitish glass. With borax it melts easily, and without effervescence. Its constituent parts, according to Vauquelin and Klaproth, are as follows:

	Vauq.	Klapr.
Silex	64.50	69.11
Alumine	16.	15.
Glucine	13.	12.5
Lime	1.6	0.25
Oxyd of chrome	3.25	0.25
Oxyd of iron	0.	1.
Water	2.	0.
	100.35	98.

It is at present found only in Peru, in the valley of Tunia or Tomana, between the mountains of New Granada and Popayan; and near Puerto Viejo, in the district of Manta, in the same province. It is said to occur in veins, passing through argillaceous schistus, and other primitive rocks, and is accompanied by quartz, feldspar, black schorl, mica, calcareous spar, and iron pyrites.

Emerald is reckoned among the gems, and when of a fine colour, and without flaws, is highly esteemed. The most magnificent specimen known of this mineral was presented to the church of Loretto, by one of the Spanish kings: it consisted of a mass of white quartz, thickly implanted with emeralds, more than an inch in diameter.

The emerald is supposed by Dutens and others to have been unknown to the ancients; and it is certain, that several of their descriptions of the smaragdus are not at all correspondent, except in colour, to the modern emerald. But among the twelve kinds of smaragdus, or rather pseudo-smaragdus, enumerated by Pliny, one of them, and that the most valued, appears to be the real emerald. With regard to its colour, this naturalist says, "Nihil omnino viridius comparatum illis viret." He ranks it, in estimation, immediately after the diamond and pearl; and adds, that so pleasing was its tone of colour, that by common consent the engraver was ordered to spare it: "Quapropter decreto hominum iis parcitur, scalpi vetitis." The emeralds of the ancients were procured from Ethiopia; but these mines have now been for many ages forgotten and neglected; nor is it certain that any except the Peruvian emeralds are now extant. The only one that may with any probability be referred to an African origin, is that with which pope Julius II. adorned the papal tiara: for as this sovereign died in 1513, and the enterprize of Pizarro against Peru did not take place till 1545, it is not unreasonable to conclude that the emerald in question is not an American one. There are two specimens, which formerly obtained great estimation as invaluable Ethiopian emeralds, which the superior accuracy of modern knowledge has stripped of their value, both in the eyes of the naturalist and of the jeweller. The one is a tabular mass, of the weight of 28 lbs. now in the abbey of Reichenau, and which formerly belonged to Charlemagne; this Mr. Coxe has ascertained to be green fluor. The other is the "Sacro cattino de Smeraldo orientale," which was deposited in the treasury of Genoa, and was not allowed to be seen except in consequence of an order from the senate: in this the acute eye of M. Condamine

mine detected some air-bubbles, which induced him to consider it as only green glass; and subsequent examination has fully confirmed his suspicion.

*Beryl, or Aquamarine*—Emeraude verte bleuatre, Hauy. Eder beril, Wern. Its colour is mountain-green, passing into whitish-green, yellowish-green, wine-yellow, and honey-yellow, or blueish-green, passing into small and sky-blue. Its colours are almost always pale; and when two exist in the same crystal, they are generally arranged in alternate layers. The primitive form and varieties of crystallization are the same as those belonging to the true emerald; but the actual and proportional length of the prisms is much greater. The lateral planes of the crystal are striated longitudinally, so as sometimes to give the prism a cylindrical appearance. The joints perpendicular to the axis are generally very distinct, and most commonly are plane surfaces; but sometimes, like those of articulated basalt, they are formed by a convex protuberance let into a cup-shaped concavity. Another singular accident to which this mineral is subject is, that a prism, which at its lower end is solid, terminates occasionally in a brush-like extremity, composed of numerous small prisms. Sometimes a joint is so disposed, that it is no longer perpendicular to the axis of the prism; in consequence of which, an elbow is produced, as if the prism had been broken across, and the pieces ill cemented together again. Sometimes, again, the axis of the prism is perforated. The size of the crystals varies from capillary to 18 inches long by 2 or 3 in diameter. Its external lustre is shining and glistening; internally, it is brilliant and vitreous. The cross fracture is small, and imperfectly conchoidal; the longitudinal fracture is foliated. It is commonly transparent, passing into translucent; its hardness is nearly the same as that of the emerald. It is electric by friction, and often phosphorescent. Sp. gr. 2.68 to 2.72.

According to the analyses of Vauquelin and Rose, it is composed of,

	Vauq.	Rose.
Silex	68.	69.
Alumine	15.	14.
Glycine	14.	14.
Lime	2.	0.
Oxyd of iron	1.	1.
	100.	98.

Beryl occurs imbedded in primitive rocks, also in veins accompanied by quartz, felspar, fluor spar, garnet, mica, and topaz. It is found in Brazil, in Saxony, in the south of France, near the village of Barat, whence very large but ill-coloured crystals have been procured, and occasionally in the highest mountains of Aberdeenshire. But the finest specimens of all come from Siberia, and are found chiefly in three places of this vast country.

First, in the Uralian mountains, about 25 leagues to the north of Ekaterinbourg. The specimens that come from this mine are of a small size, but a very good colour.

Secondly, in the Altaic mountains, between the Ob and the Irtysh. The crystals from this mine are large, and of a greenish-blue colour, but coarse, and mixed with quartz.

Thirdly, in the granitic mountain of Odon Tchelon, in Daouria. This is by far the most interesting and the richest mine. There are in fact three different mines at different heights on this mountain, from which beryls are procured: that situated the lowest is in a mass of semi-decomposed granite, mixed with ferruginous clay and nodules of Wolf-ram; in this there are irregularly disseminated minute

prisms of beryl, rarely exceeding an inch in length, and of a greenish-yellow colour. About 800 yards above this mine is an irregular vein of micaceous clay, from which are procured the most valuable crystals; their colour is a pure pale green, and their dimensions not very unfrequently amount to seven or eight inches in length by two in diameter. At the very summit of the mountain is situated the third mine, in a vein of white indurated clay, mixed with arsenical pyrites: the beryls that it yields are generally of a greenish-blue colour, but sometimes of a pure but pale sky-blue, and very transparent.

Beryl is ranked by courtesy among the gems, but its value is greatly inferior to that of the emerald.

EMERALD, *Oriental*, is a greenish variety of sapphire.

EMERALD, *Counterfeit*. The manner of making counterfeit emeralds in paste is this: take crystal prepared, two ounces; common-minium, or red lead, four ounces; mix these well together, then add of good verdegris two penny-weights, and crocus martis made with vinegar, eight grams. Mix all these well together, and set the whole in the hottest part of a potter's furnace, as long as the fire lasts. It must be put in a strong crucible, and covered with a lute. When it is cold take off the lute, and, if it is baked enough, it will be clear to the bottom; otherwise relute the pot, and put it into the furnace again. Twenty-four hours commonly are sufficient for making this; sometimes it requires a little more. The paste, thus made, is harder than ordinary, and is of a fine colour, and capable of a good polish. Neri's Art of Glass, p. 128.

If the paste be desired of a very deep emerald colour, take prepared crystal one ounce; red-lead, six ounces and a half; of verdegris, three penny-weights and thirteen grains; and of crocus martis, made with vinegar, ten grains. This requires a longer baking than the other, and is less hard, though of a deeper colour.

The proportions of these ingredients may be varied at pleasure, and the colour be made of all degrees of deepness; but the more lead is added, the more baking is required, and, after all, the paste will be so much the softer.

EMERALD *Colour, in the Glass Trade*. The way of giving this beautiful dye to glass is this: in the pots of melted metal, made of pulverine, and without manganese, when the matter is well purified, put a little crocus martis calcined with vinegar. About three ounces of this crocus is enough for a hundred weight of glass; let it stand till thoroughly mixed, then put into every hundred weight of metal two pounds of calcined brass; this must be added at six different times, letting the metal stand two hours every time. When this is all in, make a proof of the metal; and if it has any blueishness, add more crocus martis, a small quantity at a time. When the whole is of a fine leek-green, let it stand twenty-four hours to mix thoroughly, and then work it. Neri's Art of Glass, p. 51.

EMERALD, or *Emerald*, in *Heraldry*, is used in lieu of vert, or green, in blazoning the arms of dukes, earls, &c.

EMERGENI YEAR, in *Chronology*, is the epocha, or date, whence we begin to account our time.

Our emergent year is sometimes the year of the creation; the Jews use that of the deluge, or the Exodus, &c. The emergent year of the Greeks was the establishment, or at least restoration, of the Olympic games by Iphitus. The Romans accounted their years from the building of the city, *AB U. C.* that is, *AB URBE CONDITA*. See *EPOCHA*.

EMERITA AUGUSTA, in *Ancient Geography*. See *AUGUSTA* and *MERIDA*.

EMERSA, *FOLIA*, in *Botany*, applies to such leaves of aquatic plants as are raised above the surface of the water, and

and which are usually of a different figure from those that are *immersa*, or sunk under water. See **LEAF**.

**EMERSION**, in *Physics*, the rising of any solid above the surface of a fluid specifically heavier than itself, into which it had been violently immersed, or thrust.

It is one of the known laws of hydrostatics, that a lighter solid, being forced down into a heavier fluid, immediately endeavours to emerge; and that with a force, or moment, equal to the excess of a weight of a quantity of the fluid above that of an equal bulk of the solid.

Thus, if a solid be immersed in a fluid of double its specific gravity, it will emerge again, till half its bulk, or body, be above the surface of the fluid.

**EMERSION**, in *Astronomy*, is when the sun, moon, or other planet, begins to re-appear, after its having been eclipsed, or hid by the interposition of the moon, earth, or other body.

The difference of longitude is sometimes found by observing the immersions and emersions of the first of Jupiter's satellites.

The immersions are observed from the time of Jupiter's being in conjunction with the sun, to his opposition; and the emersions, from the opposition to the conjunction; which two intervals are usually six months a-piece, and divide the year between them.

But when Jupiter is in conjunction with the sun, and fifteen days before and afterwards, there is nothing to be observed; the planet, with his satellites, being then lost in the light of the sun.

**EMERSION** is also used when a star, before hid by the sun, as being too near him, begins to re-appear, and to get out of his rays.

**EMERSION**, *Scruples*, or *Minutes of*, an arch of the moon's orbit, which the moon's centre passes over, from the time she begins to emerge out of the shadow of the earth to the end of the eclipse. See **ECLIPSE**.

**EMERSON**, **WILLIAM**, in *Biography*, an eminent English mathematician, was born in 1701, at Hurworth, a village near Darlington, in the county of Durham. His father kept a school, and was a good mathematical scholar: to him, and to a young clergyman, the subject of this article was chiefly indebted for his early instruction in the different branches of the mathematics. He attempted to keep a school himself, but soon found his temper unfitted for the task; and, on the death of his parents, having come into the possession of a moderate competence, he devoted himself to a life of studious retirement, where he composed a great number of treatises, by which his name has been long known to all lovers of science; and from the profits of which he redeemed his little patrimony from some incumbrances which he found on it. He enjoyed a good state of health till nearly the close of his life, when he had frequent and very severe attacks of the stone; a disease to which, in the year 1782, he fell a victim, when he had attained to the 81st year of his age. Mr. Emerson was singular in his behaviour, dress, and conversation. His manners were rough, coarse, and often very disagreeable. In conversation, he was positive, dogmatical, and impatient of contradiction. His relaxation from study was sometimes working in the fields, and sometimes the amusement of fishing, to which he was much attached. When he had any treatise for publication, he always went to London, to attend to the printing himself. He was an able mathematician; but his style as a writer is not adapted to smooth the path of science for beginners. His works, which are very numerous, are now chiefly superseded by other and more popular writers, who

have had the better art of facilitating the studies of young persons, by a more agreeable style, and an easier method of demonstration. His "Treatise of Mechanics" is that which is now best known, and to which reference is more frequently made than to any of his other works.

**EMERSTORFF**, in *Geography*, a town of Germany, in the archduchy of Austria, seated on the Danube; 6 miles above Crems.

**EMERUS**, in *Botany*. See **CORONILLA**, species 1.

**EMERY**, *Schmiengel*; Wern. in *Mineralogy*. Its colour is greyish-black or blueish-grey. It occurs massive and disseminated: when in mass, it is generally encrusted with magnetic iron ore, pyrites, and mica; the latter substance frequently penetrates the whole mass, giving it, when broken, a silvery appearance. It possesses a glistening or glimmering lustre. Its fracture is fine-grained uneven, passing into splintery. Its hardness is about equal to Adamantine spar, cutting flint and rock-crystal with great ease. It is heavy, and not very easily frangible. When most free from iron, it consists, according to Tennant, of

Silex	314
Alumine	92.
Iron	4.6
	100.

When highly impregnated with iron, this ingredient amounts to about 36 per cent.

Emery is procured from the islands of the Archipelago, especially from Naxos; also from the neighbourhood of Alocer, in Extremadura, in Spain. Much of the emery used in France is imported from the islands of Guernsey and Jersey, in the British channel. It is also found at Ochsenkopf, in Saxony, in beds of talc and steatite.

This mineral is largely used for cutting and polishing, by lapidaries and workers in glass and metal. The mode of its preparation is very simple. Being pulverized in an iron mortar, it is carefully washed over, and thus separated into five or six different degrees of fineness, according to the work in which it is to be employed.

**EMER-YAPAR**, in *Geography*, a town of Asia, in Tibet; 17 miles from Che-tcheou.

**EMESA**, **EMISA**, *Emissa*, or *Emesus*, in *Ancient Geography*, an ancient city of Syria, situated on the eastern bank of the Orontes, between Apamea and Laodicea Cabiosa. During the troubles which agitated Syria, this city was seized by an Arabian, named Sampsiceramus, who, assuming the title of king, held Emesa and its small territory, undisturbed by the Seleucidæ, engaged in more important concerns. He left two sons, Jamblichus and Alexander; the former of whom succeeded his father, and was much attached to the Romans. In the civil wars of Rome, he took part first with Cæsar against Pompey; and afterwards with Antony against Octavianus. After the victory gained by the latter at Actium, Antony, dreading his concurrence with other princes in favour of the conqueror, and upon this suspicion, having got him into his power, caused him to be put to a most cruel death. Upon his death, Antony bestowed the kingdom on his brother Alexander, who, continuing faithful to his benefactor in his greatest distress, was taken prisoner by Octavianus, and not only deprived of his kingdom, but carried in triumph to Rome; and afterwards put to death. His son, Jamblichus II., was favoured by Octavianus, and restored by him to his father's kingdom, after he had remained for some time in a state of exile. He had some successors, who supported the dignity of this small kingdom; but the last of its kings, whose name is recorded

corded in history, was Azizus, who, falling in love with Drusilla, the sister of Agrippa Minor, embraced the Jewish religion, in order to marry that princess. This small kingdom was afterwards, as we may presume, seized by the Arabians; for we find that, some years after, it was possessed by the Iturzans. Emesa was the birth-place of the emperor Heliogabalus; and it was one of the cities in which the Romans planted colonies. It is now called *Homs*; and though formerly a strong and populous city, it is at present only a large ruinous town in the pachalic of Damascus, containing not more than 2000 inhabitants, partly Greeks and partly Mahometans. An aga resides here, who holds, as a sub-renter of the pacha of Damascus, the whole country as far as Palmyra. The pacha himself holds this farm, as an appanage deriving immediately from the sultan. Hama and Marra are held in the same manner; and these three farms pay 400 purses, or 500,000 livres (about 20,000*l.*), but they produce nearly four times that sum. Volney's *Travels in Egypt and Syria*, vol. ii.

EMETICS, in *Medicine*, from ἐμέω, *I vomit*; those substances which excite vomiting, or cause the stomach to reject its contents upwards.

Medicines of this class have been employed, for the purpose of clearing the stomach, from the earliest ages to which any authentic records of practice extend. In the time of Hippocrates, indeed, the use of emetics seems to have been very general, not only as a remedy in diseases of some severity; but as a popular expedient for relieving slight indisposition, especially the occasional derangements of the organs of digestion, brought on by indulgence in eating and drinking. Hippocrates even recommends them to the healthy as a preservative; and he has stated many precepts with respect to the proper times for administering them, in conjunction or alternation with fasting, bathing, exercise, &c. under various circumstances of health and disease. See his treatise on Diet, book iii. and elsewhere. Yet it must be remarked, that the catalogue of emetic substances in the possession of the ancients was very imperfect, in comparison with our own; and consisted either of uncertain and almost inert articles, on the one hand, or of severe and rather unmanageable substances on the other. Hippocrates prescribed powdered hyssop in about a gallon of water, as a vomit for corpulent men, with the addition of a little vinegar and salt; it was to be drunk at first gradually, and afterwards more quickly.

Celsus has likewise detailed a set of rules, relative to the use of emetics, among the means of reducing the habit, if too plethoric. He says, "emetics are more useful in the winter than in the summer, because in that season there is more phlegm, and a greater heaviness in the head. They are of no advantage to those who are slender, or who have a weak stomach; but are useful to plethoric, and bilious people, whether they have suffered from repletion, or have their digestion impaired. For if they have taken more than the digestive power is able to concoct, they ought not to risk the danger of its corrupting; and if it is already corrupted, it is proper to expel it in the most expeditious way possible. Hence, when any person is attacked with bitter eructations, together with pain and weight in the region of the stomach, let him immediately resort to a vomit. It is also proper for those, who have a sense of heat in the breast, a frequent spitting or nausea, or a noise in the ears, or humour in the eyes, or a bitterness in the mouth," &c. "I grant," he observes farther, "that emetics should not be taken for the sake of indulging a luxurious appetite; but that they are advantageous in some forms of disease, I know from experience: I admonish those, however, who wish to enjoy good health and attain old age, not to make a daily

use of them. If any one wishes to vomit after taking food, he should first drink warm water only, if he vomits easily; if with some difficulty, he should add a little salt or honey to the water: but he that intends to vomit in the morning, should drink *mulze* (a mixture of wine and honey,) or eat hyssop, or radish, and then drink warm water, as has been already directed. All the other substances, which the ancient physicians prescribed, are injurious to the stomach. If that organ is weak after the vomit, a little food should be taken, of a proper kind; and if the fauces have been much irritated, three cups of cold water may be drunk. He who has used a vomit, if it were in the morning, ought to take a walk, then anoint, and afterwards sup; but if after supper, he should bathe on the following day, and sweat in the bagnio: he will do well to make the next meal slight, and that of roasted meat, with austere and unmixed wine, stale bread, and food of the driest kind." He concludes with this observation: "he that chuses to vomit twice in the month, will find it more advantageous to do it for two days successively, than if he were to repeat it on the fifteenth day; unless this intermission should occasion a weight at his breast." *De Medicinâ*, lib. i. cap. 3.

These statements shew, that the use of emetics constituted a part of that regimen, among the ancients, in which more of their time was occupied, and more attention bestowed, than the moderns in this country are accustomed to give to the subject. They also resorted to vomiting, as a remedy in fevers, and other diseases. See Celsus, lib. iii. cap. 7. And emetics, as well as purgatives, were employed after the termination of fevers, upon theoretical principles, to evacuate the remainder of the morbid matter, after its virulence was supposed to be subdued by concoction. In the use of purgatives, we find some remains of this theory among the people, as well as among the ignorant part of the profession, even at the present day. Hippocrates seems to have believed, that this remnant of the morbid matter, like a piece of leaven, if retained after the crisis, was the occasion of the return of the disease. "Quæ per morbos post judicationem intus relinquuntur, morborum reversiones faciunt." Aphor. 12. sect. ii.

The direct effect of an emetic is the evacuation of the contents of the stomach. Hence the principal purpose, for which it may be used, would seem to be the removal of morbid or noxious matters from that organ; whether consisting of its own secreted juices, in a diseased condition of indigestible food, either from quantity or quality, of poisons, or of other noxious substances, which may have been swallowed. Hence the vulgar resort to emetics on every occasion of what is popularly called a "foul stomach," or of "bile on the stomach." These conditions are presumed to exist, when such symptoms as the following are present: when there is a want of the usual appetite, or, in addition to that, a loathing of food; or, when, after food, or during the time of its digestion, an uneasy sensation of fullness, weight, and distension is felt in the stomach, especially if accompanied with heartburn, flatulency, and acid or bitter eructations; and to these may be added frequent head-achs, particularly in the morning.

Now, although it cannot be questioned, that the removal of the present contents of the stomach, in such cases, generally affords more or less relief; it is not the less certain, that this relief is seldom very durable; for the noxious matters are more frequently to be considered as the effects, than as the causes of the morbid condition of the stomach: they depend most commonly on the weakness and loss of tone in the muscular fibres of the stomach, and the imperfect secretion of the gastric juice; and these, it is obvious, are not to be cured

by vomiting, though their consequences may be relieved by this for a longer or shorter time. On the contrary, there can be no doubt, that frequent vomiting renders the stomach less able to retain, what is thrown into it, and to weaken its powers of digestion. "They are unhappy," says Dr. Cullen, "who trust to this mode of relief, and have therefore frequent recourse to it; for I am certain, from much experience, that frequent vomiting hurts the tone of the stomach, and often makes the symptoms of indigestion recur more frequently and sooner than they otherwise would have done." *Treatise on the Materia Medica*, vol. ii. p. 465.

The same author remarks, that the effects of vomiting, and the degree of disease that required it, are commonly judged of by the vulgar, and often by physicians, though not always fairly, by the appearance of the matter thrown up. For example, there is commonly thrown up a considerable quantity of viscid mucus; and to this the symptoms of the disease are frequently imputed. "It is, indeed, possible," he adds, "that an unusual accumulation of mucus in the stomach may be the cause of want of appetite, and other symptoms of indigestion, but not always so justly as might be imagined. The mucous follicles of the stomach constantly pour out a considerable quantity of this matter; a considerable quantity is to be found in the stomachs of the most healthy persons: and the experiments of M. Senac shew, that there is always a considerable quantity of it in the mucous follicles, which may very readily be squeezed out very copiously in vomiting. It is not, therefore, to be judged that the quantity, and even a large quantity, thrown up by vomiting, had either previously existed in the cavity of the stomach, or that such a mucus had been the cause of the morbid symptoms, indicating therefore the repetition of vomiting. It has been upon occasions of this practice, that I have known repeated vomiting, not only to give no durable relief, but rather to increase the supposed cause."

The evacuation, however, occasioned by an emetic, is not confined exclusively to the stomach; the upper part of the intestines, namely, the *duodenum*, and even part of the *ilium*, is commonly evacuated at the same time. The peristaltic motion of the alimentary canal may proceed either downwards or upwards; and when the action of any part of it is directed in one way, the next adjoining portion follows in some degree the same direction. Whence, in vomiting, as the peristaltic motion of the stomach is directed upwards, so the motion of the duodenum, is directed in the same way, and it pours its contents into the stomach; from which it will appear that a considerable portion of the upper part of the intestines may be evacuated. The most clear proof of this inverted motion of the duodenum, in vomiting, is, that, especially after repeated vomiting, a quantity of bile is poured into the stomach, and is in consequence thrown out by the mouth. This frequent appearance may depend entirely upon the quantity of bile for the time present in the duodenum; but it probably extends farther. In the action of vomiting, as the contraction of the diaphragm and of the abdominal muscles concurs at the same time, the whole viscera of the abdomen are strongly pressed: this pressure must affect the gall-bladder and the biliary ducts, and occasion them to pour out their contents very largely, which, being thrown into the stomach from the *duodenum*, may be ejected by vomiting. It is commonly supposed, indeed, by the vulgar, that the bile thus thrown up existed previously in the stomach, and in some instances it may have been so: but it is more probable that it had been brought from the *duodenum*, and even from the gall-bladder and biliary ducts in the way just explained. For had the bile been previously lodged in the stomach itself, it

might have appeared in the first vomitings, as well as in the last; but it happens, in almost all instances, that the bile is thrown out by the mouth only after repeated vomitings, and often after repeated straining in the organs employed in that act.

Dr. Cullen attributes some good effect to the pressure on the liver and abdominal viscera, just alluded to, in obviating the stagnations which are liable to occur in the system of the *vena portarum*, and which lay the foundation of obstinate diseases. He affirms, that he knows no means of expediting the circulation in the liver so powerful as that of vomiting. Other writers have expressed an opinion of the advantages derived from this mechanical pressure and conqassation of the viscera of the abdomen, in exciting the mesenteric circulation, as well as that of all the glands, and consequently in favouring and aiding all their secretions. (See Dr. Fothergill, *De emeticorum usu*, &c. Cullen, loc. cit. p. 468.) Dr. Cullen, however, considers the effects of this mechanical compression and motion as most evident in the viscera of the thorax, especially in promoting expectoration: hence the utility of vomiting in catarrhal affections, more particularly the chronic catarrh of old people. He also allows that it may be useful in many cases of pulmonary consumption; but justly adds, that we cannot, either from theory or experience, find any reason to believe that frequent vomiting is adequate to cure that disease.

There is also another indirect action of vomiting, which is beneficial to the system, arising from the sympathy between the stomach and the skin. This sympathetic consent between the vessels of the skin and of the stomach is very great, inasmuch that the several states of each may be communicated to those of the other. Thus, wetting the skin relieves thirst, as was proved by Capt. Bligh and his party; and in the same way the action of an emetic excites particularly the action of the vessels on the surface of the body; and this action is excited by doses of these medicines, which are not sufficient to excite vomiting. Hence most of the substances employed as emetics are capable of exciting perspiration. We are disposed to believe that a similar sympathy, between the stomach and the vessels in the cells of the lungs, is the cause of the utility of vomiting in producing expectoration, rather than the mere mechanical pressure of the lungs.

The action of vomiting, when excited rather briskly, by the general shock or conqassation of the whole frame, affects the nervous system at large as a stimulant. In this way the utility of an emetic, in the commencement of a continued fever, is partly to be accounted for. Dr. Cullen, indeed, attributes the advantages of vomiting in that case to the relaxation of the spasm of the extreme vessels in the skin, according to his theory of fever; and partly, perhaps, the operation may be accounted for in this way: but it is to be remarked, that other expedients, which have nothing in common but the general shock which they occasion to the nervous system, also contribute to cut short or to alleviate fever, under the same circumstances; a brisk purgative, for example, cold affusion, or the shower-bath, &c.

It is also observed by Dr. Fothergill, who ascribes considerable effects to the *stimulant* operation of emetics, that, in spasmodic disorders, and several others of the nervous kind, which seem to arise principally from the torpor and languor of the digestive organs, emetics are often of essential benefit. He mentions CHOREA, or St. Vitus's Dance, certainly not the least obstinate of nervous complaints, as often relieved by emetics.

The same celebrated physician cautions us particularly respecting the administration of emetics to those who are of

## EMETICS.

plethoric habit, or who labour under diseases, in which general or local plethora is present. If the symptoms, in such cases, indicate the propriety of employing emetics, blood-letting ought, in his opinion, to precede their use; for there is danger, left in the temporary convulsion of straining to vomit, the distended vessels should be ruptured, or the blood be carried with too great force, or in too great quantity, to parts where the resistance of the vessels is too weak to withstand it. Thus, if the vessels of the head should give way, a sudden and fatal apoplexy may be brought on; if those of the lungs should be ruptured, a spitting of blood, followed by a slow, but not less fatal consumption, may be induced, or similar mischief may be occasioned in other viscera. (Loc. citat.) In cases, however, in which these plethoric diseases are to be suspected, the prudent practitioner will, even after blood letting, consider emetics as inadmissible, unless the necessity of immediately emptying the stomach of its contents be great and pressing.

The occasion, on which such a necessity is the most obviously paramount to all other considerations, is when poison has been recently swallowed. In this case, the greatest risk is from the operation of this substance on the stomach, and therefore the most expeditious means of inducing vomiting are to be adopted. If the poison be of the vegetable narcotic species, such as opium, it often so completely paralyzes the muscular fibres of the stomach, as that ordinary emetics have no power to excite its action. The white vitriol, or sulphate of zinc, operates in general almost instantaneously, especially if swallowed with a large quantity of water. When this has failed, we have known a few grains of the blue vitriol, or sulphat of copper, dissolved in warm water, given with success, where opium had been swallowed. A strong infusion of ipecacuanha, drank copiously, has sometimes effectually emptied the stomach under similar circumstances.

In a fit of inebriety, when vinous or fermented liquors have been drunk to the extent of inducing a state approximating to apoplexy, the safest, perhaps, and best mode of emptying the poison from the stomach, consists in pouring in warm water as copiously as it can be swallowed; since it at once dilutes the inebriating liquor in the stomach, and therefore diminishes its effects, and urges the stomach to expel it. See DRUNKENNESS.

Although emetics have been found to be beneficial in the early stages of all fevers, as already mentioned, yet we must not here omit to notice their peculiar good effects in the scarlet fever, as observed by Dr. Withering. (See his Treatise on the Scarlet Fever.) This fact, indeed, had been pointed out by Tournefort (in his voyage to the Levant, tom. i.), and other writers; but Dr. Withering recommends vomiting, repeated according to circumstances, as the most essential remedy for this disease. "In the very first attack," he says, "a vomit seldom fails to remove the disease at once. If the poison has begun to exert its effects upon the nervous system, emetics stop its further progress, and the patients quickly recover. If it has proceeded still further, and occasioned that amazing action in the capillaries, which exalts when the scarlet colour of the skin takes place, vomiting never fails to procure a respite to the anxiety, the faintness, and delirium." Dr. Willan also speaks highly of the utility of emetics in scarlet fever, with sore throat, but has not found it necessary to repeat them so often as Dr. Withering advised. Treatise on Cutaneous Diseases, ord. 3.

Emetics are sometimes useful in asthma, and in hooping-cough, probably upon the same principle as in chronic catarrh, before noticed. They have been said also to assist in

forwarding a gall-stone through the ducts into the intestines as well as an urinary calculus from the kidney to the bladder, through the ureter, by the mechanical agitation of the body, which they occasion. But their operation in this way must be very feeble and uncertain, and may do injury, when the calculi are large or angular. Sydenham employed strong emetics as remedies for dropsy; but they generally purged also, to which operation their good effects, when they did prove beneficial, must be the rather attributed.

The catalogue of medicines possessing an emetic power, which were in use among the ancients, although sufficiently ample, contained, as we have already said, substances either of feeble and uncertain action, or of acrid and violent qualities. The hellebore was sometimes fatal. Even Sydenham complained in his time, that an emetic substance, which was "safe, and at the same time effectual," was a desideratum in the *Materia Medica*. His active emetic consisted of the *crocus metallorum*, as it was then termed, or *crocus antimonii*, (a preparation made by deslagrating the sulphurated antimony with an equal weight of nitre,) which being soluble in any acid, was most uncertain in its operation, as it depended upon the quantity of acid with which it met in the stomach. The ipecacuanha root appears to afford that substance to us, which was a desideratum in the time of Sydenham.

We may, with Dr. Fothergill, consider emetics under three heads, the very mild, the moderate, and the strong or drastic; not to mention the irritation of the throat with a feather; the exercise of swinging, sailing, or whirling round certain objects of sight, &c. which are not resorted to as remedies. Among the mildest means of exciting vomiting, is filling the stomach suddenly with a large quantity of liquid; simple warm water is generally sufficient for the purpose; but its operation is aided, when other substances of little power are combined with it: thus, infusions of green tea, of chamomile flowers, the *carduus benedictus*, broths, &c. may be employed for this purpose. Again, when it might not be proper to give an emetic substance, in such a dose as might of itself excite vomiting, by the assistance of copious draughts of warm water, small doses may serve the purpose of evacuating the stomach, and even of obtaining the other effects to be derived from vomiting.

The moderately active emetic substances are those which are at present in general use; namely, the ipecacuanha, and the tartar emetic, or tartrate of antimony, in small doses; and also some other substances, when much diluted with warm water, which might be of too inflammatory a nature if given alone, in such quantity as to produce vomiting; such are, an infusion of the root of horse-radish, or a tea-spoonful of mustard as prepared for the table, some preparations of the squill, the asarum, &c. The ipecacuanha was first introduced as a remedy for dysentery; but it is now ascertained that its utility in that disease depends upon its purgative quality.

The metallic salts formed with sulphuric acid are active emetics, and may be arranged in the strongest or drastic class. The least violent of these is the white vitriol, or sulphate of zinc, which has been chiefly employed on account of the suddenness of its operation, when poisonous matters have been taken into the stomach: but, in order to render its effects certain, the dose must generally be large, and if it is not thrown out again immediately, it is apt to continue a disagreeable nausea, or even a vomiting, longer than is necessary. Dr. Cullen says, "I find that the purpose of this medicine (that is, a sudden vomiting,) may commonly be obtained by employing a large dose of ipecacuanha, either in powder or in the wine; and by following this soon after with a large

draught of warm water impregnated with chamomile, or rather with what is more at hand, a tea-spoonful of table-mustard; the business may be commonly very effectually executed."

The preparations of mercury are seldom employed as emetics. The sulphat, or turpeth mineral, has been chiefly used, but its operation is violent.

Dr. Darwin observes, that "the quantity of the dose of an emetic is not of so great consequence as of other medicines, as the greatest part of it is rejected with the first effort. All emetics are said to act with greater certainty when given in a morning, if an opiate had been given the night before. For the sensorial power of irritation of the stomach had thus been in some measure previously exhausted by the stimulus of the opium, which thus facilitates the action of the emetic; and which, when the dose of opium has been large, is frequently followed on the next day by spontaneous sickness and vomitings, as after violent intoxication." *Zoonomia*, part 3. art. v. 2. I.

**EMETIC POWDER**, called also *powder of Algaroth*, from the name of its author, is a precipitate of antimony; or butter of antimony sweetened and softened by repeated lotions. See **ANTIMONY**.

**EMETIC TARTAR**, is now called *Antimonium Tartarifatum*. See **ANTIMONY**.

**EMETIC WINE**, *vinum antimonii*, is only white wine, wherein is infused some glass of antimony. See **ANTIMONY**.

Small doses of emetic wine have been recommended as deobstruent and sudorific in slow fevers, in many chronic diseases, and especially in an obstinate rheumatism. See *Medic. Ess. Edinb. abr. vol. i. p. 170.* and *Huxham, Obs. de Aere & Morb. epidem.*

**EMETZ**, in *Geography*, a town of Russian Siberia, in the government of Tobolsk; 28 miles W. of Ilichim.

**EMEU**, in *Ornithology*, the common name of the Cassowary, a large bird of the ostrich kind.

**EMILE**, in *Geography*, a small town of France, in the department of the Seine and Oise, chief place of a canton in the district of Pontoise, with a population of 1800 individuals. The canton contains 20 communes and 13,843 inhabitants, on a territorial extent of 127½ kilometres.

**EMILI, PAUL**, in *Biography*, a modern historian, was born at Verona. In Italy he obtained a great character, and was brought into France by the cardinal de Bourbon, in 1487, who patronized him till his death. After this he was obliged to teach the languages for a subsistence. He undertook to write the history of France, for which he was rewarded with a canonry in the cathedral of Notre Dame. This history he brought down, in ten books, from Pharamond to the 5th year of Charles VIII.; it was published at different times; and likewise altogether at Paris in the year 1539, and has been several times re-printed and translated into foreign languages. His style is pure, but sometimes too concise, and even bordering on the obscure; he is nevertheless to be regarded as the first writer who gave to French history a just form and method. He died at Paris in the year 1529, leaving behind him a very excellent character: his morals were as pure, as the language adopted in his works was chaste and elegant. Bayle.

**EMILION, SAINT**, in *Geography*, a small town of France, in the department of the Gironde, near the river Dordogne; six miles E. of Libourne, remarkable for the excellent wine which grows in its neighbourhood.

**EMILIUS, ANTHONY**, in *Biography*, professor of history in the university of Utrecht; was born Dec. 20th, 1589, at Aix la Chapelle, where his father had retired for the sake of

his religion. He received the early parts of his education in his native country, and finished his classical studies at Dort, under the famous Gerard John Vossius: he then went to Leyden and other universities, and spent some years in foreign travel. On his return to his native country he succeeded Vossius as rector of the college of Dort, and some time after he went to Utrecht to exercise the same office, where he was afterwards elected to the professorship of history, an office in which he continued till his death, November 10th, 1660. His lectures, for more than twenty-six years, were taken from the annals of Tacitus. He published, about the year 1651, a collection of Latin speeches and poems. Bayle.

**EMILLAGUE**, in *Geography*, one of the Pelew islands.

**EMINENCE**, a little hillock, or ascent, above the level of the adjoining champain.

**EMINENCE** is also a title of honour given to cardinals.

The decree of the pope, whereby it is appointed, that the cardinals should be addressed under the quality of eminence, bears date the 10th of January, 1630. They then laid aside the titles of *illustrissimi*, and *reverendissimi*, which they had before.

The grand master of Malta is likewise addressed under the quality of eminence.

The popes John VIII. and Gregory VII. gave the same title to the kings of France. The emperors have likewise borne it.

*Eminentissimus*, the superlative of eminent, hath of late been attributed to the cardinals.

**EMINENTIAL EQUATION** is used by some algebraists in the investigation of the areas of curvilinear figures; for a sort of artificial equation, containing another equation eminently. *Hayes Flux. p. 97.*

**EMINENTLY, EMINENTER**, in the *Schools*, is used in contradistinction to *formally*, and in the same sense with *virtually, viz.* to denote that a thing possesses, or contains, any other in a more perfect or higher manner than is required to a formal possession thereof.

Thus an angel is said to have prudence eminently; as he has it in a higher and more perfect degree than it is in man, in whom it is formally.

For one thing to contain another eminently, there are usually required two conditions. 1. That the containing be of a more excellent nature than the contained. 2. That the less excellent be some way contained in the more excellent; *viz.* either as in its productive cause, or by some similitude, or as to the manner and order of acting, &c.

**EMIR**, a title of dignity, or quality, among the Turks, and Saracens, attributed to such as are relations or descendants of their great prophet Mahomet.

The word is Arabic, and literally signifies *prince*. It is formed of the verb **אמר**, *amar*, which is originally Hebrew; and in both these languages signifies *to say*, and *to command*. This is a title given to all the nobility of the first rank in the empire of the Mogul and in Tartary. The plural of this term is "Omra."

The emirs are held in high veneration, and have alone the privilege of wearing a green turban. On the borders of the Holy Land there are several emirs sovereign princes; as the emir of Gaza, and the emir of Terabea, over whom the grand signior has but little authority. The title emir, at first, was only given to the caliphs: in Persia they were also called *emir zadeb, q. d. prince's son*; whence by abbreviation of emir, they formed *mir*; and of *emir zadeb, mirza*. In after times, when the caliphs had assumed the title of sultans, that of emir remained to their children, as that of Cæsar did among the Romans.

At length, the same title of emir came to be attributed

to all who were judged to descend from Mahomet by his daughter Fatimah, and who wear the green turban.

EMIR is also a title, which being joined to some other word, frequently denotes an office or employ; as the *emir al omera*, commander of commanders, who, in the time of the caliphs, was chief of the councils and armies.

The appellation emir is also applied by the Turks to all viziers and bashaws, or governors of provinces. (See BASHAW, &c.) Add, that *emir akhor*, vulgarly *imrahor*, is master of the horse to the grand seignior.

*Emir alem*, vulgarly *miralem*, standard-bearer and director of all the standards of the empire.

*Emir bazar*, the provost, or superintendant of the markets, who regulates the prices of provisions.

The *emir bagge*, or *badj*, denoting pilgrimage, or prince conductor of the pilgrims of Egypt to Mecca, is bashaw, or pacha of Damascus. See CARAVAN and DAMASCUS.

*Emir al moslein*, or *emir al moumenin*, i. e. commander of the faithful, or the believers, was a title assumed by the Almoravides and Almohades, who reigned in Africa and Spain.

EMIR-BACHA, in *Geography*, a town of Asiatic Turkey, in the province of Natolia; 80 miles W. of Tocat.

EMISSARIA, in *Anatomy*, are the veins which pass into the skull from the external parts of the head, and terminate in the sinuses of the dura mater. These openings are described in the article CRANIUM. The veins are sometimes called after Santorini, an Italian anatomist. See VEINS.

EMISSARIUM, in *Antiquity*, a sluice, or drain, to draw off the water used in watering gardens, fields, &c.

EMISSARY, formed of *e* and *mitto*, *q. d.* I send out, a trusty, dextrous, able person, sent secretly, to sound the sentiments and views of another, to make him some proposal or overture; or to spread reports, watch the actions, motions, and countenance of a contrary party or person, in order to make advantage of them all. See SPY.

The leaders of parties have abundance of emissaries employed in their service, who inform them of what passes every where, that they may take their measures accordingly.

EMISSION, the act of throwing, or driving a thing, particularly a fluid, from within, outwards. The ancients took vision to be performed by the emission of visual rays from the eye.

But the term emission is chiefly applied among us to the expulsion or ejaculation of the seed.

EMISSION of Heat.—All the heat we experience in the world is derived from three sources; viz. from the sun; from compression, which comprehends collision and friction; and lastly, from the decomposition and composition of bodies.

It is hardly to be doubted, that the emanation of heat from the sun, like the emanation of light from the same source, is not constantly the same; and it is recorded in history, that at certain times the light of the sun has been observed to be pale, or less bright than usual; and had the thermometer been in use amongst the ancients, it would probably have been observed that the dimness of light was accompanied with a proportionate diminution of the usual heat; for these alterations, as far as we can conjecture, seem to depend upon the size of the spots which cover the surface of the sun at different and uncertain times.

The direct rays of the sun on the same part of the surface of the earth, are more or less hot according to the time of the year, the clearness of the atmosphere, the state of the wind, and the colour or other quality of the spot upon which they fall. On this island, in the summer season, the direct rays of the sun seldom raise the thermometer to 110°. But in other climates, especially within the tropics, they

raise it much higher; sometimes as high as 150°. We must not, however, believe the strange accounts of their melting lead or firing gun-powder; for those rays cannot produce any such effect, provided they are not concentrated, or assisted, by artificial means.

It is not on account of the sun's being nearer or farther from us, that we receive much more heat at one time of the year than at another; for the difference of its distance is too small to produce any sensible effect; nor is it owing to the sun's emitting more caloric rays at one time of the year than at another. But we receive more heat in summer than in winter, 1st, because the sun being nearer to our vertex, or to the zenith, in the former, than in the latter season, its rays have a shorter way to pass through the atmosphere, and are of course less obstructed by it. And the same cause renders the sun's rays hotter about the middle, than at the commencement or the close of the same day: 2dly, we receive more heat when the sun is higher, because in that case a greater quantity of its rays fall upon any given portion of the surface of the earth; than when it is lower, and its rays come in a direction more oblique; and, 3dly, because in the summer season the sun remains longer above the horizon than in winter.

With respect to the cause of the emission of heat from the body of the sun, we cannot pretend to have the least knowledge. It is generally supposed that the sun is a body of fire; but it is impossible to say, whether it is an aggregate of caloric, independent of other matter, or a compound body undergoing a gradual decomposition. It was, some time ago, also supposed, that the sun emitted only rays of light, and that the action of those rays upon terrestrial bodies, extricated the heat from the latter. But the recent discovery (made by Dr. Herschell,) of the caloric rays of the sun suffering a different refraction from that of its luminous rays, besides other considerations, renders this supposition vain. Excepting from the sun, no sensible degree of heat is derived from the moon or from any other celestial object.

The immediate production of heat by the other means that have been mentioned above, viz. by compression, collision, friction, composition and decomposition of bodies, arises either from the caloric being squeezed out of a body, like water out of a sponge; or from an alteration of the capacities of bodies for containing heat. We shall endeavour to illustrate these processes.

I. Experiments shew, that when a certain substance is compressed into a narrower space, a quantity of heat comes out of it, and is communicated to the surrounding bodies. On the contrary, when a certain substance is expanded into a larger space, it absorbs a quantity of heat from the surrounding bodies; for these bodies are cooled in consequence of it. Thus, if you wet your hand, and then expose it to the ambient air, the water, in the act of expanding itself into the form of vapour, absorbs a quantity of heat from the hand, which is thereby sensibly cooled. If, by means of a condensing engine, air is compressed in a proper vessel, heat is extricated from it; and if the operation be performed quickly, a quantity of heat will be emitted, which is sufficient to set fire to tinder, and other light combustible bodies. When the steam of water is condensed, heat is deposited by it upon those bodies which are in contact with it.

Wood rubbed against wood, or against any hard body; metal rubbed against metal, or against any other hard body; in short, solid bodies rubbed or knocked against each other, are thereby heated, often so far as to become red-hot.

By this means, heat may be produced where there is no oxygen, so that in those cases it cannot be derived from the

## EMISSION.

decomposition of that air. This has made some persons suspect that heat is not the effect of a peculiar substance called *caloric*; but that it is only a peculiar movement of the particles of bodies. The most striking experiments relative to this subject were made by count Rumford (Phil. Trans. for 1798. p. 1.) He took a cannon, not yet bored, having a projection of two feet beyond its muzzle, a part which is usually cast with the piece, in order to insure the solidity of the metal throughout, by the pressure which its weight occasions. This piece was reduced to the form of a cylinder, joined to the cannon by a smaller neck, and a large hole was bored in it; the whole cannon was then made to revolve on its axis by means of the force of horses, while a blunt steel borer was pressed against the bottom of the hollow cylinder, by a force equal to about 10,000lb. avoirdupois; the surface of contact of the borer with the bottom of the cylinder being about two square inches. This apparatus was wrapped up in flannel, when its temperature was about 65°. In half an hour, when the cylinder had made 960 turns, the horses being stopped, a mercurial thermometer was introduced into a perforation in the bottom of the cylinder, extending from the side to the axis, and it stood at 130°, which count Rumford considers as expressing very nearly the mean temperature of the cylinder. The dust or scales, abraded by the borer, weighed only 837 grains, or about  $\frac{1}{650}$ th of the whole weight of the cylinder. In another experiment, the cylinder was surrounded by a tight deal box, fitted with collars of leather, so as to allow it to revolve freely, and the interval between the cylinder and the box was filled with 19 pounds of cold water, which was excluded from the bore of the cylinder, by oiled leathers fixed on the borer; and after two hours and a half the water was made to boil. Hence count Rumford calculates that the heat produced in this manner, by the operation of friction, was equal to that of nine wax candles, each three quarters of an inch in diameter, continuing to burn for the same time.

Reasoning upon these results, count Rumford thinks, that the heat, thus produced, cannot be extricated from the bodies concerned; and he is led to ask "What is heat?—Is there any such thing as an *igneous fluid*?—Is there any thing that can with propriety be called *caloric*?"

He then says, "We must not forget to consider that most remarkable circumstance, that the source of the heat generated by friction, in these experiments, appeared evidently to be *inexhaustible*."

"It is hardly necessary to add, that any thing which any *insulated* body, or system of bodies, can continue to furnish *without limitation*, cannot possibly be a *material substance*: and it appears to me to be extremely difficult, if not quite impossible, to form any distinct idea of any thing, capable of being excited, and communicated in these experiments, except it be *motion*."

"I am very far from pretending to know how, or by what means, or mechanical contrivance, that particular kind of motion in bodies, which has been supposed to constitute heat, is excited, continued, and propagated, and I shall not presume to trouble the Royal Society with mere conjectures."

It must, however, be considered, that there is no friction which does not produce compression; *viz.* a contraction of the bulk of the bodies concerned, at least for a time; and therefore that the *caloric* is forced out of the bodies themselves; and, being communicated to the surrounding bodies, produces the usual signs of heat. It is a strong corroboration of this assertion, that substances, which are not compressible, are not heated by mechanical force; thus, a flint

will only be broken, but a piece of soft metal will be heated, by the strokes of a hammer. Thus, also, you may place any weight upon a quantity of water, without altering its temperature, because the compressibility of water is next to nothing; but if you place an additional weight upon a quantity of air; the bulk of the air will be contracted, and its temperature will be raised.

By about 15 or 20 smart and quick strokes of a hammer on the end of a soft iron rod of about a quarter of an inch in diameter, placed upon an anvil, an expert blacksmith will render that end of the rod visibly red-hot; and the softer the iron is, the quicker the effect will take place. But the production of vivid red sparks from a piece of steel, when struck against the edge of a flint, is a phenomenon not less curious. These particles are scraped off by the flint, and are of course compressed so as to become red-hot.

"One of the most remarkable circumstances, attending the production of heat by friction," says Dr. Young, "is the discovery of professor Piéctet, that it is often much more powerfully excited by soft substances than by harder ones. In making some experiments in a vacuum, in order to examine how far the presence of air might be concerned in the effects of friction, he accidentally interposed some cotton between the bulb of his thermometer and the cup, which was subjected to the friction of various substances as it revolved; and he found that the soft filaments of the cotton excited much more heat, than any other of the substances employed."

II. When a body heated above the actual temperature of the atmosphere, is placed amongst other bodies, the superfluous heat of the former is communicated to the latter; for there is no known body that can effectually intercept the transition of heat from one substance to another. But there is a remarkable phenomenon attending the communication of heat, which is neither very obvious, nor easily observed. This is, that in the distribution of heat amongst a variety of substances, some bodies absorb more of it than others, though they be all placed exactly in the same situation; hence different bodies are said to have different *capacities* for absorbing heat. (See HEAT, SPECIFIC HEAT, or SPECIFIC CALORIC.) So that if a certain quantity of heat is communicated to a mixture of equal weights of water and of mercury; the water will imbibe a much greater share of that heat than the mercury, and yet both will appear of the same temperature.

Now it has been found that by mixing certain bodies together, their capacities for absorbing heat is diminished; therefore they part with a portion of their heat, which is of course communicated to the surrounding bodies. Thus, when a pint of spirit of wine is mixed with a pint of water, the mixture grows sensibly hot, because their capacities for containing heat are diminished in consequence of their action upon each other. And it is to be remarked that whenever heat is emitted in the act of mixing fluids, as in the above-mentioned example of water and spirit, or of water and sulphuric acid, &c. a concentration of bulk takes place; thus the above mixture of a pint of water with a pint of spirit will be found to measure less than two pints.

In combustions, the heat which is first communicated by the contact of an ignited body, or otherwise, decomposes part of the combustible body, and of the surrounding oxygen air, which produces more heat, and this decomposes more of those bodies, and so the combustion proceeds and continues as long as there are combustibles and oxygen air ready for the process. See EXCITATION of heat.

EMISSION of Light. The perception of objects, which we receive through our sight, is obtained by the intermediation of

## EMISSION.

of something; which we call *light*. Hence the blind must judge of the presence of particular objects, by means of the sound, or the smell, or the touch, &c. but not by the means of light. In short, light does not sensibly affect any other part of our bodies, besides the eyes. It follows then, that something must pass between any object we see and our eyes, but concerning this something we have no certain knowledge. A variety of conjectures and hypotheses have been offered; but of these hypotheses two only may deserve our attention. Descartes, Huyghens, and others, thought that a subtle fluid was dispersed throughout the universe; that the luminous bodies, such as the sun, the stars, a lighted candle, &c. put that fluid, not in a progressive, but in a certain vibratory motion; (somewhat like the motion which is communicated to the air by sonorous bodies;) and that this motion, being communicated to the nerves of our eyes, rendered the luminous objects perceptible to us. Newton and his followers suppose that light is a real emanation from luminous objects; *viz.* that a subtle fluid, consisting of certain peculiar particles of matter, proceeds from the luminous bodies; and by entering our eyes, excites in us the sensation of light, or the perception of luminous objects. A variety of facts and considerations seems to render this Newtonian hypothesis of light by far the most probable of the two. See the article **LIGHT**.

Admitting then Newton's hypothesis, several consequences, which naturally depend upon it, demand a particular illustration; *viz.* this emission of light must consist of particles; those particles must have a very minute, but determinate, size;—they must be at certain distances from each other; must move with a certain velocity, and must have a certain momentum. Several remarkable discoveries that have been made in astronomy, and in other branches of natural philosophy, enable us to determine the above-mentioned particulars, not with absolute precision, but within certain limits of probability. The facts upon which this probability rests, are as follows.

If a small hole be made in a screen, and the screen be placed before our eyes, as about the distance of five or six feet; and if a luminous body, as a red-hot coal, be repeatedly passed before that hole, on the other side of the screen, we must naturally perceive the hole luminous at intervals of time. But if the interval of time, during which the coal is not before the hole, be less than the tenth part of a second, then the hole will appear constantly luminous, exactly as if the red-hot coal were held steadily before it. This shews that the impression of light upon our eyes continues a certain time after the removal of the luminous objects. This is also the reason why, when a stick with a lighted extremity is quickly turned round in a circle before our eyes, we perceive an uninterrupted luminous circle.

The duration of the impression of light upon our eyes is longer or shorter, according as the object is more or less luminous; so that the impression is proportionally strong. See the article **VISION**.

Astronomers have observed, that the eclipses of the satellites of Jupiter appear to take place sooner than the time which is determined by the tables of their motions, when the planet is nearer to us; and later when that planet is farther from us. Hence it is naturally conjectured, that light moves progressively, and equally; *viz.* that it employs a certain time in going through a certain space; and this conjecture is corroborated by other astronomical observations. The calculations, which have been made upon these appearances, shew that light moves at the astonishing rate of, at least, 170,000 miles per second; so that in its motion from the sun to us, light employs about  $9\frac{1}{2}$  minutes.

If a small hole be made in a screen, and several persons are situated on one side of the screen; every one of them looking through that hole at a different object placed on the other side of the screen; it is evident that the various streams of light from those objects to the eyes of the observers, must pass through the same small hole in different directions, and without disturbing each other, at least in an observable degree. This shews, that the particles of light must be so very small, and so distant from each other, as not sensibly to obstruct each other's passage through a very narrow aperture.

In some experiments (rather imperfect) which were made by throwing the focus of a concave mirror upon the extremity of a very delicate beam, which was nicely suspended, a slight motion was thereby communicated to the beam; whence it was deduced, that the light thus collected had a sensible momentum. From the weight of the beam, and from the motion which it had received from the impulse of the light (upon the supposition that its motion was occasioned by it); also from the above-mentioned velocity of light; it was calculated, that the quantity of matter, which was contained in the light which was thrown upon the end of that beam, during one second of time, and which was collected from a reflecting surface of about four square feet; amounted to no more than one twelve hundred millionth part of a grain. (Priestley's *Hist. of Light, Vision, &c.* per. vi. sect. i. chap. 3.) These facts, joined to our daily experience, seem to authorize the following conclusions.

1. Since every physical point of a luminous object may be seen from every point of an immense spherical space which surrounds it, when no opaque body is interposed, it follows, that the streams of light, which proceed from all the points of visible objects, and move in all manner of directions, are past all conception. If this be alleged as an objection to Newton's theory, the least reflection will shew, that it offers an objection equally great, if not greater, to the other hypothesis that has been mentioned above; but the following reasoning will, in great measure, clear the difficulty with respect to Newton's hypothesis.

2. It has been mentioned above, that the impression of light remains a certain time upon our eyes, and (in the experiment with the red-hot charcoal) it has been shewn to remain about one-tenth part of a second; but suppose it to remain only during the 100th part of a second. Then it is evident, that if 150 particles of light be emitted in a second from a single point of a luminous object, as from a point on the surface of the sun; these particles will be more than sufficient to give our eyes an uninterrupted vision of that point; yet still these particles, on account of their immense velocity, may be more than 1000 miles distant from one another, and, of course, may leave room enough for millions of other particles to pass in all directions. Canton's *Calcul. Ph. Tr.* vol. 58.

3. The waste of the substance of a luminous body, arising from the emission of light, considering the minute nature of its particles, is very trifling, even with respect to the sun, which has been the great fountain of light during so many centuries. Dr. Priestley, alluding to the above-mentioned experiment, where an impulse was communicated to a beam by concentrated light, says, "Now the light in that experiment was collected from a surface of about four square feet, which reflecting only about half what falls upon it, the quantity of matter contained in the rays of the sun, incident upon a square foot and half of surface, in one second of time, ought to be no more than the twelve hundred millionth part of a grain. But the density of light at the surface

surface of the sun is greater than at the earth in the proportion of 45,000 to 1; there ought, therefore, to issue from one square foot of the sun's surface in one second of time, in order to supply the waste by light, one-forty thousandth part of a grain of matter; that is, a little more than two grains in a day, or about 4,752,000 grains, which is about 670 pounds avoirdupois, in 6000 years." *Hist. of Light, &c.* p. 390.

4. In consequence of the motion of light, it is evident, that if a luminous body were suddenly placed in the heavens, at the same distance that the sun is from us, we could not possibly see it before the lapse of  $8\frac{1}{2}$  minutes. Also, when we behold a celestial object, we do not see it exactly in the place where it actually stands; but we see it in the place where it stood some time before.

5. Light moves in straight lines, as long as it goes through the same uniform medium, or through a vacuum.

6. When we direct our eyes towards certain polished surfaces, we frequently see in them the appearances of objects, which are situated in places quite different from those in which we see them. In this case the rays of light coming from those objects fall upon the polished surfaces, and from them they are *reflected* (that is, *sent back*) to our eyes. Those objects then are said to be seen by reflected light, and the surfaces in which their appearances are seen are called the *reflecting surfaces*. Indeed, every body which does not itself emit any light, (as is the case with all those which cannot be discerned in a dark room,) are seen by reflected light; for the light which is emitted from the sun, from a candle, from a fire, &c. falls upon those bodies, and is from them reflected to our eyes; but that light is reflected irregularly on account of the inequalities on the surfaces of most bodies; so that though all bodies which do not shine of themselves, are seen by reflected light; yet they are called reflectors, or are said to have reflecting surfaces, only when those surfaces are smooth and polished, in which case they reflect the light regularly, so as to represent the images of other objects, that are placed before them. See REFLECTION OF LIGHT.

7. In its passage from one body into another, or from a vacuum into any substance, and *vice versa*, light is often bent in its direction; and that bending is called the *refraction of light*. See REFRACTION OF LIGHT.

8. Light is likewise bent in its direction, when it passes close by the surfaces of bodies; and this bending is called the *inflection of light*, which see.

The sources of light are various, but they may be comprised under the following enumeration.

1. The celestial bodies, which shine either by their own light, as the sun and the stars; or by reflected light, like the moon and the satellites.

2. The *aurora borealis*, and other meteors, whose nature is not as yet distinctly known.

3. Bodies that are in a state of *combustion*, and emit heat as well as light.

4. The *electrical light*; and,

5. The *phosphorescent bodies*, of which there are several species, *viz.* 1. The *phosphorus* properly so called, which is considered as an elementary substance. 2. The living animals which have the property of shining in the dark, such as glow-worms, lantern-flies, &c. 3. Those bodies which absorb light when exposed to it, and then emit it in the dark; such are several precious stones, calcareous bodies, Canton's phosphorus, the Bolonian stone after due preparation, &c. 4. The bodies which emit light when they are heated to a certain degree; fluoric stones, several marbles, calcareous earth, &c. have this property. 5. The

substances which emit a light either quite white, or tinged with different shades of red or blue, by attrition; *viz.* by being rubbed or struck against each other. Most stones of the silicious kind possess this property. 6. And lastly; those bodies which emit light without any sensible heat, whilst they actually are under a state of decomposition; and of this sort are most animal matters, and some vegetable substances, especially rotten wood.

The doubtful nature of the *ignis fatuus*, or *jack-a-lantern*, may perhaps also be reckoned amongst the phosphori. See AURORA BOREALIS, ELECTRIC LIGHT, METEORS, PHOSPHORUS, PHOSPHORESCENT BODIES, and IGNIS FATUUS.

EMITES, in *Natural History*, a name used by some authors for the chermites, a beautiful species of white marble, of which the tomb of Darius, and many other of the great works of antiquity, were made. It was valued for its fine polish.

EMLY, in *Geography*, a village of the county of Tipperary, province of Munster, Ireland, the see of a bishop; which was united to Cashel in 1568. It is 15 miles W. from Cashel.

EMLYN, THOMAS, in *Biography*, an eminent nonconformist divine, was born at Stamford, in the county of Lincoln, in the year 1663. His parents, though accustomed to attend the religious service of the established church, thought so favourably of the principles of the Protestant dissenters, that they determined to educate their son for the ministry among persons of this description. Accordingly, he was placed for academical instruction in the year 1678, under the care of Mr. Shuttleworth, who resided at Sulby, near Welford, in Northamptonshire. In the following year he was admitted at Emanuel college, in the university of Cambridge; but afterwards returned to Mr. Shuttleworth, under whose tuition he remained for four years. With a view to the enjoyment of superior advantages, he removed, in 1682, to the academy of Mr. Doolittle in the vicinity of London, and in this situation he diligently availed himself of the collateral means and opportunities of improvement, afforded him by an access to books, and intercourse with literary persons; and made such improvement in the knowledge, connected with his profession, that he was encouraged to commence the exercise of his profession in December, 1682. His mind, at this early period, disdained the shackles of established systems of theology; and he determined to inquire freely, and to exercise, independently of the controul of authority, the right of private judgment. It was favourable to his future improvement, that he was not under a necessity of immediately connecting himself with a congregation, and of devoting his whole time to necessary preparation for the public services of his profession. In the year 1683, he became chaplain to the countess of Donegal, and accompanied her to Belfast in Ireland, where he had a liberal appointment, and was treated with respect and kindness. The countess married sir William Franklin, a gentleman of considerable property in the west of England, who offered our young divine a valuable living in that country; but not approving the terms of ministerial conformity, he declined the acceptance of it. His sentiments, however, were so liberal, that he regularly attended the public services of the established church, and was himself attended in the evening, when he officiated in the countess's hall, by the minister of the parish, with whom he cultivated an intimate acquaintance. He likewise occasionally officiated in the parish church, having obtained, without subscription, a licence to preach from the bishop of the diocese. At this time he visited Dublin, and

and his services were so acceptable to the congregation, of which Mr. Daniel Williams and Mr. Joseph Boyce were pastors, that he was afterwards induced to settle among them. In the mean while a variety of circumstances occurred in the agitated state of the north of Ireland, and the domestic disunion of the family of his patroness, which rendered it expedient for Mr. Emlyn to remove to England. Accordingly in the year 1688, he came to London, where he renewed his acquaintance with Mr. (afterwards Dr.) Daniel Williams, who had relinquished his pastoral connection with the congregation at Dublin. As he passed to and fro from Ireland to London, he was accustomed to preach in several parish churches; and at Liverpool in particular, where he had accidentally officiated, his preaching was so much approved, that upon the decease of the parish minister, whose place he had supplied, several of the inhabitants expressed their wishes, that they might be allowed to procure for him the living. But this offer, however respectful on their part, his principles would not permit him to accept. In 1689, Mr. Emlyn, being altogether unemployed, was invited by sir Robert Rich, one of the lords of the admiralty, to his residence near Beccles in Suffolk; and he was induced to officiate to a dissenting congregation at Lowestoff, where he continued about a year and a half; though he declined complying with their invitation to undertake the pastoral office. The liberality of his sentiments and conduct, during his abode in this place, served to promote a perfect harmony between the members of the established church and the dissenters. Here he became acquainted with Mr. William Manning, a respectable non-conformist minister in the neighbourhood; and their mutual intercourse led them both to adopt sentiments, with regard to the doctrine of the Trinity, in vindication of which Dr. Sherlock's treatise had just appeared, very different from those which they had hitherto entertained. Mr. Manning became a Socinian; but Mr. Emlyn adopted what has been generally called the Arian opinion, believing the pre-existence of our Saviour, as the Logos, and that by him God had created the material world. To this opinion he adhered through life. Upon the abdication of king James II., the turbulence of Ireland in some degree subsided; and Mr. Boyce urged Mr. Emlyn, to join him in the pastoral care of the dissenting congregation in Wood street, Dublin. After much previous deliberation, he accepted the proposal, and, in 1691, removed to Dublin. Here he soon acquired distinguished reputation as a preacher. His discourses were rational, persuasive, and pathetic; his voice was clear and strong, and his delivery dignified and graceful; the devotional services were conducted with great propriety; controversial subjects were avoided; and all the private duties of a Christian pastor were discharged in an exemplary manner. In 1694, Mr. Emlyn married Mrs. Esther Bury, a widow lady, with a handsome jointure; and he was thus enabled to maintain a respectable appearance. After considerable hesitation and suspense, he determined, when a proper occasion offered, to avow his opinion concerning the doctrine of the Trinity. But before the formal execution of his purpose, he met with various domestic troubles. In 1701, he lost both his son and his wife; the latter affliction deeply wounded his feelings, and led him to that admirable train of meditation, which is pursued in the funeral sermon preached on the occasion, and which was printed under the title of "Funeral Consolations." Soon after he was bereaved of his wife, and whilst his mind was in an unfit state to encounter new conflicts, his opinion concerning the Trinity became the subject of investigation. Dr. Cummins, a physician of Dublin, and a member of his congregation, communicated his suspicions to

Mr. Boyce; and they determined to apply to Mr. Emlyn for a declaration of his real sentiments. Having explicitly avowed his opinion, that the God and father of Jesus Christ is alone the Supreme Being, and that the son derives his excellence and authority from him, he offered to withdraw quietly from the congregation, and thus to prevent the disturbance that was likely to ensue. But this pacific measure was unsatisfactory. Mr. Boyce, in a manner that reflects disgrace on his memory, brought the matter before the Dublin ministers, who, after a candid declaration of his sentiments on the part of Mr. Emlyn, immediately forbade him to preach any more. His congregation, during this precipitate course of proceedings, was never consulted on the occasion. Mr. Emlyn avowed his sentiments to the deacons and principal managers of the church; and after respectfully acknowledging their kindness to him, requested his dismissal. The conduct of his accusers was the cause of much surprize and concern to the congregation, and Dr. Cummins himself regretted the part which he had acted. However, it was at length determined that Mr. Emlyn should retire for an interval to England; and such was the violence of the Dublin ministers, that, notwithstanding the great inconvenience and expence, to which he was constrained to submit, two of their number were deputed to "charge him not to preach any where when he went thither." These persecutors followed him with their letters of accusation to London, and endeavoured to deprive him of the benefits of that candour and charity which he experienced on his arrival. Whilst he remained in London, he published a short account of his case; and after an absence of 10 weeks, he resolved to return to his family in Dublin. In order to obviate the prejudices that were entertained against his person and doctrine, he wrote his "Humble Inquiry into the Scripture account of Jesus Christ, or a short Argument concerning his Deity and Glory, according to the Gospel." He then determined to return to England; but his purpose was prevented by the persecuting spirit of his enemies, who obtained a special warrant from the lord chief justice to seize our author and his books. At first the chief justice refused bail; but afterwards allowed it, when two sufficient persons became bound in a recognizance of 800*l.* for Mr. Emlyn's personal appearance. In the next term the grand jury found a bill against him, in which he was indicted of blasphemy. The trial came on in June 1703; and it was conducted in a manner no less disgraceful and tyrannical than the proceedings of a board of popish inquisitors. The jury were intimidated to deliver their verdict, and to bring in the defendant guilty, for which some of them afterwards expressed their concern. After the verdict was pronounced, the attorney-general moved, that the author might have the honour of the pillory; but sentence was deferred till the last day of the term. In the mean time Mr. Emlyn was committed to the common gaol. Mr. Boyce now began to relent, and used all his interest to prevent the passing of the cruel sentence threatened by the attorney-general. Mr. Emlyn also, in deference to the advice of his friends, wrote a letter to the lord chief justice, which was indited with a spirit, and in a style which ought to have influenced his mind. When he appeared to receive judgment, one of the queen's council moved that he should retract; but Mr. Emlyn would not consent. The lord chief justice, therefore, sentenced him to suffer a year's imprisonment; to pay a fine of 1000*l.* to the queen, and to lie in prison till it should be paid; and to find security for his good behaviour during life. He was given to understand, that though the pillory was due to his crime, this punishment was not inflicted, as he was a man of letters. After sentence was pronounced,

he was led round the four courts with a paper on his breast, to be exposed. For more than a quarter of a year, he was kept a close prisoner in the under-sheriff's house; and after the expiration of this term he was hurried away to the common gaol, where he lay among the prisoners in a close room, filled with six beds, for about five or six weeks; and then he was removed upon his petition, by *habeas corpus*, to the Marshalsea, on account of his health. In this prison he wrote, in 1704, a treatise, entitled "General Remarks on Mr. Boyce's Vindication of the true Deity of our Blessed Saviour." In this state of imprisonment, he remained until the month of July 1705, visited by few of his former friends, and altogether neglected by his savage brethren, the Dublin ministers. Mr. Boyce, indeed, should be excepted; and to his zealous and repeated sollicitations, to the generous interference of Thomas Medlicote, esq., the humane interposition of the duke of Ormond, and the favourable report of the lord chancellor, that the exorbitant fine passed upon him was illegal, his release from confinement was owing. By their exertions the fine was reduced to 70*l.*, which was actually paid into her majesty's exchequer; but the archbishop of Armagh, the queen's almoner, who had a claim of 1*s.* in the pound upon the whole fine, insisted on the whole sum, nor would he extend his charity to a conscientious sufferer till he received 20*l.* by way of composition for the 50*l.* to which the sentence entitled him. During Mr. Emlyn's confinement in the Marshalsea, he constantly preached on Sundays to some of the imprisoned debtors, and several of the lower class of his former hearers. Soon after his release Mr. Emlyn removed to London, where he preached once every Sunday to a small congregation of persons of sentiments similar to his own, but without receiving any salary. Attempts were made to restrain him by Charles Leslie, the famous non-juror, and also by the lower house of convocation, but by the moderation of archbishop Tenison, and the interference of government, they were unsuccessful. Mr. Emlyn's congregation gradually declined by the death of his hearers, and was at length dissolved; upon which he retired to obscurity, and employed himself in vindicating, by various publications, the principles he had adopted; and the cause to which he was devoted. One of his most elaborate productions was entitled, "A Vindication of the Worship of the Lord Jesus Christ, on Unitarian principles," and published in the year 1706. One of his most curious works was published in 1710, and was entitled "The Previous Question to the several Questions about valid and invalid Baptism, lay Baptism, &c. considered, viz. whether there be any necessity, (upon the principles of Mr. Wall's History of Infant Baptism) for the continual use of Baptism among the posterity of baptized Christians." In 1715, he published his "Full Enquiry into the original Authority of the Text, 1 John, v. 7, &c. containing an account of Dr. Mill's evidence from antiquity, for and against its being genuine, &c." In this controversy there appeared, pro & con, several tracts, the titles of which we cannot recite in this place, nor can we mention the various publications of Mr. Emlyn on the subject of the Trinity. In 1719, he published "A true Narrative of the proceedings of the Dissenting Ministers of Dublin, against Mr. Thomas Emlyn, and of his Prosecution, (at some of the Dissenters' Instigation,) in the secular court, &c." Mr. Emlyn, though himself unpopular, had the satisfaction to observe, that the opinion for which he suffered excited attention, and gained advocates, both in England and Ireland. Although none of the dissenting ministers in London could dare to ask him to preach for them, except Mr. Burroughs, and Dr. James Foster, he was

honoured with the esteem and friendship of many persons, distinguished by their station and learning; and particularly by Dr. Samuel Clarke, and Mr. Whiston. Upon the death of Mr. James Pierce of Exeter, about the year 1726, it was proposed to invite Mr. Emlyn to be his successor; but he wished them to decline all thoughts of him, as his advanced age, and increasing infirmities would not permit him to accept the office. The gout had much impaired Mr. Emlyn's constitution, and he at length fell a martyr to it, on the 30th of July, 1743, in the 79th year of his age. A complete collection of his works was made in 1746, and is comprised in two vols. 8vo.; to which are added memoirs of his life, written by his son Sollom Emlyn. His sermons are separately published in one volume.

EMMA, in *Biography*, daughter of Richard II. duke of Normandy, wife of Ethelred king of England, and mother of Edward the Confessor, had a considerable share of power during her son's reign. The duke of Kent, who was jealous of her great ascendancy, and desirous of getting rid of her as a rival, caused her to be accused of several high crimes, to which the king her son too readily listened, and not only deprived her of all those immense treasures which she had amassed, but confined her for life in the monastery of Winchester. Some historians go much farther, and contend that she was accused of murder, and of incontinence with the bishop of Winchester, but Mr. Hume considers such reports, and the story of her being obliged to justify herself by walking over the nine red-hot plough-shares, as the inventions of Monks, and propagated for the sake of exciting the silly wonder of posterity. Bayle, however, gives full credit to the facts, and adds that the king, now sensible of the complete innocence of his mother, and penitent for the sufferings he had inflicted on her, submitted his back to the scourge. Hume. Bayle.

EMMAUS, in *Ancient Geography*, a village of Palestine, 60 furlongs N. of Jerusalem; mentioned, Luke xxiv. 13, as the place whither two of our Lord's disciples retired on the day of his resurrection, and where he joined them in the form of a traveller, and demonstrated to them, that the Messiah was to suffer death and to rise again; and where he discovered himself to them at supper, while he was breaking bread. At this place were hot baths; and a church was erected on the spot where Cleopas, one of the fore-mentioned disciples, stood. Josephus informs us, that Vespasian left 800 soldiers in Judea, to whom he gave this village.

EMMAUS, a city of Judea, 22 miles from Lydda, afterwards called *Nicopolis*, and different from the village of Emmaus, though often confounded with it. Mr. Reland proves these to be different places from the testimonies of Josephus, St. Jerom, the Maccabees, and the Talmudists. In this Emmaus, or Nicopolis, there were hot baths, in which, as the tradition of the inhabitants reports, our Lord washed his feet, and communicated a healing virtue to them. Julian, the apostate, from enmity to Christ, gave orders for stopping up this fountain.—Also, a town near Tiberias, in which were hot waters. Joseph. de Bell. l. iv. c. 1.

EMME, in *Geography*. See EMMENTAL.

EMMELIA, *Εμμελία*, in *Antiquity*, a dance peculiar to tragedy, which had all the gravity and dignity that were suitable to the action then representing, and was designed to inspire the audience with sentiments of compassion and benevolence for the unfortunate and oppressed, with indignation against the guilty, and with the love of virtue, and abhorrence of vice. The happy mixture of noble and elegant con-cords, together with an exquisite modulation in the action of the personages, denoted by emmelia, is strikingly exemplified in that piece of *Æschylus*, in which king Priam offers

a ransom for the body of his son. The chorus of Trojans, prostrate with him at the feet of the conqueror of Hector, and like him uttering, amid their dignified emotions, expressions of grief, fear, and hope, communicate to the soul of Achilles, and those of the spectators, the sentiments with which they are penetrated.

The movements of such a dance as this must have been very solemn and majestic, and have bore a great affinity to the action of an orator; it was the only one, excepting the military dances, that had the approbation of Plato. Mem. Acad. Inscript. vol. ii. p. 160. See DANCE.

EMMELIA, in *Music*, tuneful sounds among the Greeks, such as were fit for melody.

EMMELOORT, in *Geography*, a town in the north part of the island of Schockland, in the Zuyder sea; 10 miles E. of Vollenhove.

EMMENAGOGUES, MENAGOGA, in *Medicine*, are such substances as are understood to possess the power of exciting the menstrual discharge in the female sex.

Both the ancient and modern writers on the *Materia Medica*, but especially the former, mention a great number of medicines, to which they attribute this power, and speak of it with considerable confidence. But the articles, to which an emmenagogue quality has been thus ascribed, have not succeeded in the hands of the physicians of cautious observation in our own times; so that it is now generally admitted, that we are not in possession of a medicine, which has any specific power in stimulating the vessels of the uterus. Dr. Gregory asks, in his *Lectures*, "What effect a medicine, possessed of such a power, could have upon men?" which he seems to consider as an unanswerable refutation of the notion of emmenagogues. But may we not equally disprove the existence of a diuretic medicine, by inquiring what effect such a medicine would produce in animals which have no kidney? Experience, however, amply corroborates the opinion; and the operation of those substances, which have occasioned the catamenia to flow, is explicable on other principles than that of a specific stimulus to the uterine vessels. But it is also to be remarked, that there is great room for deception with respect to the operation of medicines, in restoring or exciting the menstrual discharge; and that the fallacious conclusion of "post hoc, ergo propter hoc," has given a character of efficacy to many medicines, (in all departments of practice, but in this most eminently,) which in truth possess no such power. The catamenia frequently appear spontaneously, after long retention or suppression; and whatever medicine happens to be under administration at that time gains the credit of the cure.

There is an error almost universally prevalent among the women themselves, and sanctioned by gossiping meddlers, that the suppression of the menses is the *cause* of almost every disorder which the female constitution can suffer; and consequently, that its restoration, in these cases, is the most important point to be attended to in their treatment. Now the converse of this position is much nearer the truth. The suppression of the catamenia is most commonly the *effect* of a previously disordered state of the constitution, and will be removed, as a matter of course, when the health in general is restored. Hence, such a suppression is one of the symptoms of almost all chronic diseases, and debilitated conditions of the body: it is sometimes the consequence of the opposite state, of a plethoric or inflammatory diathesis. The remedies, therefore, which possess an emmenagogue power, operate indirectly upon the uterine system, through their effects upon the system at large; and are consequently of opposite qualities, as they apply to two opposite condi-

tions of the constitution: or, they operate locally upon the adjoining parts, and affect the uterus from its contiguity.

The retention of the catamenia in young women, about the age of puberty, is generally connected with extreme debility of the system, often with that morbid change of complexion which designates the green-sickness, or *Chlorosis*, which see. It is in such cases, that preparations of iron, bark, and other tonic medicines, may be deemed emmenagogues, by restoring the general tone of the habit: the chalybeates have been particularly extolled for their emmenagogue powers. But in full florid habits, when the catamenia are suddenly suppressed, laxatives, diaphoretics, and even blood-letting, most effectually contribute to restore the discharge. Many other reputed emmenagogues operate as local stimuli to the contiguous parts: hence aloes, and other warm purgatives, which irritate the lower portion of the intestines, have been celebrated for their emmenagogue powers. Electricity, applied through the pelvis to the hips and back, has sometimes been an efficacious emmenagogue. Savine, castor, the fetid gums, the warm-bath, and pediluvium, may be deemed stimulants to the uterus, as a part of the general system: the efficacy of the warm-bath, or slipper-bath, when employed about the expected period of menstruation, is often very great. Dr. Mead highly extolled the tincture of black hellebore, which, he says, seldom failed in his practice; and he attributed to it such a stimulative power over the blood-vessels, that when it did not produce the menses, he affirms, the blood was driven through other outlets, as from the nose, bowels, &c. But Dr. Home, and many other physicians, have used it largely in vain. Dr. Home attributes some powers to the savine, and much to madder (*rubia tinctorum*); which, however, has appeared to others to be altogether inert. Cullen *Mater. Medica*, vol. ii. Home *Clinical Exper.* p. 377. See AMENORRHOEA.

EMMENDINGEN, in *Geography*, a small town of Germany, in the grand duchy of Baden Durlach, situated on the river Eltz, in the district of Hochberg, the neighbourhood of which produces excellent wine; but it is chiefly remarkable for a fruitless conference, which was held here in the year 1590, between the Roman Catholic and Lutheran divines of Germany. Emmendingen is on the high road from Switzerland to Franckfort, on the Mayn.

EMMENTHAL, one of the finest and richest valleys of Switzerland, in the canton of Aarau, deriving its name from the river Emme, by which it is irrigated. The principal towns are Signau, Trachelwald, Soumifwald, and Braudis. Its cheese is known all-over Europe under the name of "fromage de Gruyeres."

EMMERAN, SAINT, formerly a rich imperial abbey of Germany, in the town of Ratibon. Its possessions form now a part of the territory of the prince primate of the Confederation of the Rhine.

EMMERICH, or EMMERICK, a small town of Germany, in the grand duchy of Berg, situated on the Rhine, in the former duchy of Cleves; 9 miles E. of the town of Cleves, and 24 miles S.E. of Nimeguen. N. lat. 51° 39'. It has a considerable trade with Holland, and was anciently one of the Hanseatic towns. Its origin dates from the year 1247, when it was first surrounded with walls.

EMMELIURE, in the *Manege*, a kind of composition of honey, and other ingredients, used for sprains and shoulder-splaits of horses. See CHARGE.

The word is French, derived from *miel*, honey, which is a part of the composition.

EMMIUS, URBO, in *Biography*, a learned philologist and historian, was born in 1547, at Gretha, a village in

East Friesland, of which his father was the pastor. In his studies he was diligent and remarkably successful. His natural timidity and bashfulness prevented him from undertaking the office of minister; and in 1579, he engaged as master of the school of Norden, in East Friesland, which he conducted with great reputation, till he was harassed by bigots for refusing to subscribe the confession of Augsburg; and at length not only deprived of his salary, but prohibited from teaching. From Norden he went to Leer, where he undertook the same office, to the great injury of his late school. When Groningen associated itself with the United Provinces, and planned the re-establishment of its college, Emmius was chosen its director, with the full power of forming such statutes for its government as he should think proper. In this office he continued 20 years, when the college was erected into an university; and Emmius was appointed professor of history and Greek, in which he gave lectures to a very advanced period of life. He died at Groningen, in 1625, in the 79th year of his age, highly respected by all with whom he was connected; and his memory was so much honoured, that the magistrates, to whom he had been an able counsellor on all important occasions, placed his portrait in the town-house. He published many valuable works on history, chronology, and antiquities: among these are, "Decades Rerum Frisicarum;" "Vetus Grecia illustrata," in three volumes, which is highly esteemed as a valuable summary of the geography, history, polity, &c. of ancient Greece. It is recorded of him in his life, that he was so thoroughly versed in the histories of all kingdoms and countries, that, at the request of his friends, he could at any time, and without previous consideration, speak upon the history of all kingdoms and countries, beginning with any period that might be fixed on, and give a complete detail of all the places, times, and circumstances of persons, as if he had come prepared expressly to explain those histories. Eulogies were pronounced on his memory by Thuanus, Scaliger, Douza, Heinsius, David Chytræus, and others. By Scaliger his history of Friesland is called "divine." Bayle.

EMO, or EMO Inn, in *Geography*, in the Queen's county, province of Leinster, Ireland, has been made a post-town, and is much frequented by travellers, as a convenient stage. Adjoining it is Emo-park, the seat of the earl of Portarlington. Emo is 35 miles S.W. from Dublin, and 5 E. from Maryborough.

EMODI MONTES, or *Emodi Mons*, in *Ancient Geography*, part of a chain of mountains in Asia. Pliny says, that the Emodus, the Imaus, the Paropamisus, and the Caucasus, were connected together; and that the Serres inhabited the country beyond these mountains. Dionysius Periegetes places the springs of the Oxus in the Emodian mountains, and extends this chain as far as the Eastern ocean. The mountains Emodus and Imaus, according to major Rennell, are the mountains which extend from the Ganges, above Sirinagur, to Cashmere: separating the dependencies of Hindoostan from those of Great Thibet. This ingenious geographer suspects Emodus and Imaus to be different readings of the same name; and Emaus or Himaus are, without doubt, derived from the Sanscrit word *Himmalech*, signifying snowy. That vast ridge bears the same name at present; and Pliny (l. vi.) well knew the circumstance. The mountains of Rimola, so called in the Lama's map, to which the territories of Napaul extended, were anciently denominated Emodus; and they are a continuation of the chain between Tassudon and Paridrong.

EMODIA, *Αιμαδία*, of *αίμα*, blood, and *οδός*, tooth, in

*Medicine*, a word used by some authors to express a stupor of the teeth.

EMOLLIENTS, are medicines which, when externally applied, have the power of relaxing or softening the fibres, when too rigid. They have all been supposed to act mechanically, but this may be doubted. The commonest form of emollient is a cataplasm or poultice of bread and milk, or other mucilaginous vegetable matter, applied to the skin as warm as can be borne without pain. The relaxation and consequent ease which warm cataplasms produce is very great; but as none of the materials can be readily absorbed through the cuticle, when unbroken, the emollient effect has with great probability been attributed chiefly, if not entirely, to the relaxing effect of warmth and moisture upon the extreme vessels of the living surface, unconnected with any supposed interposition of moisture between the moving fibres.

The other class of emollients comprehends unctuous bodies of all kinds, when assisted by friction; and as there is no doubt of a considerable absorption taking place in this method, it is not improbable that the fibres may be actually softened, and rendered more flexible by mechanical operation. No comparative experiments have yet been fairly made to decide whether one unctuous body is more penetrating, that is to say, more readily absorbed by the skin, than another; so that, as mere emollients, they all have equal claim to use.

EMOLUMENT, is properly applied to the profits arising daily from an office or employ.

The word is formed of the Latin *emolumentum*; which, according to some, primarily signifies the profits redounding to the miller from his mill; of *molo*, *molere*, to grind.

The patent, or other instrument, whereby a person is preferred to an office, gives him a right to enjoy all the dues, honours, profits, and emoluments, belonging thereto.

In our law-books, emolument is used in a somewhat greater latitude, for profit, or advantage, in the general.

EMOTION, in *Elocution*, a mode of utterance applied to appropriate passages and on proper occasions, expressive of disturbance and agitation in the mind of the speaker, reader, or reciter, and calculated to produce the like disturbance and agitation in the minds of the auditors. Under proper regulation of the judgment, this is one of the highest graces of elocutionary expression; nay, so eminently is it calculated to produce the effects at which the highest species of elocution principally aim, that it may sometimes be said most completely to attain its end, when the judgment of the speaker becomes for a while suspended, or is at least surrendered to its influence and domination. By some, however, it is disputed whether the elocutionist (especially the actor) ought really, (for the most perfect production of the effect desired,) to be under the positive influence of the emotion exhibited, or ought only to imitate, by the strong operation of judgment and recollection, so much of the actual emotion of real life, as appears calculated to excite the general or particular sympathy desired; and the writer of this article remembers an instance in which a public lecturer was much censured by a critical auditor, for having suffered himself to be overpowered by his own emotions, in describing the tragical fate of Virginia, under the tyranny of the Roman decemviri, that the last syllable of the sentence "he saved his honour, but he lost his child," expired in an almost inarticulate sob, and the orator, choked with tears, was unable to proceed any farther. The effect produced was, however, the best answer to this hypercriticism. The orator had already proceeded far enough; for although one person remained cold enough to criticise, a shriek of horror had

run through the audience, one half of whom had burst into tears of sympathy, and some of whom had actually swooned away; overpowered by contagious agitation. So superior is nature and reality, to the boasted mechanism of sophistification and art. Art, however, and the severest exercise of judgment, are necessary both to the actor and the orator, (especially to the latter,) in the direction and regulation of these emotions; that it may be known when, and how far they are to be indulged; the cases being very rare in which it can be safe and proper to throw the reins on the neck of feeling, and leave it to make its way to the goal, by its own independent energies. Emotion is partly expressed by change of time or momentum, in the action of the organs of enunciation, and by different degrees of irregularity in the succession and proportions of the cadences; and partly by the modulations of the voice; the intonations of which become modified by the different character of the passion to be expressed; while, in some instances, a tremulous expression, and in others frequent interruptions and abrupt transitions in the tune, considerably heighten the effect. Two things are principally to be avoided in the pursuit or cultivation of this excellence;—the unrestricted indulgence of such feelings as might hurry into coarseness, indecorous vehemence, or bombast; and that frigid affectation which aims at impression by unnatural or unappropriate tones; extremes, which though they may extort *applause* from “the unskilful,” always disgust “the judicious,” and disappoint completely the legitimate end which genuine emotion must have in view,—the excitement of a correspondent sympathy.

Physiognomical expression, or the play and sympathy of the features, and the language of gesticulation, must not be overlooked: for, as Mr. Sheridan has observed, it is a palpable “delusion,” to suppose, “that by the help of words, alone, we can communicate all that passes in the mind of man. The passions and the fancy have a language of their own, utterly independent of words, by which only their exertions can be manifested and communicated.” Lect. on Eloc.

In the recommendation of these accompaniments of elocution to any but the professed actor, the professor, however, must be aware that he has many and obstinate prejudices to encounter. The dullness and indolence of modern elocutionists having conspired, with other causes, to reduce almost all public speaking, but that of the stage, to one sympathetic monotony of tone, and look, and attitude, the superstition of criticism (mistaking sanction for propriety, and established usage for the law of nature) has raised a sort of hue and cry, against all expression of attitude and feature; as if these were mere theatrical affectations and meretricious artifices.

But this subject will be further pursued under the proper heads GESTICULATION and ORATORY; for the present it is only necessary to observe, that as essential to the perfection of that particular branch of the art, accompaniments of gesticulative and physiognomical emotion are universally admitted to be legitimate portions of the art of theatrical recitation, to the judicious application of which the elocution of the stage is indebted for a considerable part of its effect.

EMOTION, in the *Theory of the Mind*, is applied by Dr. Cogan (*Treatise on the Passions*) to the external marks, or visible changes produced by the impetus of passion upon the corporeal system. Thus he distinguishes it from passion, which denotes the violent impression made upon our minds by the perception of something very striking and apparently interesting, and from affections, which are applicable to the less violent, more deliberate, and more permanent impressions,

by causes which appear sufficiently interesting. The strong impression, says this writer, of vivid sensation, immediately produces a re-action, correspondent to its nature; either to appropriate and enjoy, or to avoid and repel the exciting cause. This re-action he distinguishes by the term *emotion*. The sensible effect produced at the first instant by the cause of the passion greatly agitates the frame; its influence is immediately communicated to the whole nervous system, and the commotions excited in that, indicate themselves both by attitudes and motions of the body, and particular expressions of the countenance. It is alone by these visible effects, that the subject is discovered to be under the influence of any passion; and it is merely by the particular changes produced, or kind of emotion, that we are enabled to judge of the nature of the passion. Thus, although the passion exists prior to the emotions, yet as these are its external signs, they must indicate its continued influence as long as they continue to agitate the system.

Sheridan, in his “*Art of Reading*,” discriminates between ideas and emotions. The former, he says, denote all thoughts which rise and pass in succession in the mind. Emotions signify all exertions of the mind in arranging, combining, and separating its ideas, as well as all the effects produced on the mind itself by those ideas, from the more violent agitation of the passions to the calmer feelings produced by the emotion of the intellect and the fancy. Thought is the object of the one, internal feeling of the other. That which serves to express the former Sheridan calls the language of ideas; and the latter the language of emotions. Words are the signs of the one, tones of the other. Without the use of these two sorts of language, it is impossible to communicate through the ear all that passes in the mind of man.

EMOY, or HIA-MEN, in *Geography*, an island near the S. E. coast of China, within the jurisdiction of the province of Fo-ken, about 15 miles in circumference. The port of Emoy is properly an anchoring-place for ships, inclosed on one side by the island from which it takes its name, and on the other by the main land; but it is so extensive, as to be capable of containing several thousand vessels; and its water is so deep, that the largest ships may lie close to the shore without danger. About a century ago it was much frequented by European vessels; but few visit it at present, as all the trade is carried on at Canton. The emperor keeps here a garrison of six or seven thousand men, commanded by a Chinese general. At the mouth of the road is a large rock, visible several feet above the surface of the water; and three leagues from it is a small island, with a natural arch in the middle which admits light from the opposite side; and hence it obtained the name of the “Perforated island.” The island of Emoy is particularly celebrated on account of the magnificence of its principal pagoda consecrated to the deity “Fo.” This temple is situated on a plain, terminated by the sea on one side, and on the other by a lofty mountain. The front of the edifice is 185 feet in length, and its gate is adorned with figures in relief, the usual ornaments of the Chinese architecture. At the entrance is a large portico, with an altar in the middle, on which is placed a gigantic statue of gilt brass, representing the god “Fo,” sitting cross-legged. Four other statues, 18 feet high, though representing persons sitting, occupy the four corners of the portico. Each of them is formed from a single block of stone, and bears in its hands appropriate symbols; *e. g.* one bears a serpent in its arms, twined round its body in several folds; another has a bent bow and quiver; the two others present, one a kind of battle-axe, and the other a guitar, or some similar instrument. Beyond this portico is an outer

court, having at its four sides four pavilions, terminating in domes, and communicating with one another by a gallery. In one is a bell ten feet in diameter: in another a drum of enormous size, used by the bonzes for proclaiming the days of new and full moons. The two other pavilions contain the ornaments of the temple, and often serve to lodge travellers, whom the bonzes are obliged to receive. In the middle of the court is a large tower, terminating in a dome, with a beautiful stone stair-case winding round it. The dome contains a neat temple, the ceiling of which is ornamented with mosaic work, and the walls covered with figures in relief, representing animals and monsters. The pillars that support the roof are framed of wood, varnished, and on festivals are ornamented with differently coloured flags. The pavement of the temple is formed of small shells, presenting in different compartments birds, butterflies, flowers, &c. The bonzes continually burn incense upon the altar, and keep the lamps suspended from the ceiling always lighted. At the extremity of the altar is a brazen urn, which, when struck, emits a mournful sound, and on the opposite side is a hollow machine of wood, used for the same purpose, which is to accompany with its sound their voices, when they sing in praise of the tutelary idol of the pagoda. The god "Poussa" is placed on the middle of this altar, on a flower of gilt brass, which serves as a base, and holds a young child in his arms; several idols, which are without doubt subaltern deities, are ranged around him, and by their attitudes shew their respect and veneration. Behind the altar is a kind of library, containing books which treat of the worship of idols. Across the court is a kind of gallery, containing 24 statues of gilt brass, representing philosphers, who were the ancient disciples of Confucius. At the end of the gallery is a hall, which is the refectory of the bonzes; and beyond a spacious apartment is the temple of "Fo," to which there is an ascent by a large stone stair-case. This temple is ornamented with vases, full of artificial flowers, and in it are musical instruments, such as we have already mentioned. The statue of this god is seen through a piece of black gauze, which forms a sort of veil or curtain before the altar. The rest of the pagoda consists of several large chambers; the gardens and pleasure-grounds are on the declivity of the mountain, and a number of delightful grottos are cut out in the rock, and afford an agreeable shelter from the excessive heat of the sun. There are several other pagodas in the island of Emoy; one of which is called the "Pagoda of 10,000 stones," which is built on the brow of a mountain, in which there is a like number of little rocks, under which the bonzes have formed grottos and pleasant covered seats. Grosier's China, vol. i.

**EMPALEMENT**, or **IMPALEMENT**, a cruel kind of punishment, whereby a sharp pale or stake, is thrust up the fundament and through the body.

The word comes from the French, *empaler*, or the Italian, *impalare*; or rather, they are all alike derived from the Latin, *palus*, a *stake*, and the preposition *in*, *in*, *into*.

We find mention of empaling in Juvenal. It was frequently practised in the time of Nero, and continues to be so in Turkey.

**EMPALEMENT**, or *Calyx*, in *Botany*, denotes the termination of the cortex, or outer bark of a plant; which, after accompanying the trunk or stem through all its branches, breaks out with the flower, and is present in the fructification in this new form. Its chief use is to enclose and protect the other parts. It has received different appellations, according to the circumstances that attend it; as *Porianthium*, or flower-cup, *Involucrum*, or cover, *Amentum*,

or catkin, *Spatha*, or sheath, *Glume*, or husk, *Calyptra*, or veil, and *Volva*, which see respectively. See **CALYX**.

**EMPAPELLING**, or **IMPANELLING**, in *Law*, signifies the writing and entering into a parchment schedule, or roll of paper, by the sheriff, the names of a jury summoned by him to appear for the performance of such public service as juries are employed in. See **JURY**.

**EMPARLANCE**, or **IMPARLANCE**, *Interlocutio*, or *licentia loquendi*, in *Law*, a desire, or petition, in court, of a day to consider, or advise, what answer the defendant shall make to the action of the plaintiff.

The civilians call it *petitio induciarum*. Kitchen mentions *emparlance general*, and *special*; the first seems to be only that made in one word, or in general terms without any special clause. This is of course where the defendant is not bound to plead the same term; and it is without saving to the defendant any exception, which is always to another term. It is granted to the defendant before he pleads by consent of the court; to see if he can end the matter amicably without farther suit, by talking with the plaintiff:—a practice, which is supposed (Gilb. Hist. Com. Pl. 55.) to have arisen from a principle of religion in obedience to that precept of the gospel "agree with thine adversary quickly, whilst thou art in the way with him." (Matt. v. 25.) It may be observed, that this gospel precept has a plain reference to the Roman law of the twelve tables, which expressly directed the plaintiff and defendant to make up the matter while they were in the way, or going to the prætor;—*in via, rem uti pacant orato*. *Emparlance special*, is where the party requires a day to deliberate, adding these words, "Salvis omnibus advantagiis tam ad jurisdictionem curiæ, quam ad breve et narrationem."

This *emparlance* is had on the declaration of the plaintiff; and it is of use where the defendant is to plead some matters, which cannot be pleaded after a general *emparlance*. (5 Rep. 75.) This special *emparlance* is with a saving of all exceptions to the writ or count which may be granted by the prothonotary; or they may be still *more special*, with a saving of all exceptions whatsoever, which are granted at the discretion of the court. (12 Mod. 529.)

*Imparlance* is generally to the next term; and if the plaintiff amend his declaration after delivered or filed, the defendant may imparl to the next term, if the plaintiff do not pay costs, but if he pay costs, which are accepted, the defendant cannot imparl. Also, if the plaintiff declares against the defendant, but doth not proceed in three terms after, the defendant may imparl to the next term. (2 Lill. Abr. 35.) If the writ be returnable on the last day of term, the defendant is of course entitled to an *imparlance*, but must plead in four days of the next term, provided a rule be given either in a town or country cause. On a declaration delivered of *Hilary*, there may be an *imparlance* to *Trinity* term, if the defendant has not pleaded before; for it is the course of the court to give *imparlance* or declaration till the day of pleading. If a writ be returnable in one term, and the declaration is not delivered before the essoign day of the second term, the defendant is not obliged to plead in the same term, but is entitled to an *imparlance*. (Impey, K. B.) The causes of *imparlance* are as follow. The not delivering a declaration in time is sometimes the cause of *imparlance* of course, and where the defendant's case requires a special plea, and the matter which is to be pleaded is difficult, the court will, upon motion, grant the defendant an *imparlance*, and longer time to put in his plea, than otherwise by the rules of the court he ought to have: if the plaintiff keeps any deed or other thing from the defendant, whereby he is to make his defence, *imparlance* may be granted till the plaintiff delivers

delivers it to him, or brings it into court, and a convenient time after to plead. (Hil. 22 Car. 1. B. R.) There are many cases in which imparlances are not allowed. No imparlance is granted in an *homine replegiando*; or in an assise, unless on good cause shewn; nor shall there be an imparlance in an action of special *clausum fregit*, though it is allowed in general actions of trespass. (Hil. 9 W. III. 3 Salk. 186.) Where an attorney, or other privileged person of the court sues another, the defendant cannot imparl, but must plead presently: if the plaintiff sues out a special original, wherein the cause of action is expressed, and the defendant is taken on a special *capias*, he shall not have imparlance, but shall plead as soon as the rules are out. (2 Lil. 35, 36.) In case of pleadings afterwards, a plea to the jurisdiction may not be pleaded after general imparlance. (Raym. 34.) Dilatory pleas cannot be pleaded after a general imparlance, which is an acknowledgment of the propriety of the action. After imparlance the defendant cannot plead in *abatement*; however, if it appear by the record that the plaintiff hath brought his action before he had any cause, the court *ex officio* will abate the writ. (2 Lev. 197.) Although a special imparlance shall not be allowed the defendant without leave of the court first obtained (R. E. 5 Ann.); yet if the writ be returnable before the last return of any term, and the declaration not filed, and notice given four days exclusive before the end of such term, the defendant is entitled to an imparlance, (R. Trin. 22 Geo. III.) Blackst. Com. vol. iii. Jacob's Law Dict. by Tomlins. Art. *Imparlance*.

Britton also uses imparlance for the conference of a jury upon a cause committed to them.

**EMPASMA**, *Εμπασμα*, from *εμπάσσω*, I sprinkle, in *Pharmacy*, a powder thrown or sprinkled over the body, to correct some ill smell thereof, or to prevent unnecessary sweats.

**EMPASTING**, or **IMPASTING**, a term used in *Painting*, for the laying on of colours thick and bold, or applying several lays of colours, so that they may appear thick. See **COLOURING**.

It is formed of the French, *empâster*, which has the same signification of *paste*, or *pâte*, *paste*.

A painting is said to be well empasted with colours, when the colours are bestowed plentifully, or it is well soaked, and saturated with colours.

The term is also used when the colours are laid distinct, and asunder, and not softened and lost in each other: *e. g.* this head is not painted, it is only empasted.

**EMPATTEMENT**, French, from *empâter*, to thicken, in *Fortification*, a term used by some to denote the same with talus.

**EMPEDOCLES**, in *Biography*, a native of Agrigentum, in Sicily, was a disciple of Telauges, a scholar of Pythagoras, and distinguished for his knowledge in every department of science and philosophy, as a poet, an orator, an historian, and a physician. He adopted the Pythagorean doctrine of the transmigration of souls, and wrote a poem on the subject, which the ancients have highly praised. He stated the history of the different changes which his own soul had undergone during its transmigrations, as follows; it commenced its career in the person of a girl, next appeared in that of a boy, afterwards it animated a shrub, then a bird, a fish, and lastly Empedocles. In the same poem, the title of which was, "On the Nature of Things," he explained his doctrine respecting the elements. He contended that "there were four of these elements, which are at continual war with each other, without the power of destroying each other; and that all bodies were produced

by this conflict." The fragments of his verses, which are dispersed through various ancient writers, have been, in part, collected by Henry Stephens. (In *Poesi Phil.* 1574, 8vo.) This circumstance affords some ground for the opinion of Fabricius, (*Bib. Græc. v. i. p. 466.*) that Empedocles was the real author of that ancient fragment, which bears the title of "The golden Verses of Pythagoras." From these fragments his philosophical opinions have been collected. Besides his hypothesis of four elements, the first material principles of which were indefinitely small, round, and similar atoms, he maintained, that it is impossible to judge of truth by the senses without the assistance of reason; which is led, by the intervention of the senses, to the contemplation of the real nature, and immutable essences, of things. The first principles of nature are of two kinds, active and passive; the active is unity, or God; the passive, matter. The active principle is a subtle, ethereal fire, intelligent and divine, which gives being to all things, and animates all things, and into which all things will be at last resolved. Many dæmons, portions of the divine nature, wander through the region of the air, and administer human affairs. Man, and also all brute animals, are allied to the divinity; and it is therefore unlawful to kill or eat animals. The world is one whole, circumscribed by the revolution of the sun, and surrounded, not by a vacuum, but by a mass of inactive matter. In the formation of the world, ether was first secreted from chaos, then fire, then earth; by the agitation of which were produced water and air. The heavens are a solid body of air, crystallized by fire. The stars are bodies composed of fire, they are fixed in the crystal of heaven; but the planets wander freely beneath it. The sun is a fiery mass, larger than the moon, which is in the form of a hollow plate, and twice as far from the sun as from the earth. The soul of man consists of two parts, the sensitive, produced from the same principles with the elements; and the rational, which is a dæmon sprung from the divine soul of the world, and sent down into the body as a punishment for its crimes in a former state, where it transmigrates till it is sufficiently purified to return to God.

The style of Empedocles, if we may believe the account of Aristotle, as quoted by Diogenes Laertius, very much resembled that of Homer; it was extremely energetic and enriched with metaphor, and every variety of poetical figure. His talents drew upon him the eyes of all Greece: his verses were sung at the Olympic games, with those of Homer, Hesiod, and the most famous poets; and at the games, and on all other public occasions, he is said to have been himself the most attractive part of the spectacle, so anxious were the people to behold him. He was greatly distinguished too as an orator, and is said to have been the first of the philosophers who gave lessons on rhetoric in Sicily. He usefully employed this talent of oratory in reforming the licentious manners of the Agrigentines, whom he reproached "for pursuing pleasures, with as much eagerness as if they were to die before to-morrow; and for building houses as if they believed that they should live for ever."

Empedocles was likewise celebrated as a physician, and wrote a poem "On Medicine," consisting of six hundred verses. In this work he is said to have boasted, that he was able not only to cure diseases, but also to drive away old age, and even to restore the dead to life; and to have intimated that the sick would hereafter invest him with divine honours. Pliny affirms that he succeeded in restoring a female, who had lain thirty days, without any signs of respiration: and

Paufanias, one of his disciples, and a physician, wrote a treatise respecting the disease and recovery of this woman, whom he termed *ἀπιος*. He was greatly skilled in music, which, after the example of Pythagoras, he employed as a remedy, not only against the diseases of the mind, but even against those of the body. Being lodged in the town of Gela, with his friend Auchitus, he was informed that a young man in a great rage was determined to kill this friend, who had sentenced his father to capital punishment. Empedocles endeavoured to calm his mind by persuasive discourse; but his eloquence producing no effect, he took his lyre, and combined its melodious sounds with the flowing numbers of poetry; and so employed the modulations, which made the greatest impression on the heart of the young man, that by degrees he was entirely softened, and afterwards became his constant disciple. As a physician, he is related to have been eminently serviceable to his country on many occasions. He paid great attention to meteorology, and not only predicted storms, but proposed remedies against their effects. He counteracted the blighting influence of the Etesian winds, by constructing walls in the narrow passages of the mountains, through which they blew, and occasioned sterility in the neighbouring land: hence, according to Jamblichus and Diogenes Lærtius, he was called *Alexanemos* and *Colyfanemos*, or repeller of the winds. Pliny relates that he allayed a pestilence at Agrigentum, by means of fumigation (*ignium suffitu*); and Plutarch mentions another instance, in which he suppressed a plague, which raged with extreme violence and fatality, by closing an aperture or chasm of the earth, in the vicinity of the mountains, from which he alone observed that pestilential effluvia issued.

For these various services to his country, the Agrigentines offered him the government; which he refused, preferring a philosophical tranquillity to regal honours. He is said, by some of his historians, to have been ever generous, humane, and moderate, and ready at all times to stand forth as the declared enemy of tyrants; and to have vigorously pursued all those who seemed to aspire at the sovereign power. An anecdote is handed down to us in confirmation of this fact. A citizen of Agrigentum having invited him home to supper, and the hour of the repast being arrived, he inquired why it was not served up; "because," said the host, "we wait for the minister of the council." At length this officer appeared, and he was made master of the feast; during which he gave himself so many insolent airs, that Empedocles began to suspect that some secret project was concerted between the master of the feast and his inviter, with a view to re-establish the tyranny. The suspicion was but too well founded. The philosopher next day citing the two persons before the council, they were condemned to death.

A very different character, however, is ascribed to Empedocles by many other writers. He is said to have conducted himself with the utmost pride and haughtiness towards his fellow-citizens, and to have aspired to divine honours; walking pompously about the country, and through the cities, habited like the gods, and seeking the plaudits of the people. He wore a golden crown on his head, with Delphic chaplets in his hands, and brazen sandals on his feet, and was clothed in a robe of purple and gold, his hair being long and flowing.

The accounts of his death are not less various and contradictory. Some authors affirm, that thinking to pass himself for a deity, and to persuade the people that he had been taken directly up into heaven, he ascended *Ætna* in the night, and threw himself head-long into the burning

crater of the mountain, imagining that his death would remain for ever concealed from mortals; but that the treacherous mountain threw up one of his brazen sandals, and thus exposed the folly of the visionary, who disdained to be thought man.

" — Deus immortalis haberi

Dum cupit Empedocles ardentem frigidus *Ætnam*  
Influit." Hor. Ars Poet. v. 465.

Others, however, admitting that he perished in mount *Ætna*, assert that, impelled by his passion for the study of nature, he resolved to examine the crater of that volcano, and that having ventured too far, he accidentally fell into the burning gulf. Some authors, again, have affirmed, that he broke his leg, by falling from a chariot, which brought on a disease that proved fatal. Others pretend that he terminated his own existence, some say by throwing himself into the sea, and some by strangulation with a rope: while others maintain that he died a natural death, at the age of 77 years. But the most commonly received opinion, notwithstanding these contradictions, is, that this philosopher, being extremely advanced in years, accidentally fell into the sea, and was drowned, about 44 years before Christ, or in the 84th Olympiad. Timæus relates, that, towards the close of his life, Empedocles went into Greece, and never returned, and on this account, the exact time and manner of his death remain unknown. According to Aristotle, he died at the age of 60 years. Some writers make a distinction between Empedocles the philosopher, and another who was a poet. Castellani, upon what authority we know not, states that Empedocles, the philosopher and poet, was the son of Meto, and grandson of Empedocles, who was an excellent poet.

A statue was erected to the memory of Empedocles at Agrigentum. See Castellani Vit. Medicor. Illust. Mângeti Bibliotheca Scriptor. Med. Haller. Bibl. Med. Pract. Dict. Historique. Brucker's Hist. Philos. by Enf. vol. i.

EMPERESS, EMPRESS, *Imperatrix*, the feminine of emperor; the wife or widow of an emperor; or a princess who is the supreme ruler of an empire in her own right.

EMPERESS, is also used in the *Ancient French Poetry*, for a particular kind of rhyme, thus denominated by way of excellence.

The "rhime emperiere" was a sort of crowned rhyme, wherein the syllable that made the rhyme was immediately preceded by two other like syllables of the same termination, which made a kind of echo, called the *triple crown*; and which, to the shame of the nation, (as some of their late authors express it,) their best ancient poets took for a wonderful beauty and excellence.

Fa. Mourgues, in his treatise on French poetry, gives us an instance very proper to raise contempt of the miserable taste of that age, which knew no way of expressing that the world is impure, and subject to change, so excellent, as by saying,

" Qu'es tu qu'un imonde, monde, onde."

EMPEREUR, CONSTANTINE, L', in *Biography*, a learned divine, was a native of Holland, where he took the degree of doctor of theology, and became distinguished in oriental literature and Jewish antiquities. He was professor of theology and Hebrew at Harderwyck during eight years, and then was appointed professor of Hebrew at Leyden in 1627. He died in 1648, a short time after he had been appointed theological professor at Leyden. He obtained the character of a zealous defender of the Christian religion,

religion, against the objections of the Jews. He was the friend of the most learned men of his age, *viz.* of Heinſius, Buxtorf, &c. and offered to ſuperintend an impreſſion of their Talmudical dictionary in Holland. His works were chiefly theological, and highly eſteemed by his contemporaries. *Moreri.*

EMPERICHORESIS. See CIRCUMINCESSION.

EMPEROR, as far as this word denoted formerly the head of the German empire. See GERMANY.

EMPEROR, *Imperator*, among the *Ancient Romans*, ſignified a general of an army; who, for ſome extraordinary ſucceſs, had been complimented with this appellation. It was emphatically beſtowed by the ſoldiers, when, on the field of battle, they proclaimed their victorious leader worthy of that title. When the Roman emperors aſſumed it in that ſenſe, they placed it after their name, and marked how often they had taken it. Thus Auguſtus having obtained no leſs than twenty famous victories, was as often ſaluted with the title emperor; and Titus was denominated emperor by his army, after the reduction of Jeruſalem. See AUGUSTUS and TITUS.

Afterwards it came to denominate an abſolute monarch, or a ſupreme commander of an empire; a Roman emperor, &c. In this ſenſe Julius Cæſar was called emperor, and the title deſcended with the dignity to Octavius Auguſtus, and the ſucceeding emperors.

In ſtrictneſs, the title emperor does not, and cannot add any thing to the rights of ſovereignty; its effect is only to give precedence and pre-eminence above other ſovereigns; and as ſuch, it raiſes thoſe inveſted with it to the ſummit of all human greatneſs.

The emperors, however, pretend, that the imperial dignity is more eminent than the regal; but the foundation of ſuch prerogative does not appear: it is certain, the greateſt, moſt ancient, and abſolute monarchs, as thoſe of Babylon, Perſia, Aſſyria, Egypt, Macedonia, &c. were called by the name of *kings*, in all languages, both ancient and modern. See KING.

It is diſputed, whether or not emperors have the power of diſpoſing of the regal title. It is true, they have ſometimes taken upon them to erect kingdoms; and thus it is that Bohemia and Poland are ſaid to have been raiſed to the dignity; thus alſo, the emperor Charles the Bald, in the year 877, gave Provence to Boſon, putting the diadem on his head, and decreeing him to be called *king*, “*Ut more priſcorum imperatorum regibus videretur dominari.*” Add, that the emperor Leopold erected the ducal Pruſſia into a kingdom, in favour of the elector of Brandenburg; and though ſeveral of the kings of Europe reſuſed for ſome time to acknowledge him in that capacity, yet by the treaty of Utrecht, in 1712, they all concurred.

In the Eaſt, the title and quality of emperor are more frequent than they are among us; thus, the ſovereign princes of China, Japan, Mogul, Perſia, &c. are all emperors of China, Japan, &c.

In the year 1723, the czar of Muſcovy aſſumed the title of emperor of all Ruſſia, and procured himſelf to be recognized as ſuch by moſt of the princes and ſtates of Europe. See RUSSIA.

In the Weſt, the title has been a long time reſtrained to the emperors of Germany. The firſt who bore it was CHARLEMAGNE, who had the title emperor conferred on him by pope Leo III. though he had all the power before. His empire, however, was of no long duration. When the German branch of his family became extinct, the Germans exerciſed the right inherent in a free people, and, in a general aſſembly of the nation, elected Conrad count of

Franconia emperor. After him Henry of Saxony, and his deſcendants, the three Othos, were placed, in ſucceſſion, on the imperial throne, by the ſuffrages of their countrymen: the extenſive territories of the Saxon emperors, their eminent abilities, and enterpriſing genius, not only added new vigour to the imperial dignity, but raiſed it to higher honour and pre-eminence. (See OTHO.) But while the emperors, by means of new titles and new dominions, gradually acquired additional authority and ſplendour, the nobility of Germany went on at the ſame time extending their privileges and juriſdiction. Upon the whole, the imperial prerogatives were formerly much more extenſive than they are at preſent. At the cloſe of the Saxon race, A.D. 1024, they exerciſed the right of conferring all the great eccleſiaſtical benefices in Germany; of receiving the revenues of them during a vacancy; of ſucceeding to the effects of inteſtate eccleſiaſtics; of confirming or annulling the elections of the popes; of aſſembling councils, and of appointing them to decide concerning the affairs of the church; of conferring the title of king on their vaſſals; of granting vacant ſiefs; of receiving the revenue of the empire; of governing Italy as its proper ſovereigns; of erecting free cities, and eſta bliſhing fairs in them; of aſſembling the diets of the empire, and fixing the time of their duration; of coining money, and conferring the ſame privilege on the ſtates of the empire; and of adminiſtering both high and low juſtice within the territories of the different ſtates. But in the year 1437, at the period of the extinction of the emperors of the families of Luxemburgh and Bavaria, they were reduced to the right of conferring all dignities and titles, except the privilege of being a ſtate of the empire; of *preces-primaria*, or of appointing once during their reign a dignitary in each chapter, or religious houſe; of granting diſpenſations with reſpect to the age of majority; of erecting cities, and conferring the privilege of coining money; of calling the meetings of the diet, and preſiding in them.

In the one period, the emperors appear as mighty ſovereigns, with extenſive prerogatives; in the other, as the heads of a confederacy, with very limited powers. The revenues of the emperors decreaſed ſtill more than their authority. The early emperors, particularly thoſe of the Saxon line, beſides their vaſt patrimonial or hereditary territories, poſſeſſed an extenſive domain both in Italy and Germany, which belonged to them as emperors. Italy belonged to the emperors as their proper kingdom; and the revenues which they drew from it were very conſiderable. But the firſt alienations of the imperial revenue were made in this country. The Italian cities, having acquired wealth, and aſpiring at independence, purchaſed their liberty from different emperors. Many diſtricts, poſſeſſed by the emperors, which were intermixed with the eſtates of the dukes and barons, were ſeized by the nobles, during the conteſts that took place between the emperors and the court of Rome. The emperors were alſo almoſt entirely robbed of their caſual revenues; the princes and barons appropriating to themſelves taxes and duties of every kind, which had been uſually paid to them. From the reign of Charles IV., whom Maximilian called the peſt of the empire, the emperors were reduced to the neceſſity of depending entirely on their hereditary dominions, as the only ſource of their power, and even of their ſubſiſtence. Pfeffel Abregé de l'Hiſt. d'Allem.

One principal cauſe of the degradation of the emperors was the aggrandizement of the clergy. The popes, before the firſt period above mentioned, A.D. 1024, had been dependent on the emperors, and indebted for their power

as well as dignity to their beneficence and protection. But they afterwards began to claim a superior jurisdiction; and in virtue of authority, which they pretended to derive from heaven, tried, condemned, excommunicated, and deposed their former masters. Pope Gregory VII. combined political discernment and sagacity with his presumption and violence; and commenced his rupture with Henry IV. upon a pretext that was popular and plausible. He complained of the venality and corruption with which the emperor had granted the investiture of benefices to ecclesiastics. All the censures of the church were denounced against Henry; and the most considerable of the German princes and ecclesiastics were excited to take arms against him. So successful was the court of Rome in inflaming the superstitious zeal, and conducting the factious spirit of the Germans and Italians, that an emperor, distinguished not only for many virtues, but possessed of considerable talents, was at length obliged to appear as a supplicant at the gates of the castle in which the pope resided, and to stand there three days, bare-footed, in the depth of winter, imploring a pardon, which was at length obtained with difficulty. This act of humiliation degraded the imperial dignity. Nor was the depression momentary. The contest between Gregory and Henry gave rise to the two powerful factions of the Guelfs and Ghibellines; the former of which supporting the pretensions of the popes, and the latter defending the rights of the emperor, kept Germany and Italy in perpetual agitation during three centuries. A regular system for humbling the emperors, and circumscribing their power, was formed and uniformly adhered to during that period. The decline of the imperial authority may partly be ascribed to the change which took place with regard to the mode of their election. During a long period, all the members of the Germanic body assembled, and chose the person whom they appointed to be their head; but amidst the violence and anarchy which prevailed for several centuries in the empire, seven princes, who possessed the most extensive territories, and who had obtained an hereditary title to the great offices of the state, acquired the exclusive privilege of nominating the emperor. This right was confirmed to them by the golden bull; the mode of exercising it was ascertained; and they were dignified with the appellation of *Electors*. These electors, by their extensive power, and the distinguishing privileges which they possessed, became formidable to the emperors, with whom they were placed almost on a level in several acts of jurisdiction. See *ELECTOR*, and *DIET*.

To the privileges and powers formerly belonging to the emperors, and which have been above enumerated, some have added, 1. That all the princes and states of Germany are obliged to do them homage, and swear fidelity to them. 2. That they, or their generals, have a right to command the forces of all the princes of the empire, when united together. 3. That they receive a kind of tribute from all the princes and states of the empire, for carrying on a war which concerns the whole empire, which is called the *Roman month*. As to the present mutilated state of the German empire, see *ELECTOR* and *GERMANY*.

The kings of France were anciently also called emperors, at the time when they reigned with their sons, whom they associated to the crown: thus, Hugh Capet having associated his son Robert, took the title of emperor, and Robert that of king; under which titles they are mentioned in the history of the council of Rheims, by Gerbert, &c. King Robert is also called emperor of the French, by Helgau of Fleury. Lewis le Gros, upon associating his son, did the same. In the first register of the King's

Charters, fol. 166, are found letters of Louis le Gros, dated in 1116, in favour of Raymond, bishop of Maguelonne, wherein he styles himself "Ludovicus, Dei ordinante providentia, Francorum imperator Augustus." The kings of England had likewise anciently the title of emperors, as appears from a charter of king Edgar: "Ego Edgarus Anglorum basileus, omniumque regum insularum oceani quæ Britanniam circumjacent, &c. imperator & dominus."

We also say the king of England, "Omnem habet potestatem in regno suo quam imperator vindicat in imperio:" whence the crown of England has been long ago declared in parliament to be an imperial crown.

*EMPEROR*, among *Hebrew Grammatians*, is an appellation given to a species of accents serving to terminate a sense completely, and answers to our point. See *ACCENT*.

*EMPEROR* *Bleß*. See *ELECT*.

*EMPETRON*, in *Botany*, a name by which some authors, as Dodonæus, &c. have called the kali or glass wort. Ger. Emac. Ind. 2. See *KALI*.

*EMPETRUM*, from *εμ*, in or upon, and *πετρος*, a rock, or stone, expressing its stony barren places of growth. Linn. Gen. 515. Schreb. 676. Sm. Fl. Brit. 1072. Mart. Mill. Dict. v. 2. Juss. 162. Gært. t. 106. Class and order, *Diocia Triandria*. Nat. Ord. *Ericis affine*, Juss.

Gen. Ch. Male. Cal. Perianth in three deep, ovate, permanent divisions. Cor. Petals three, sometimes more, ovate-oblong, contracted at their base, larger than the calyx, withering. Stam. Filaments three, sometimes nine, capillary, very long, pendulous; anthers erect, short, deeply cloven.—Female. Cal. and Cor. as in the male. Pist. Germen superior, depressed; style short, simple; stigma nine, spreading, a little reflexed. Peric. Berry orbicular, depressed, of one cell, larger than the calyx. Seeds three or nine, ranged circularly, gibbous at the outer edge, angular at the other. The flowers are commonly dioecious, but sometimes the two sexes are found on the same plant, and even both organs united in one flower.

Ess. Ch. Male. Calyx deeply three-cleft. Petals three. Stamens capillary, from three to nine. Female, Calyx deeply three-cleft. Petals three. Stigmas nine. Berry superior, with three to nine seeds.

The species are two.

1. *E. album*. Linn. Sp. Pl. 1450. (*Erica coris folio decima*; Clus. Hist. v. 1. 45. *E. baccifera tenuifolia*; Ger. em. 1381.) "Stem erect." Observed by Clusius on sandy heaths near Lisbon, bearing fruit early in November. He compares the berries, which are white, acid, and transparent, to pearls of an inferior kind. He generally found but three seeds in each, which accords with Gærtner's account of this species. The stems are shrubby, a foot and half high, erect, branched in a determinate order. Leaves ternate, evergreen, linear, obtuse, revolute, smooth above, resembling those of many heaths. Flowers not observed. Berries lateral, solitary, the size of a moderate pea, resembling those of *Mistletoe*.

2. *E. nigrum*. Linn. Sp. Pl. 1450. Sm. Fl. Brit. 1072. Engl. Bot. v. 8. t. 526. (*E. montanum, fructu nigro*; Raii Syn. 444. *Erica baccifera procumbens*; Ger. em. 1383.) "Stems procumbent." Black Crow-berry, or Crane-berry. Plentiful on mountainous heaths in the north of England, as well as in Sweden, Lapland, Denmark, &c. blossoming in May, and ripening fruit in August. It differs from the former in its more humble and procumbent growth, and in having black berries, with nine seeds. Flowers reddish, axillary, plentiful about the tops of the last-year's branches. The fruit has a mild flavour of elderberries,

berries, and "affords sustenance to ptarmigans, grouse, partridges, and even to the hardy highlander himself."

EMPHASIS, in *Elocution*, a term generally, but absurdly, used by modern writers, exclusively in the singular number. "Emphasis," says Mr. Sheridan (Lecture iv.), "discharges in sentences the same kind of office that accent does in words. As accent is the link which ties syllables together, and forms them into words; so emphasis unites words together, and forms them into sentences, or members of sentences. As accent dignifies the syllable on which it is laid, and makes it more distinguished by the ear than the rest; so emphasis ennobles the word to which it belongs, and presents it in a stronger light to the understanding. Accent is the mark which distinguishes words from each other, as simple types of our ideas, without reference to their agreement or disagreement. "Emphasis is the mark which points out their several degrees of relationship," and the rank which they hold in the mind. Accent addresses itself to the ear only; emphasis, through the ear, to the understanding. Were there no accents, words would be resolved into their original syllables: were there no emphasis, sentences would be resolved into their original words. And in this case, the hearer must be at the pains himself, first, of making out the words, and afterwards their meaning: and as this could not be done, without such length of pauses at the end of sentences, and their several members, as would allow him time to revolve in his memory the sounds which have been uttered, it would make the action of listening to discourse laborious and disgustingly tedious. Whereas, by the use of accent and emphasis, words, and their meaning, being pointed out by certain marks, at the same time that they are uttered, the hearer has all trouble saved, but that of listening; and can accompany the speaker at the same pace that he goes, with as clear a comprehension of the matter offered to his consideration as the speaker himself has if the speaker delivers himself well."

It is not very easy to discover what Mr. S. means, (even with his interpretation of the word accent,) when he says, that "were there *no accent*, words would be resolved into their *original syllables*;" since monosyllables, though denied the property of what is here called accent, are nevertheless admitted by Mr. S. and the grammarians in general to be words; and since, as will be shewn hereafter, the ear alone (unassisted by the memory of impressions received through the eye) has even yet (with all the assistance derived from that *poise* and that *percussion* of particular syllables, so absurdly confounded in the popular abuse of the term accent) no possible means of distinguishing polysyllabic words from successive monosyllables, when properly pronounced. Certainly he is not at all more intelligible, when he adds, "were there *no emphasis*, sentences would be resolved into their *original words*;" or again, when he informs us, that "by the use of accent and emphasis, *words, and their meaning*, are pointed out by certain marks, *at the same time* that they are uttered." That shifting the percussion, or varying the poise of similar associations of syllables, will essentially change the meaning even of words in their separate capacity, (as *disser, deser; désert, desért; présent, présént; refusé, refúsé; objet, objét; incense, incensé*, &c. see B. Jonson's Gram.) and still more of such associated syllables as may occasionally be brought together in the composition of sentences, must be readily allowed; and that the sense of *all sentences* would be much obscured by the omission, and of *many* entirely inverted by a transposition of the emphases: but still the words, as words, and their meanings as words, (though not their specific re-

lations to the other words of the sentence,) would be recognized "at the same time they were uttered," whether they were accompanied with emphases or not: and as for what is here misnamed the accent, the *poise* at least must of physical necessity be somewhere placed; and *speech* without it could not be conducted at all. But Mr. S. never seems to have dreamed of submitting either the process or the nomenclature of elocution to physiological or critical analysis. He used the terms of his art as he found them in the works of the grammarians and rhetoricians of modern times; and as their phraseology was all confusion and contradiction, his elucidations were not likely to be very satisfactory. The Lecture on Emphasis, however, is by far the most valuable portion of this work.

"The necessity of observing propriety of emphasis," says he, "is so great, that the true meaning of words cannot be conveyed without it. For the same individual words, ranged in the same order, may have several different meanings, according to the placing of the emphasis. Thus, to use a trite instance, the following sentence may have as many different meanings as there are words in it, by varying the emphasis: "Shall you ride to town to-morrow?" If the emphasis is on *shall*, as, *Shall* you ride to town to-morrow? it implies, that the person spoken to had expressed before such an intention, but that there is some doubt in the questioner whether he be determined on it or not; and the answer may be, Certainly, or, I am not sure. If it be on *you*, as, *Shall you* ride to town to-morrow? the question implies that some one is to go, and do you mean to go yourself, or send some one in your stead? and the answer may be, No, but my servant shall. If on *ride*, as, *Shall you ride*, &c.? the answer may be, No, I shall walk, or go in a coach. If on *town*, as, *Shall you ride to town* to-morrow? the answer may be, No, but I shall ride to the forest. If on *to-morrow*, as, *Shall you ride to town to-morrow*? the answer may be, No, not to-morrow, but the next day."

These observations and illustrations may serve to shew the importance of emphases in general; but they do nothing towards illustrating the specific characteristics of such emphases. Indeed, in all that Mr. S. has said upon this subject, it should seem as if he had no clear conception of any other species of emphasis, than the emphasis of force; and it is evident, indeed, that the conceptions of the generality of readers and reciters, practically, go no farther. Mr. S. does indeed say, in another place, "that emphasis is of two kinds," (surely, then it should have been that emphases are of two kinds,) "simple or complex. Simple, when it serves only to point out the plain meaning of any proposition; complex, when, besides the meaning, it marks also some affection or emotion of the mind; or gives a meaning to words, which they would not have in their usual acceptation, without such emphasis. In the former case, emphasis is little more than a stronger accent, with but little change of tone; when it is complex, besides force, there is always superadded a manifest change of tone. Simple emphasis belongs to the calm and composed understanding; complex, to the fancy and the passions." But the concluding remark sufficiently evinces how little the nature of these varieties was understood by this author, and how imperfectly the terms of his art were defined in his own mind; for it will presently be shewn, that even without any necessity of appeal to the fancy and the passions, a much more complex system of emphases is necessary fully to elicit, and agreeably to illustrate, the sense of many passages. Mr. Cockin, in his "Art of delivering written Language," animadvert upon the want of clearness in this distinction, and upon

## E M P H A S I S.

the apparent confusion between the significant power of emphasis and the various "tones, simply considered, of all the emotions of the mind;" and seems to imagine he has remedied the confusion by contradistinguishing emphases into "emphasis of sense, and emphasis of force;" and Mr. Walker, (*Elements of Elocution*, p. 190.) considers this distinction as having "thrown great light upon this abstruse subject." But as the emphasis of force is most assuredly as indispensable to the full expression of the sense, as any of the other *several* species of emphases, it is very questionable whether this pretended distinction does any thing more than render confusion worse confounded. Mr. Cockin proceeds; "now from the above account of these two species of emphasis it will appear, that in reading, as in speaking, the first of them will be determined entirely by the sense of the passage, and always made alike: but as to the other, taste alone seems to have a right of fixing its situation and quantity." Farther, "since the more essential of these two energies is solely the work of nature, (as appears by its being constantly found in the common conversation of people of all kinds of capacities and degrees of knowledge,) and the most ignorant person never fails of using it rightly in the effusions of his own heart, it happens very luckily, and ought always to be remembered, that provided we understand what we read, and give way to the dictates of our own feeling, the emphasis of sense can scarce ever avoid falling spontaneously upon its proper place." That mere taste has any thing to do with fixing the *situation* of the emphasis of force (whatever it may have to do with its *quantity* or *degree*) we utterly deny; or that, in just reading or recitation, it can be determined by any thing but the *sense* alone. And as for what is said of even the most ignorant person never failing, in common conversation and the effusions of his own heart, in the right application of the *emphasis of sense*, it is true of all the kinds of emphases; for, in spontaneous speaking, all emphases are emphases of sense; and in all other kinds of speaking (reading or reciting) whatever emphases are not so, must be emphases of nonsense. Mr. Walker, indeed, has himself suggested a much more rational species of distinction, and has made some considerable advances towards a just system or theory upon this subject, by drawing a clear line of demarcation between what, perhaps, might very properly have been called the inherent or *grammatical powers* of particular classes of words, and the arbitrary or *significant emphases* of specific words in a sentence. Perhaps had Mr. W. so denominated them, not only his distinctions, so far as they go, might have been rendered more obvious, but the denomination itself would have led him to discover that there are still distinct species of actual emphases, properly so called, which have escaped his observation. He would not then, perhaps, have told us, that "emphasis, in the most usual sense of the word, is that stress with which certain words are pronounced, so as to be distinguished from the rest of the sentence." He would have perceived that such a definition was much too vague to meet even the full signification of the term in popular usage: for no one does in reality apply the term emphasis to the mere grammatical or inherent force that distinguishes, in all distinct and intelligible spontaneous speech, the nouns and verbs above the articles, conjunctions, and prepositions. The term, on the contrary, always supposes some superadded distinction given to a word or words of what description soever, and conferring upon such words a degree of importance in the sentence, beyond what is inherent in their mere grammatical quality. Mr. W. proceeds, "among the number of words we make use of in discourse, there will always be some which are more necessary to be

understood than others: those things with which we suppose our hearers to be pre-acquainted (he might have added, 'or which are necessary only for the mere grammatical connection of the more important words,') we express by such a subordination of stresses as is suitable to the small importance of things already understood; while those of which our hearers are either not fully informed, or which they might possibly misconceive, are enforced with such an increase of stress, as makes it impossible for the hearer to overlook or mistake them. Thus, as in a picture, the more essential parts of a sentence are raised, as it were, from the level of speaking; and the less necessary are, by this means, sunk into a comparative obscurity." This is both just and pertinent, and the simile at the conclusion is even more apposite, than Mr. Walker seems himself to have been aware; for, to pursue the metaphor in elocution as in picture, it is not merely by the force of a line or the depth of a shadow, that all the varieties of emphatic effect are to be expected to be produced. "From this general idea of emphasis," continues Mr. W., "it will readily appear of how much consequence it is to readers and speakers not to be mistaken in it; the necessity of distinguishing the emphatical words from the rest, has made writers on this subject extremely solicitous to give such rules for placing the emphasis as may, in some measure, facilitate this difficult part of elocution; but few have gone farther than to tell us that we must place the emphasis on that word in reading which we should make emphatical in speaking; and though the importance of emphasis is insisted on with the utmost force and elegance of language, no assistance is given us to determine which is the emphatic word, where several appear equally emphatical, nor have we any rule to distinguish between those words which have greater, and those which have a lesser degree of stress; the sense of the author is the sole direction we are referred to, and all is left to the taste and understanding of the reader."

He then proceeds to state with high commendation the above-mentioned distinction of Mr. Cockin, whose definition he quotes as follows: "Emphasis of force," he tells us, "is that stress we lay on almost every significant word: emphasis of sense is that stress we lay on one or two particular words, which distinguishes them from all the rest of the sentence. The former stress," he observes, "is variable, according to the conception and taste of the reader, and cannot be reduced to any certain rule: the latter," he says, "is determined by the sense of the author, and is always fixed and invariable. This distinction, it must be owned," continues Mr. Walker, "is, in general, a very just one, and a want of attending to it has occasioned great confusion in this subject, even in our best writers. Thus, when the emphatical words were to be marked, by being printed in a different character, we find in several of the modern productions on the art of reading, that sometimes more than half of the words are printed in italics, and considered as equally emphatical. The wrong tendency of such a practice," continues Mr. W., "was never pointed out till the publication of the essay above-mentioned;" by the assistance of which Mr. W. professes to endeavour to push his inquiries still farther; "not only to establish the distinction he has laid down, but to draw the line between those two kinds of emphasis, so as to mark more precisely the boundaries of each. To this distinction of emphasis he accordingly adds another, making a distinction of each into two kinds, according to the inflexion of voice they adopt; which, though of the utmost importance in conveying a just idea of emphasis, had never been noticed by any of our writers on the subject." The distinction thus added is

## E M P H A S I S.

that which relates to the application of the rising and falling inflexion, and which, though in reality such inflexions apply not only to emphatic words, but in a smaller or greater degree to all the words and syllables of which language, properly delivered, is composed, (every syllable not delivered in a *monotone*, *i. e.* not lung, having of necessity either an acute, a grave, or a circumflex accent,) is assuredly a distinction of much importance, in what relates to the practical adjustment of the emphasis, and for the comprehension of Mr. Walker's theory, relative to which (imperfect as that theory, perhaps, may be) the student will do well to refer both to the "Elements" and to the "Rhetorical Grammar" of that elaborate professor. "This," says Mr. W., "brings us to a threefold distinction of words, with regard to the force with which they are pronounced; namely, the conjunctions, particles, and words understood, which are obscurely and feebly pronounced; the substantives, verbs, and more significant words, which are firmly and distinctly pronounced; and the emphatical word, which is forcibly pronounced: it is the last of these only which can be properly styled emphasis; and it is to a discovery of the nature and cause of this emphasis that all our attention ought to be directed. And first, we may observe, that if these distinctions are just, the common definition of emphasis is very faulty. Emphasis is said to be a stress laid on one or more words to distinguish them from others: but this definition, as we have just seen, makes almost every word in a sentence emphatical."

Mr. W. then adds, "the principal circumstance that distinguishes emphatical words from others, seems to be a meaning which points out, or distinguishes, something as distinct or opposite to some other thing. When this opposition is expressed in words it forms an antithesis, the opposite parts of which are always emphatical. Thus, in the following couplet from Pope:

'Tis hard to say, if greater want of skill  
Appear in writing or in judging ill.

The words *writing* and *judging* are opposed to each other, and are therefore the emphatical words.

But this describes only the emphasis of antithesis, which is certainly not the only species of emphasis, properly so called, that is requisite to well delivered speech; for words are rendered important by apposition, as well as by opposition; by their relative, and their absolute consideration in the sentence, and by their reflective, as well as their antagonistic meaning, and to ascertain and exemplify all the varieties and circumstances of emphases, were almost to illustrate the whole theory of the actual and practicable melody of speech. The threefold distinction above quoted does, however, furnish a clue to a part of this mazy labyrinth; and Mr. W.'s concluding definition, though imperfect, as excluding some essential classes of emphases, is strictly applicable to the full extent of his view, which was certainly the most comprehensive that had then been taken of the subject. "Emphasis," says he, "when applied to particular words, is that stress we lay on words, which are, in contradistinction to other words, either expressed or understood. And hence will follow this general rule; wherever there is contradistinction in the sense of the words, there ought to be emphasis in the pronunciation of them; the converse of this being equally true, wherever we place emphasis we suggest the idea of contradistinction." Now though it is not true, that all emphasis has an antithesis, either expressed or understood, yet as the emphases of antithesis constitute a very large and material class of these rhetorical distinctions, the following rules may be regarded as highly important. "If the em-

phasis excludes the antithesis, the emphatic word has the falling inflexion; if the emphasis does not exclude the antithesis, the emphatic word has the rising inflexion. The grand distinction, therefore, between the two emphatic inflexions is this; the falling inflexion affirms something in the emphasis, and denies what is opposed to it in the antithesis; while the emphasis with the rising inflexion, affirms something in the emphasis without denying what is opposed to it in the antithesis; the former, therefore, from its affirming and denying absolutely, may be called the strong emphasis; and the latter from its affirming only, and not denying, may be called the weak emphasis."

They who pursue Mr. W. through all his distinctions of simple, double, and triple emphasis, will undoubtedly, upon the whole, be much edified, though even with respect to the application of the inflexions they may not agree with him in every instance. But if Sheridan attempted nothing more than a practical elucidation of the application and misapplication of emphasis, without laying down any general principles, or rules of extensive and perspicuous application, or discriminations of the characteristic varieties of emphases; and if Cockin only suggested without properly defining the differences between the grammatical import, and the emphatic distinction of words; Mr. W. while he has in some instances well defined the principle of the application of the rising, and the falling inflexions to emphatic words, has left it to more recent discovery to define, and to classify the several species of emphases, (properly so called,) and to point out the distinct properties, or actions both of the voice and the enunciation by which those species are to be contradistinguished. "All emphases," it is maintained by the lecturer on the science and practice of elocution, "affect the words upon which they fall in the three predicaments, of time, of tune, and of force, but as some species of emphases require a preponderancy of one, and other species of another of these properties, emphases may properly be contradistinguished into three kinds; emphasis of time, or the condition of words rendered emphatical, by the increased quantity assigned to the respective syllables; emphasis of tune, or the condition of words rendered emphatical, by the distinction of a superior degree of inflexion, or by a higher or lower pitch in the musical scale; and emphasis of force, or the condition of words rendered emphatical by the superior energy with which they are uttered. And the adjustment of these respective varieties of emphases, to their respective occasions, it is contended, is of equal importance with the selection of the proper situations for placing an emphasis at all; since the sense may be as completely perverted, or at least the ear may be as much shocked by inserting the emphasis of force (a very common error in theatrical recitation,) where that of tune, or of quantity was required, as by placing it altogether on a wrong word. To elucidate this system satisfactorily, would require more space than can conveniently be spared, in a general dictionary of the circle of sciences; but as there at present exists no printed copy of the lectures in question, nor any book upon the subject to which the student can be referred, part of a column will not perhaps be misapplied, by being devoted to the subject. The kinds of emphases enumerated are principally as follows. 1. The objective emphasis, or emphasis of import, *i. e.* the stress of voice by which proportionate importance is given to the word or words, conveying the substantive matter, or leading object of the sentence, as "I am desirous of being acquainted with *the nature of Man*." That is to say, "the nature of man is a subject to which I am desirous of directing some enquiry;" an idea which may be expressed either with or without any

reference to any other subject, either as associated or rejected. In which latter case, no antithesis is either expressed or implied, and the simple emphasis of import is expressed, by an increased stress of the voice, thrown upon the whole of the syllables, composing the amalgamated substantive, or compound name of that object, to wit, "the nature of man." 2. Emphasis of antithesis, or that characteristic stress and inflexion of the voice by which the opposition between two ideas, or parts of a compound idea, is pointed out, and emphatically impressed upon the mind. The antithesis may be either expressed or understood. Thus, if the preceding passage be requested with an emphasis upon the word *nature* only, and that emphasis be principally specified by a strong circumflexive accent (that is to say, by a partial increase of quantity and a specific peculiarity of time) I am desirous of becoming acquainted with the *nature* of Man;—the words have changed to a certain degree their signification; an antithesis is understood; and the interpretation becomes "It is not the *history*—it is not the outward *form* and *complexion*, or any other particular incident relative to man, but his general nature, his physical and moral attributes that I am desirous of knowing." Again, if the single word *Man* be rendered emphatic by superadding to the customary energy of the closing poise or final heavy syllable a certain portion of the same species of time, "I am desirous of becoming acquainted with the nature of *man*," will then by another implied antithesis come to signify, "It is not with the nature of stones, and earths, and shrubs, and herbs, and brute animals, that I am desirous of becoming acquainted, but with that of man." Of the direct or expressed antithesis we have an illustration in the following sentence. "It is not with the nature of *Man*, but with the nature of *God*, that I am desirous of being acquainted." Upon this species of emphasis little need be added to what has already been said by Mr. Walker. 3. The emphasis of coincidence, or the level and equal stress of the voice upon two or more words either in the same or different members of a sentence; by which the relationship, agreement, and equal importance of the annexed ideas are indicated: as—"The *stature*, the *form*, and the *complexion* of man, as well as his *moral* and *physical* attributes are parts of his nature; and his *history* must be studied that his nature may be understood." In this instance all the words distinguished by italics demand the emphasis of coincidence: a species of emphasis which is expressed more by its time, or quantity, than either by its inflexion or its force. As this is the species of emphasis that is least obtrusive, it is that which may be used with the greatest frequency and freedom. 4. Complicated emphases. Sometimes all the different kinds of emphases are mingled in one sentence; so that several different words, or pairs of words, require to be discriminated in all the varieties and degrees of time, tune, and force. "It is not the *NATURE* of *Man* that I am desirous of *STUDYING*; but the *LAWS* of *God* that I am *anxious* to *COMPREHEND*." Here *NATURE*, *LAWS*; *Man*, *God*; *desirous*, *anxious*; *STUDYING*, *COMPREHEND*, require to be respectively balanced and coupled in the mind by appropriate responses of quantity, tune, and force; which if the sentence flowed spontaneously would as spontaneously be adjusted in all propriety, but the due application and apportioning of which to written language constitutes one of the most difficult parts of the art of reading.

There is one thing more which it is necessary to observe on the subject of emphasis, and then we have done with this long article. It has been mistakenly supposed, that the distinction of emphasis necessarily belongs to single

words; nay some there are, who, confounding emphasis with mere percussive, would confine it to single syllables; but the fact is, that emphasis (properly so called) belongs not either to the syllabic separation, or grammatical structure of words, but to the idea; and whether the substantive idea be expressed by a simple or by a compound name, the *whole* name of that idea, not a part only of that name, must bear the equal impress of that emphasis:—thus, for example, in the famous reply of the first William Pitt to Mr. Walpole,—“But youth it seems is not my only crime; I have been accused of acting a theatrical part.” Here neither the word *acting*, nor the word *theatrical*, nor the word *part*, taken separately, designates the jut of the accusation, or constitutes the name of the idea included in the accusation: for if we read, “I have been accused of *acting* a theatrical part,” placing the emphasis only on the word *acting*; may it not properly be asked—Why, what would you do with a theatrical part but *act it*? If the emphasis be placed on *theatrical*, “I have been accused of acting a *theatrical* part?”—what part should be *acted*, but one that is *theatrical*?—if upon the word *part* alone—I have been accused of acting a theatrical *part*?—what that is theatrical can be acted but a *part*? The whole latter member of the sentence constitutes therefore the jut or object of the accusation.—“I have been accused?”—(of what?)—*of acting a theatrical part!*” These words therefore constitute, accordingly, the amalgamated substantive, or compound name of the indivisible, accusatory idea, and must receive throughout an equal portion of *objective emphasis*. Not that the syllables are thereby to be rendered equally forcible, or to be otherwise reduced to one monotonous level. They are only to receive one common superaddition of emphatic force; and as independently of such superaddition, they would have differed among themselves in pause, quantity, accent, and grammatical, or inherent force; in all those particulars they will still continue to differ.

Such is the present state of discovery and ascertainment to which enquiries had been conducted upon the subject of emphasis: by which it should seem, that it constitutes an essential part of the theory and practice of the melody of speech; to which we refer the reader; concluding the present article with the following definition. “Emphases consist in the superadditional importance given to particular words or parts of a sentence, by an increased stress, tune, quantity, or force in the pronunciation of such words or parts of a sentence; and by which their relative importance is pointed out, and the contrasts and assimilations of different members of a description, argument, or position, are discriminated to oral perception.” Whether it be possible, or even desirable that a system of notation (the want of which is lamented by Sheridan and others) should be invented and applied to the indication of these varieties, is a question that may belong to the article *NOTATION*; but which shall not be here discussed.

*EMPHATICAL*, is used by the *Ancient Philosophers*, to express those apparent colours which are often seen in clouds before the rising or after the setting of the sun; or those in the rainbow, &c.

These, because they are not permanent and lasting, they will not allow to be true colours; but, since these emphatical colours are light modified chiefly by refractions and with a concurrence of reflections, and some other accidental variations; and since they are the proper objects of sight, and capable as truly to affect it as other permanent colours are, there is no reason for excluding them from the number of true and genuine colours, since all other colours are only modifications of light, as these are.

**EMPHEREPYRA**, in *Natural History*, a genus of siderochita, composed of various crusts or coats, surrounding a nucleus of the same matter and structure with themselves. See **SIDEROCHITA**.

Of this genus we have five species. Hill's Hist. Fossils, p. 532.

**EMPHRACTIC**, in *Pharmacy*, the same with *emiplastic*. The word is formed from the Greek *εμψρακτιω*, I stop.

**EMPHRAXIS**, in *Medicine*, an obstruction in any part.

**EMPHRUE**, in *Botany*, the name given by the people of Guinea to a species of tree, the leaves of which they boil in wine, and give as a great restorative in cases of weakness and decay. Its leaves are exactly of the shape of those of the common mulberry, but they are not indented at the edge. Petiver has thence called it "arbor Guineensis mori folio non crenato." Phil. Trans. N<sup>o</sup> 232.

**EMPHYSEMA**. The common meaning of this word, in *Surgery*, is an inflation of the texture parts, in consequence of air getting out of a breach in the lungs, and passing into the communicating cavities of the cellular substance on the outside of the chest, through another breach existing at the same time in the pleura costalis, or membrane lining the thorax. However, there are some less frequent cases of emphysema, which are not comprehended in the preceding definition, as will be explained in the course of the present article. The term is derived from the Greek *εμψυσαι*, to inflate. Dr. Halliday, in a late ingenious essay on the subject under consideration, describes the following as the symptoms of an emphysema, when the affection proceeds from an injury of the thorax. A constant pain takes place in the side, that has been hurt. At first, the suffering is not increased even by a very full inspiration; but, no great length of time elapses, before a very considerable difficulty of breathing occurs, and the patient complains of a sensation, as if cords were drawn across the chest, and of a peculiar tightness at the scrobiculus cordis. If the part, where the pain and uneasiness were first felt, is now examined, a soft puffy tumour may be noticed, which is so very prominent as to prevent the ribs immediately under it from being felt. This tumour increases very rapidly, and is soon diffused over all the chest; but is particularly conspicuous on the neck, breast, and face. The rapidity, with which it now spreads over the whole surface of the body, is amazing, and, in many places, the skin is elevated several inches from the subjacent bones and muscles. When the swelling has become general, the patient finds it extremely difficult both to expire and inspire; the motion of the extremities is very much impeded, and, indeed, when the skin is considerably elevated, such motion is almost entirely prevented. The integuments crackle under the hand; the skin is much paler than natural, feels cold, and when struck, sounds like a wet drum. The air may, in general, be easily pressed from any part; but it returns to the same place again as soon as the pressure is removed. The respiration is exceedingly laborious, and quick. The patient inspires with a sudden effort, and the air, in passing the epiglottis, makes a peculiar noise. Expiration follows inspiration almost instantaneously, and is performed with a deep sigh, or rather groan. The patient is incapable of lying with comfort on either side of his body, and feels most ease, and breathes best, when sitting half erect in bed. The skin and extremities feel very cold. The pulse is sometimes quick and hard; at other times, it is hard and full; but it can only be felt with some difficulty. The eye-lids are frequently so puffed up that the patient cannot see; the features are very much deformed; and the lips assume a purple, or rather a livid hue. At the beginning of the case there is generally

a short tickling cough, which increases with the other symptoms, so as to become almost incessant. What the patient spits up is generally very frothy and mixed with blood. The tongue is dry, and the patient complains of a constant thirst. The voice becomes very weak, and unless the effused air is speedily let out, so as to reduce the swelling and pressure, the patient dies suffocated. (See observations on Emphysema, 1807.) It is utterly impossible for any one to understand the subject of emphysema, without previously having some idea of the manner in which the function of respiration is naturally carried on. He must at least know, that, in the perfect state, the surface of the lungs always lies in close contact with the membrane lining the ribs, both in inspiration and expiration. The lungs themselves are only passive organs, and are quite incapable, by any action of their own, of expanding and contracting, so as to maintain their external surface constantly in contact with the inside of the thorax, which is continually undergoing an alternate change of dimensions. Every muscle that has any concern in producing an enlargement, or diminution, of the chest, must contribute to the effect of adapting the volume of the lungs to the size of the cavity in which those organs are contained. This must happen while there is no communication between the cavity of the pleura and the external air, and while there is no breach of continuity in the surface of the lungs themselves. In the act of inspiration, the thorax becomes enlarged in every direction, the lungs are proportionally expanded, and the air entering through the windpipe, into the air-cells of these organs, prevents the occurrence of a vacuum. On the other hand, in the act of expiration, certain muscles diminish the capacity of the thorax, and the lungs being of course compressed, a large portion of the air, which had just before been inhaled in the preceding inspiration, is again expelled from the trachea.

The few observations, already made, must render it obvious to every reader, that by the constant continuance of the surface of the lungs in close contact with the inside of the chest, both in its enlarged and diminished state, the air is regularly drawn into, and expelled out of the air-cells of those important viscera. It must also be manifest, that immediately a free and direct opening is made through the skin and muscles into the cavity of the chest, some air must enter through the wound, and insinuate itself into this last situation, on the dimensions of the thorax being enlarged by the action of the muscles of inspiration. The lungs on the wounded side, of course, remain collapsed, and less air is drawn into the trachea, in proportion as a larger quantity accumulates between the inside of the chest and the outside of the lungs. In this manner, the expansion of these latter organs on one side becomes gradually more and more obstructed. A certain part of the accumulated air, it is true, is forced out of the wound again in each expiration; but a larger quantity enters at every inspiration, and the lungs on the injured side become at last quite collapsed.

Cases of this kind, by which we imply wounds, attended with a free and direct opening into the cavity of the chest, can never be attended with any serious degree of emphysema. If the wound be not quite ample and straight, a certain quantity of air, expelled at each expiration, instead of getting out of the external orifice, may undoubtedly insinuate itself into the adjoining cellular substance, and occasion some emphysematous swelling. However, this never spreads, under such circumstances, to any considerable extent.

The emphysema also, abstractedly considered, is never productive of much danger, when there is a free and direct opening into the chest; for it will be presently understood

## EMPHYSEMA:

that the danger, in emphysematous cases, depends on the manner in which the air is confined in the cavity of the chest, so as to produce such a degree of pressure on the mediastinum and diaphragm, as obstructs the function of the opposite lung, and occasions a fatal suffocation. Now the very existence of a free opening removes the possibility of the air accumulating in such a manner in the chest, as to cause any dangerous degree of pressure on the diaphragm and other lung. This latter supports life, while the lung on the wounded side lies quietly collapsed, till the wound in the parietes of the chest has healed, and the air has been absorbed.

The foregoing remarks must make us perceive what wisdom there is in the arrangement, of having the chest divided into two cavities, which have no communication with each other. If things were not so ordained, suffocation would be a common consequence of every large wound, that extended into the chest. Bertrandi informs us, that whenever a free opening is made into each side of an animal's thorax, the lungs collapse, and suffocation is always the consequence.

However, wounds which merely penetrate the chest, without wounding the lungs, are never attended with any considerable degree of emphysema. Whatever emphysematous swelling does arise is also produced by the external air, which passes into the thorax through the wound, in the act of inspiration, and out of the orifice of the injury again, when the patient diminishes the capacity of the chest in expiration.

The cases of emphysema, most apt to be attended with alarming symptoms, interrupted respiration, and an extensive diffusion of air in the cellular substance of the body, are commonly produced by narrow oblique stabs, which penetrate the parietes of the chest, the pleura costalis, and pleura pulmonalis, so as to make an opening into the air-cells of the lungs. Emphysema also frequently assumes the same urgent and dangerous form, in cases of fractured ribs, the sharp spiculae of which, being driven inward, tear the pleura costalis, pleura pulmonalis, and surface of the lungs themselves. The latter instances differ from wounds in the circumstance of there being no breach of continuity in the integuments. We have already explained, that whatever air insinuates itself into the cellular substance, in wounds, which simply enter the chest without injuring the lungs, must be derived from without; that is, it first passes into the thorax through the wound. But when emphysema arises from narrow oblique stabs, which enter the chest and injure the lungs; or when the affection originates from the pleura costalis, pleura pulmonalis, and part of the substance of the lungs being torn by the sharp points of a broken rib; whatever air becomes diffused in the cellular substance, first escapes from the breach in the air-cells of the lungs into the cavity of the thorax, and thence is expelled through the wound, or laceration in the pleura costalis, into the common cellular substance, situated on the outside of this latter membrane. In wounds, which simply enter the thorax, without injuring the lungs, the air passes through the opening, into the cavity of the pleura in inspiration, at the same time, and from the same causes, that the air also enters the lungs through the trachea. Circumstances, however, are exceedingly different, when emphysema arises from narrow oblique stabs, or fractures of the ribs, attended with an injury of the lungs. In the first of these cases the air cannot enter the cavity of the chest in the same manner as it does when there is a free and direct opening made in the parietes of the thorax. In the second instance, (namely, fractured ribs,) there is no external orifice at all. Both

these latter kinds of cases, being also accompanied by a wound of the lungs, are essentially different, in many respects, from such examples of emphysema as proceed from a wound, which only enters the chest without doing any mischief to the lungs. When the surface of these organs is wounded, no sooner does the chest become expanded in the act of inspiration, than some of the air escapes from the breach in the substance of the lungs, gets into the cavity of the pleura, and afterwards insinuates itself, through the opening in the pleura costalis, into the common cellular substance.

We shall next endeavour to make the reader understand more clearly the cause of the air collecting in the chest, and becoming effused in such cases of emphysema as proceed from wounds, or injuries, which cause a breach either in the pleura pulmonalis alone, the pleura pulmonalis and pleura costalis together, or in the integuments, muscles, and pleura costalis, without the pleura pulmonalis being at all concerned. We shall enter into this part of the subject rather fully, because it is by no means well understood by the generality of surgeons, and, without a clear comprehension of it, the practitioner must feel completely in the dark, in regard to the right mode of treating the affection.

Dr. Halliday notices, that the lungs in the thorax have often, and not unaptly, been compared to a bladder in a close pair of bellows; but, if we suppose the bellows to be divided into two compartments, and each of these to contain a bladder, which mutually communicate with each other, and with the external air by means of a tube, which is exactly adapted to the nozzle of the bellows, and which admits the air only into the cavity of the bladders, and not into the space betwixt the bladders and bellows, we shall then have a perfect representation of the mechanical structure of the thorax. The bellows will represent the thorax, divided in the middle by the mediastinum; the bladders will represent the lungs of the right and left sides; and the tube, which communicates with the bladders and the external air, will represent the trachea. The only thing which is wanting to render this mechanical representation perfect is, that the bladders should exactly fill the bellows, so as to leave no air betwixt them and the bellows.

It is evident, says Dr. Halliday, that when we lift up the handle of the bellows, the bladders will be filled by the external air rushing in through the tube, which communicates with both, and that, when we depress the handle, the air will be again expelled. Dr. Halliday conceives that this is exactly the way in which the lungs are filled and emptied in respiration. The cavity of the thorax being enlarged, by the contraction of the diaphragm and intercostal muscles, &c. a vacuum is formed, into which the air rushes through the trachea, and we perform what is called *inspiration*; whereas, by the contraction of the abdominal muscles, and relaxation of others, the cavity of the thorax is diminished, and the air is expelled, or we *expire*.

The bellows and bladders, continues Dr. Halliday, will also serve to illustrate the cases of injury mentioned as giving rise to emphysema, and first as occasioned by the pleura pulmonalis of one side being wounded, or ulcerated. This case is, in many respects, the same as if an opening were made in one of the bladders, and which opening would form a communication with the space betwixt the bellows and bladder on one side. Now, suppose that this takes place while the handle of the bellows is depressed, as soon as the handle is raised, air will rush into the space betwixt the bladder and bellows, and, if you keep the handle up for a little time, the bladder will collapse altogether, and the place which it naturally occupied, when distended, will

## EMPHYSEMA.

now be occupied by the air. If we attempt to force out the air by depressing the handle of the bellows, we shall find that this cannot be done; for there is no direct communication betwixt the bellows and external air; and, as the effused air presses equally on all parts of the collapsed bladder, it cannot escape through it. Dr. Halliday next explains, that by the action of the muscles of inspiration, the pressure is removed from the surface of the wounded lung, and the air, which should have rushed in and distended the lung, now passes through the wound, into the space betwixt the pleura pulmonalis and pleura costalis. In the living body the whole of the air inspired will not be thus effused; but, as it must pass through the lung, it will also at first distend it, more or less, according to the size of the opening in the pleura pulmonalis, and this partial dilatation of the wounded lung will always happen while air continues to be inspired on that side. As soon as expiration begins, the general cavity of the thorax being thereby diminished, the effused air will be compressed against the wounded lung; but none of the air which has escaped can re-enter the lung again, because the whole of the air contained in the lung must be forced out, and the pressure against every part of the collapsed lung being equal, will prevent the effused air from separating any part, so as to make a passage for itself into the trachea. In this manner fresh air is accumulated in the space betwixt the pleura at every inspiration, while none is allowed to escape during expiration, and the quantity accumulated at last will be equal to that which was received into the other lung, during the most powerful inspiration after the accident. Dr. Halliday next notices, that this kind of accumulation of air in the chest has been denominated *thoracic emphysema*, and has been supposed to have sometimes proved fatal, without any more extensive diffusion of the air.

Dr. Halliday afterwards informs us, that when an opening exists both in the pleura pulmonalis and pleura costalis, the same circumstances happen as in the foregoing case, till the lung has collapsed; but, that if the patient now attempt to expire, the injured side of the thorax must continue distended, notwithstanding every effort. However, in general the air makes a way for itself through the cellular membrane, and as the passage of air into the cavity of the thorax, during inspiration, is easier than the return of that which has been already effused into the cellular membrane, this effusion continues to go on with great rapidity, while the patient lives, so as to occasion what has been termed *subcutaneous emphysema*.

The above writer also observes, that in the case of a wound which simply penetrates the chest, without hurting the lungs, if the access of air be more free by the wound than by the trachea, more air will enter during inspiration into the cavity of the thorax than into the lungs; and that if the access of air be, on the contrary, less free, then also less air will enter the thorax than the lungs. However, Dr. Halliday remarks, that in the same proportion as air enters into the lungs, or into the cavity of the thorax, it will likewise be expelled from these cavities during expiration. Hence, air would not accumulate in the thorax, did not the lungs always tend to collapse from their natural gravitation. Perhaps no author has offered a more accurate and spirited description of an emphysema arising from a fractured rib than Mr. John Bell, of Edinburgh. This gentleman remarks, that when a rib is broken, the point of the broken bone is pressed down upon the surface of the lungs, so as to lacerate them. It is often from the slightest and most superficial wound of this kind, that the emphysematous tumour proceeds, the laceration of the lungs ex-

tending to so inconsiderable a depth in the lungs, that it does not even occasion the least spitting of blood, or any other symptom of a deep wound; and Mr. John Bell observes, that if the patient die, the wound cannot be seen even after dissection; but can only be discovered by inflating the lungs. Yet, says this gentleman, the surface of the lungs being touched even in this slight way, the air escapes from them at every inspiration; the air which is then within the cavity of the thorax is of course compressed, so that at the next expiration this compression must force the air either back again into the lungs, or else out of the wound in the parietes of the thorax, and thence among the cellular substance surrounding the broken rib. Thus, observes Mr. John Bell, in every inspiration there is a suction of some air, which is drawn through the wounded lungs, the air expands in the cavity of the thorax, the lung which gave out that air subsides again, and lies almost entirely quiescent, partly from the wound in it, which, like a rent in a bladder, prevents it from being inflated, and partly from the pressure of the air in the cavity, in which there ought to be a vacuum to make the lung expand. Every new inspiration draws more air from the wounded lung, and every new expiration drives more air out into the cellular substance. There is no further outlet for the air, which makes its way forwards, and (to use Mr. John Bell's expression) undermines the common skin with wonderful rapidity. Thus, the emphysematous crackling tumour appears first over the broken rib, or over the wounded point of the thorax; then extends over the whole chest, attended with great oppression of the breathing; then over the neck and face, and filling the eye-lids particularly, so that the eyes are absolutely closed. Next it spreads over the belly, and down the thighs. At last, the private parts become enormously swollen, and no part escapes this tumour, except the palms of the hands and soles of the feet. More air, says Mr. John Bell, is every moment drawn out from the wound of the lungs, and driven under the skin; the patient is every moment more and more oppressed; till, at last, the breathing is quite interrupted, the pulse flags, the extremities grow cold, and the patient, if he be not relieved by some operation, must die.

According to the same writer, the wounded lungs collapse, and continue in this state until the breach in them has healed, which happens in a very few days. From the moment when the lungs are wounded, the use of the wounded lobe is lost, so that if the right lung be the one injured, the breathing is entirely carried on by the left, only half the quantity of air is inspired, and the respiration is attended with difficulty. Mr. John Bell considers this collapse of the injured lung, which must inevitably continue for at least a few days, a chief means of safety, at the same time that it is a cause of distress. He observes, that when the lungs are unfolded their vessels have their full diameter, they hold their full proportion of blood, and, if they were not collapsed, their wounded vessels would be in a condition to emit a considerable quantity of blood. But, the fact is, when one of these organs is wounded, it collapses towards the spine, and can no more be filled than a torn bladder can be inflated. The lung is also oppressed by whatever air or blood may be effused in the cavity of the thorax. The collapse of the lung causes less blood to be extravasated in the chest, and less to be thrown into the bronchiz, which latter kind of hemorrhage is even more dangerous than that which takes place in the cavity of the pleura, because it may not only affect the wounded lung, but obstruct the entrance of air into the other one, so as to produce a fatal suffocation.

## EMPHYSEMA.

Mr. John Bell very judiciously remarks, that, if the injured lung were not to collapse, it would be difficult to conceive, how the breach could ever be healed; for, the air would be continually streaming through the wound, which becoming alternately dilated and contracted, like that of an artery, could never close. However, since the wounded lung lies in a collapsed state, the edges of the wound are in contact with each other. We find by dissection, that a slight effusion of blood, a degree of livor, a swelling, thickening, and inflammation, take place round the wound, and thus, in two days, the breach is closed. The lung becomes again entire, and capable of resuming its functions.

Mr. John Bell also takes notice, that the blast of air, from a wound in the thorax, is often so strong, that at every breath it is capable of extinguishing a candle, and rushes out with a considerable noise. This stream of air, so far from being a sign of wounded lungs, is often most remarkable, when the lungs are absolutely entire. It is a sign of a free and open wound in the chest; but, by no means of wounded lungs; for whether these organs be wounded or not, the air enters so freely by the outward wound, when ample and direct, that there is no vacuum formed to give the lung play, and it must collapse, till the external wound has healed. Wounds of the thorax, therefore, are totally different cases from wounds of the lungs. When the chest has a large free opening made into it, it is (as Mr. John Bell describes) like a pair of bellows, having a large air-hole, which admits the air every time the breast rises; and expels it again as often as the breast falls down. The air is alternately drawn in, and thrown out at every respiration, with a strong blast; but, whatever air issues through the wound, had been drawn in by the wound, and had never passed through the lungs. Hence, when there is a free opening made in the thorax, no vacuum can form so as to lead to the expansion of the lung, and whether entire, or injured, it must be in a collapsed state.

We may be convinced, that the lung, on the side opposite the wound, is adequate to the temporary support of life, by the recollection of several kinds of cases. When a large free opening has been made into the chest by some accident, or by the surgeon's knife, the lungs on the injured side of course collapse; yet, the patient has often been known to live with tolerable ease in this condition, until a perfect recovery has followed. When the right or left lung has been utterly prevented from becoming expanded, in consequence of the pressure of air in emphysema, water in hydroys pectoris, or pus in empyema, the patient has often lived a considerable while in this state, and ultimately got well. Persons have lived so long with disease in the chest, that when they have died, and their bodies have been opened, only a small knob, or tubercle of the lungs on one side, has been found remaining. See Koelpen de Empyemate Observatio, p. 135, 136.

When the lungs are wounded by the point of a broken rib, or when they are injured by a narrow stab in the thorax, the air cannot readily escape from the cavity of the chest, while at every inspiration more and more is drawn out from the lungs, till at last such a quantity accumulates, that it not only oppresses the lung, which is on that side, but by hindering the free action of the diaphragm, and loading the mediastinum, it oppresses the other lung also. In this manner, the breathing becomes gradually more and more interrupted; the pulse sinks; the extremities grow cold; and after great tossing, and undescribable anxieties, the patient dies. All this may happen, even when a part of the air escapes through the breach in the pleura costalis, so as to inflate a

great part of the common cellular membrane of the body. See Discourses on the Nature and Cure of Wounds by John Bell, vol. ii.

From what has been stated, it must be evident, that the emphysematous swelling itself, or, in other words, the diffusion of air in the cellular substance, is a matter of secondary consequence, and, that the great peril of an emphysema depends on the manner in which one side of the chest may become so distended with air, that the pressure produced on the diaphragm, mediastinum, and opposite lung, occasions a fatal interruption of respiration.

However, in cases in which there is a free and open wound in the parietes of the chest, or when the surgeon has made an ample and direct incision into the thorax, the opening, in fact, does not relieve the lung on the same side, but the opposite one, by obviating the pressure of any confined air on it. In the mean while, the lung on the wounded side lies in a collapsed state, till the wound in it has healed.

It is curious to observe, how few of our best modern surgical writers have had accurate notions concerning emphysema. Hewson, Benjamin Bell, and Bromfield, have all fallen into the mistake of supposing it possible to make the wounded and collapsed lung immediately expand again by exhausting the air from the cavity of the pleura. Mr. Bromfield writes, "in case an opening is made between the ribs, and a cannula introduced, whose diameter is larger than the wound of the lungs, the air will be forced out as fast as it escapes from the lungs, therefore the lungs will have room for their expansion," &c. See *Chirurgical Cases and Observations*.

Mr. Hewson observes, "it is natural to suppose, that the wound of the pleura and intercostals may sometimes be too small to suffer the air to get readily out into the cellular membrane, and to inflate it, but may confine a part of it in the cavity of the thorax, so as to compress the lungs, prevent their expansion, and cause the same symptoms of tightness of the chest, quick-breathing, and sense of suffocation, which water does." Mr. Hewson seems to have no idea of the danger of suffocation proceeding from the pressure on the opposite lung, and though he wrote professedly to recommend paracentesis thoracis in these cases, he advises making a small incision, rather than a large one, *lest the air should enter, and hinder the expansion of the lungs*. *Med. Obs. and Inq.* vol. iii.

Mr. Benjamin Bell has undoubtedly run into most strange absurdities in the description in his *System of Surgery*, of plans for expelling the air from the surface of the lungs. "While the wound yet remains open," says he, "let the patient, in a slow gradual manner, make a full inspiration, by which a considerable quantity of the collected air will be discharged. This being done, the skin must be instantly drawn over the *fore*, so as to cover it completely during inspiration; and if the wound be moderately opened during inspiration, the whole quantity will be soon expelled."

In this passage, the author has obviously confounded the words expiration and inspiration, besides displaying ignorance in thinking it practicable to make the collapsed wounded lung rise up again by such proceedings.

The same author remarks: "the other means which we wish to propose for drawing off air from the thorax, is suction; an exhausting syringe may be fitted with such a mouth of ivory or metal, as will allow it to be closely applied over the orifice in the pleura:" He adds, that "as much distress has, on some occasions, ensued from both cavities of the chest being at the same time laid open, it ought never to be attempted." He afterwards imputes the danger, not to the collapse of both the lungs, but to the inflammation likely

## EMPHYSEMA.

likely to arise from the admission of air into the two cavities of the chest at once. The fact is, a free opening made into each side of the chest at the same time would be instantly followed by a collapse of both lungs, and immediate suffocation. There would neither be time for any inflammation to arise, nor for relieving the patient with exhausting syringes.

There is certainly a possibility of making the lungs expand again, by syringes, &c. as soon as the breach in them has healed, or the injured air-cells have been closed with coagulating lymph; but, the propriety and utility of the plan may be justly called in question. The introduction of pipes into the chest cannot be done without irritation; no more air can escape from the lung now the air-cells are closed; what is already effused in the chest will be absorbed, and the lung expand again, in proportion as this is effected; and should the diaphragm and opposite lung suffer dangerous pressure from the large quantity of accumulated air, relief may be derived from making an opening in the distended side of the chest, sufficient for letting out a certain quantity of the confined air. In this instance, a small puncture in the pleura would suffice: the case is not like some others, in which the breach in the lung is not closed, and a very free and direct opening is required, in order to let the air escape from the thorax, as fast as it passes out of the wound in the lung itself. By this step, and no other, can we prevent the spreading of the emphysematous swelling over the whole body, and what is of still higher moment, a perilous degree of pressure on the diaphragm and opposite lung.

Some of the most remarkable cases of emphysema, on record, are related by M. Littré, M. Mery, Dr. Hunter, and Mr. Cheston, in the *Mem. de l'Acad. Royale des Sciences* for 1713, *Medical Observations and Enquiries*, vol. ii, and *Pathological Enquiries*.

With respect to the treatment of emphysema, when the air becomes effused in the cellular substance round a wound, which merely injures the parietes of the chest, the best plan must be to direct the patient to expel as much of the air from the thorax as he can, by making long expirations, the opening being regularly closed when the patient enlarges his chest in inspiration. After getting as much air as possible out of the thorax in this manner, the edges of the external wound may be carefully brought together, and well covered with adhesive plaster, compresses, &c. so as to prevent the ingress of any more air into the chest. The emphysematous swelling can now no longer increase, or, at all events, can only do so as long as whatever air is still in the chest continues unexhausted; and in proportion as it becomes effused, or is absorbed, the lung must expand and resume its function again. In this particular instance, as there is no breach in the lung, the practitioner, if he thinks proper, may endeavour to make the viscus expand again at once, by drawing the air out of the cavity of the pleura with a syringe. However, since all examples of emphysema, which are attended with urgent symptoms of suffocation, are accompanied by a wound or laceration of the air-cells of the lung, we cannot rationally attempt to make this organ immediately expand again by means of suction. The thing is not practicable, because how can we exhaust the air from the chest, as long as more is capable of passing out of the opening in the lung itself. We have likewise already explained, that the collapsed state of the injured lung is the most favourable for the closure of the wound in it, and for the prevention of hemorrhage from its vessels.

In all considerable cases of emphysema, the air, effused in the cavity of the thorax, and common cellular membrane, is derived from a rent, or wound in the substance of the

lungs. The worst symptoms in these instances, as we have already repeatedly insisted upon, depend on the pressure of the air confined in the injured side of the thorax, on the diaphragm, and opposite lung. Both this accumulation of air, and the diffusion of another portion of it in the cellular texture of the body, are entirely owing to one circumstance, *viz.* there being no free and direct passage through which the air can escape outward, as fast as it passes out of the breach in the lung.

The inflation of the external parts with air, a thing which often takes place in an enormous degree, is not itself a case of urgent danger, and, indeed, it is so far a favourable event, as it proves, that the air effused from the lung can escape from the cavity of the pleura in a certain measure. If it could do so with sufficient celerity, no oppression of the diaphragm and opposite lung would be occasioned.

In cases of emphysema, Mr. John Bell recommended the following treatment to be adopted. 1st. Upon observing the crackling tumour begin to form over a fractured rib, small punctures should be made with the point of a lancet, and, if the instrument be carried deeply enough, the air will rush out in an audible manner. As this air was in the thorax before it came into the cellular substance, it is plain, that the thorax is still full, and that the lung of that side is already collapsed and useless, and must continue so for a certain time; that is until the breach in it is closed. The purpose, therefore, of making these scarifications, and especially of making them so near the fractured part, is not to relieve the lungs, but merely to keep the air from spreading more widely beneath the skin.

When the emphysema proceeds from a narrow stab in the chest, the practice should of course be the same, in the same stage of the case, or, in other words, at the period when the external emphysematous swelling is in an incipient state. The two examples resemble each other, inasmuch as the lungs and pleura costalis are wounded in both cases, and the air, which passes through the breach in the pleura, cannot make its way completely outward; but becomes diffused in the cellular membrane.

2dly. If, before the surgeon arrives, the air should have spread to very remote parts of the body, as to the scrotum and down the thighs, it will be easier, says Mr. John Bell, to make small punctures in those parts, in order to let out the air directly, than to press it along the whole body, till it arrives at the punctures, made on the chest, over the wounded part.

3dly. If, notwithstanding free punctures, and pressing out the air in this way, it should be found by the oppression, that either air or blood is accumulating within the cavity of the thorax, so as to oppress not the wounded lung only, which, from the first, is of course collapsed and useless, but, also, so as to oppress the diaphragm and other lung; then a freer incision must be made through the skin and muscles, and a small one in the pleura costalis, in order to let the confined air out of the thorax.

In the course of a few days the wound in the collapsed lung becomes closed by the adhesive inflammation, in which process the breach in the air-cells is shut up with coagulating lymph, and the air can no longer get out of them into the cavity of the chest. The air, which is already there, is alternately absorbed, and the lung, expanding in proportion, resumes its original functions.

Emphysema has been known to arise from the bursting of a vomica, and ulceration of the surface of the lungs; but the air, which escapes in this instance, cannot find its way into the cavity of the thorax, because the inflammation, which precedes the abscess and ulceration of the air-cells,

closes those which are adjacent, and produces an adhesion of the edges of the vomica, or ulcer, to the inner surface of the chest, so as entirely to separate the cavity of the abscess from that of the thorax. We do not know of any example, in which the symptoms imputed to the confinement of air in the chest, originated in consequence of suppuration and ulceration of the surface of the lungs. However, Palfyn, Dr. Hunter, and the author of the article "Emphysema" in the French Encyclopædia, have seen cases, in which emphysema has arisen from abscesses of the lungs, attended with adhesion to the pleura, and ulcerations in the situation of such adhesion. In these cases, the pus having made its way through the pleura, and intercostal muscles, the air escapes also through the same tract, so as to get into the cellular membrane on the outside of the chest.

A certain degree of emphysema has been observed to be occasionally produced by a violent effort of respiration. In the instances referred to, the air is said first to make its appearance about the clavicles, and afterwards to spread over the neck and adjacent parts. The violent efforts of parturition have also been remarked to occasion a similar symptom; but without being followed by any bad consequences. See Medical Communications, p. 176.

In the fourth volume of the Mémoires de l'Académie de Chirurgie, 4to. M. Louis has described an emphysema of this latter sort, which, on account of its cause, and the indication which it affords the practitioner, is highly important. M. Louis had occasion to remark the occurrence in a young girl, who died suffocated, from a bean falling into her wind-pipe, and he considers the kind of emphysema in question as a pathognomonic symptom of such an accident. If this opinion be correct, a knowledge of the circumstance must be of great importance to the practical surgeon; for, if making an opening into the trachea, and attempting to extract the foreign body be delayed, from any doubt concerning the nature of the case, the patient will inevitably die of suffocation. In the case which first attracted the attention of M. Louis to the subject, the emphysema made its appearance on both sides of the neck above the clavicles, and came on suddenly, on the third day after the foreign substance had fallen into the trachea. On examining the body, after death, the lungs and mediastinum were also found to be in an emphysematous state. The retention of air by the extraneous substance produced, according to M. Louis, at every attempt to expire, and, particularly, during the violent fits of coughing, a strong propulsion of this fluid towards the surface of the lungs into the spongy substance of these viscera. The air next insinuated itself into the cellular texture, which unites the surface of the lung to the pleura pulmonalis; and, by communications from cells to cells, it occasioned a prodigious swelling of the cellular substance, between the two layers of the mediastinum. The emphysema increasing, at length made its appearance above the clavicles. This tumefaction of the lungs and surrounding parts, in consequence of air getting into their spongy and cellular texture, is an evident cause of suffocation, and M. Louis observes, that the swelling seems to be so natural an effect of the presence of a foreign body in the trachea, that one can hardly fail to think it an essential symptom, though no author has made mention of it.

An emphysema of the head, neck, and chest, has also been noticed in some typhoid fevers. Dr. Huxham relates an instance of this sort, which took place in a sailor of a scorbutic habit. Medical Observations and Inquiries, vol. iii. art. 4.

Surgical practitioners have frequent occasion to remark the occurrence of a partial emphysema in cases of gangrene.

Emphysema, arising from wounds in the thorax, is very often a case, complicated with large extravasations of blood in the chest, and inflammation of the pleura and lungs; circumstances which must greatly increase the danger, and ought materially to influence the mode of treatment.

The adhesions, so frequently met with between the pleura costalis and pleura pulmonalis, must obviously have the effect of preventing the collapse of the lung, in circumstances under which it would otherwise happen. Were a wound to enter through the middle of any adherent parts, it is plain that no air could find its way out of the lung into the cavity of the thorax.

EMPHYTEUSIS, in the *Civil and Canon Law*, the letting out of poor barren lands for ever, or at least for a long term of years, on condition of the tenants cultivating, meliorating, or mending them, and paying a certain yearly consideration.

The word is formed of the Greek, *εμφυτευσις*, which signifies an *engraftment*, and by metaphor, a *melioration* or *amendment*; for as we only graft trees to mend them, so a man only alienates his land by emphyteusis, on condition of having it amended.

Emphyteuses are a kind of alienations, differing from sales, in that they only transfer the *dominium utile*, the benefits of the ground, not the property, or fee-simple. Among the Romans they were at first temporary, afterwards perpetual.

The twentieth canon of the council of Carthage prohibits the bishops seizing the church's emphyteusis out of the hands of private persons, unless they have been three years without paying rent.

EMPIRE, the territory or extent of land under the command and jurisdiction of an emperor. See EMPEROR.

We say the Roman empire, the empire of the East, the empire of the West, or the western empire, the empire of the Great Mogul, &c.

Antiquaries distinguish between the medals of the *upper* and *lower*, or *bas empire*: the curious only value those of the upper empire, which commences with Cæsar or Augustus, and ends in the year of Christ 270.

The lower empire comprehends nearly 1200 years, reckoning as low as the destruction of Constantinople, in 1453.

They usually distinguish two ages, or periods of the lower empire; the first beginning where the upper ends, *viz.* with Aurelian, and ending with Anastasius, including about 200 years; the second beginning with Anastasius, and ending with the Palæologi, which includes about 1000 years. See MEDAL.

In ancient history we read of four great monarchies or empires, *viz.* that of the Babylonians, Chaldeans, and Assyrians; that of the Medes and Persians; that of the Greeks; and that of the Romans. The first subsisted from the time of Nimrod, the same with Belus, or, as others say, from the time of Ninus, the son of Belus, who founded it in the year B.C. 2059, according to Blair's tables, to Sardanapalus their last king, B.C. 820, and consequently lasted about 1239 years. But chronologists differ much concerning both the commencement and duration of the Assyrian empire. (See ASSYRIA.) The empire of the Medes commenced under Arbaces in the year B.C. 821, and was united to that of the Babylonians and Persians under Cyrus, in the year B.C. 538, and it closed in the 5th year of Darius Codomannus, who was conquered by Alexander B.C. 331. The dominion of Persia, after the death of Darius, was transferred to the Greeks. The Grecian empire lasted only during the reign of Alexander the Great, beginning in the year B.C. 336, and terminating with the death of this conqueror B.C. 323, his conquests being divided

vided among his captains. The Roman empire commenced with Julius Cæsar, when he was made perpetual dictator, after the battle of Pharsalia, in the year of the city 706, 48 years B.C. Some, however, date the commencement of the Roman empire after the battle of Actium, with the first year of Augustus, A.U.C. 723, B.C. 31. The decline of the Roman empire may be considered as principally owing to the despotism of Severus, and the passive obedience of the people. From this period we behold a train of emperors vicious, or impotent, either wilfully guilty, or unable to assert the dignity of their station. The empire itself gradually decayed, harrassed on all sides by powerful invaders, and convulsed by the furious contests of domestic foes. During the reign of Gallienus, 30 pretenders contended for the supreme power, and added all the calamities of civil war to the misfortunes of this devoted empire. The power and influence of the emperors were likewise diminished by the adoption of several colleagues, and by the division of the empire between the two sons of Theodosius the Great, A.D. 295. Arcadius was proclaimed emperor of the East, and Honorius emperor of the West. The western empire contained all Italy, Spain, France, Britain, Germany, Pannonia, and Africa. The eastern empire comprehended Asia the Less, Arabia, Syria, Egypt, Lybia, and the several regions on the Danube. The seat of the empire was removed to Byzantium by Constantine, in the year of our Lord 328: the East and West were then united under the title of the Roman empire, till the Romans proclaimed Charlemagne emperor, A.D. 800. From this epocha the East and West formed two separate empires; that of the East, governed by Greek emperors, commenced under Nicephorus, A.D. 802, or, rather, was continued; but being gradually weakened, terminated under Constantine Palæologus, in 1453, when the Saracens, having subdued Syria, Palestine, Egypt, Cilicia, and other neighbouring countries, and having ravaged the rest of the Roman territories in the East, besieged Constantinople under Mahomet II. and became masters of it. From this period the city has been the imperial seat of the Turkish or Ottoman emperors. The western empire, properly so called, terminated with Augustulus, son of Nepos, A.D. 476, but being revived under Charlemagne, it ended with Charles Le Gros, who possessed all the dominions of Charlemagne, A.D. 887, and it was afterwards known by the appellation of the *empire* or German empire.

EMPIRE, or the EMPIRE, used absolutely, and without any addition, long signified the empire of Germany, called also in juridical acts and laws, the *holy Roman empire*, S. R. I. q. d. *sacrum imperium Romanum*, which constituted what was otherwise called the *Germanic body*.

The empire had its beginning with the ninth century; Charlemagne being created first emperor by pope Leo III. who put the crown on his head in St. Peter's church on Christmas day, in the year 800.

Authors are at a loss under what form of government to range the empire; some suppose it to have been a monarchical state, because all the members thereof are obliged to ask the investiture of their states of the emperor, and to take an oath of fidelity to him.

Others maintain that it was a republic, or aristocratic state, because the emperor could not resolve or determine any thing without the concurring suffrages of the princes. It is added, that if they required investiture from, and swore fealty to him, it was only as head of the republic, and in the name of the republic, and not in his own; just as at Venice, every thing is transacted in the name of the doge. See DOGE.

Lastly, others will have the empire to have been a mo-

nacho-aristocratic state, *i. e.* a mixture of monarchy and aristocracy; because, though the emperor in many cases seemed to act sovereignly, yet his decrees and resolves had no force, in case the state refused to confirm them.

In fine, we should rather choose to call it an aristo-democratic state, because the diet, wherein the sovereignty is lodged, was composed of princes, and the deputies of the cities, and was divided into three orders, or bodies, called *colleges*, *viz.* the college of electors, the college of princes, and the college of cities.

We say, diet of the empire, circles of the empire, fiefs of the empire, princes of the empire, estates of the empire, members of the empire, capitulations of the empire, recessus of the empire, &c. See COLLEGE, DIET, CIRCLE, PRINCE, CAPITULATION, and RECESSUS.

The states or estates of the empire were of two kinds, *mediate* and *immediate*. The *immediate* states were those who held immediately of the empire, whereof, again, there were two kinds; the first, such as had seats and voices in the imperial diet; the second, such as had none. The *mediate* states were those who held of the *immediate*.

The states which afterwards composed the empire were the princes of the empire, the counts of the empire, the free barons of the empire, the prelates of the empire, the princesses or abbesses of the empire, the nobles of the empire, and the imperial cities. For an account of the subsequent changes which this empire has undergone, see ELECTORS, EMPEROR, and GERMANY.

EMPIRIC, in *Medical History*, from the Greek word *ἐμπειρία*, *experience*, an appellation assumed by a sect of physicians, who contended that all hypothetical reasoning respecting the operations of the animal economy was useless, and that observation and *experience* alone were the foundation of the art of medicine.

The origin of this sect is variously stated by different writers of antiquity, who have attributed it to three different persons. The empiric physicians themselves seem to have considered ACRON of Agrigentum, who was a contemporary and rival of EMPEDOCLES, (a pupil of Pythagoras,) in the 70th olympiad, as their founder; and Pliny has asserted the same opinion, in his sketch of the history of medicine. (Nat. Hist. lib. xxix. cap. 1.) "Alia factio, ab experimentis se cognominans *Empiricæ*, cæpit in Sicilia, Acrone Agrigentino, Empedoclis physici auctoritate, commendato." This account of the rise of their sect was maintained by the empirics, in order to obtain the advantage over the rational or dogmatic physicians, who could only date their origin from the time of Hippocrates. But it has been justly remarked, that the physicians, who lived between the time of Æsculapius, and the period, when philosophy and reasoning were applied to medicine, were empirics in fact, though not in name, in consequence of the rude and imperfect state of the art, and cannot be regarded as sectaries, since all were at that time equally empirical.

The best historians refer the establishment of this sect to a much later period; namely, to about the 123d olympiad (A. C. 260); but they are not agreed as to the individual, who first promulgated the doctrine of empiricism. Galen and others have ascribed the origin of the sect to Philinus of Cos, who was a disciple of Herophilus, to whom he was said to be indebted for the first hints of his system. Herophilus was doubtless more attentive to the use of drugs than any of his predecessors, and the empirics directed their views particularly to the discovery of medicines: his numerous discoveries in anatomy likewise led him, and still more his disciples, to question the value of the reasoning of their predecessors, in whose statements of fact they found so much

error, particularly in regard to the structure of the human body. Little, however, is known with certainty respecting this Philinus. Galen quotes him, when writing on the subject of the composition of medicines; and he is said to have written on the nature of plants, and to have commented on the writings of Hippocrates.

Celsus, however, asserts, that Serapion was the first who maintained the doctrine, that the application of reasoning and philosophy to the art of medicine was of no avail, and confined the study of it to practice and experience. (*De Medicina, Pref.*) Serapion was born, and practised medicine at Alexandria, and appears to have been contemporary with Philinus, and the disciples of Herophilus. Galen accuses him of having shewn a contempt for Hippocrates and all his predecessors, in his writings, and of praising himself on all occasions. (*Galen. de subfigurat. Empir. Cap. ult.*) Apollonius, Glaucias, Heraclides of Tarentum, and others of no small note ("non mediocres viri") followed in the steps of Serapion, according to Celsus. Heraclides was one of the most famous of the empirics, and appears to have been the first to employ that valuable substance, opium, in the practice of medicine. Many other names are on record, as belonging to this sect, antecedent and posterior to Heraclides: one of the latest was Marcellus, who lived in the time of Theodosius, and appears to have held some office in the court of that emperor, and was probably therefore a Christian. He has left a treatise on medicines, compiled from various writers, and adapted to the cure of all diseases. The art of medicine, indeed, is indebted to the empirical physicians for many important additions to the *Materia Medica*. With respect to the doctrines of the sect, however, and the principles on which they defended themselves against the dogmatics, we have no other accounts, than those which their adversaries have given, in quoting them with a view to their refutation; all their works upon these topics have perished. Celsus and Galen have stated probably the greater part of the leading points of their tenets.

The *empiric* system, as the term imports, was founded altogether upon *experience*: and those, who belonged to this sect have remarked, that there are three modes by which we learn, from experience, to distinguish what is advantageous and what is prejudicial, in regard to our health. The first of these, and the most simple, arises from *accident*. A person, for example, having a violent pain in the head, happens to fall, and divides a vessel in the forehead; and it is observed that, having lost blood, his pain is relieved. Under the same mode, they include the experience which is acquired by observing the spontaneous operations of the constitution, where no remedy has been applied, as in the following case: a person labouring under a fever, finds his disease mitigated, after a hemorrhagy from the nose, a profuse perspiration, or a diarrhœa. The second mode of gaining experience, is, that, in which something is done by *design*, with a view to ascertain what will be the success of it: as, for instance, when a person, having been bitten by a serpent, or other venomous creature, applies to the bite the first herb that he finds; or when a man attempts to alleviate the symptoms of an acute and burning fever, by drinking as copiously as he is able of cold water; or when a person tries a remedy, suggested to him by a dream, as was frequently done in heathenish times. The third mode of experimenting, is that which the empirics termed *imitative*; which is pursued in cases, when, after having remarked the effects resulting from *accident*, or the spontaneous actions of the system, on the one hand, or from *design* on the other, we make an attempt to accomplish a similar result, by imitating that which was done on those occasions.

This last sort of experience, they contend, is that which peculiarly constitutes the art of medicine, when it has been frequently repeated. They call that *observation*, (*τηρησις*) or *autopsia* (*αὐτοψία*), which each individual sees himself; and use the term *history*, or *record*, (*ἱστορία*) for such observation when committed to writing; that is, the *autopsia*, or personal experience, consists of the observations which each person has made, by his attention to the progress of a disease, whether in regard to its symptoms and changes, or to the remedies employed; while the record is a sort of narration or register of all that was observed by those individuals; which register being completed, (*i. e.* including all the diseases, incident to mankind, and the remedies administered for their alleviation,) the art of medicine would be established with a considerable degree of certainty. But as new diseases sometimes occur, in regard to which neither our personal experience, nor the observations of others, can furnish us with any assistance; and we meet with disorders in particular situations, where the means of relief, sanctioned by experience elsewhere, are not within our reach; we must necessarily have recourse to some other expedient in order to alleviate the sufferings of the patient. The empirics were provided against this particular difficulty, in what they termed a *substitution* of similar means, (*transitus ad simile*, as the Latins have translated it.) This was a new experiment, which they instituted, after having compared one disease with another; or one part of the body with another, of similar structure; or, lastly, one remedy, the nature of which was ascertained by experiment, with another which resembled it. "They tried, for example, in *herpetic* eruptions the remedies which had relieved *erysipelas*; in the diseases of the *arms*, they employed the expedients which had been practised in those of the *legs*; and if they could not procure *quinces*, which are an austere fruit, they used *medlars*, which are not so."

*Observation*, then, *record*, and the *substitution* of similar means, were the three fundamental resources of the art of medicine; according to the empirics; and these were denominated by Glaucias, and others, the *tripod of medicine* (*τρίπους τῆς ἰατρικῆς*.)

There is obviously a great deal of good sense and sound philosophy in this doctrine of empiricism. It points out the true mode of investigating the phenomena of nature, by unwearied experiment; the mode which Bacon laboured to inculcate on the dogmatists, and hypothesis-mongers of his age, which Newton successfully pursued, and which has led the philosophers of later times to the development of that fund of natural knowledge in the sciences of electricity, chemistry, mechanical, and every branch of natural philosophy, by which modern inquiry is distinguished. Compared with this species of investigation, how futile are the speculations, misnamed philosophy in the schools, relative to elements, and essences, which had no existence, except in the imagination of the disputants. For it must be observed, that the ancient empirics did not disregard the dictates of reason and reflection; they only deprecated the application of them to circumstances out of the reach of the senses, and beyond the scope of experiment. Those mischievous principles and practices, which their successors or at least those who have subsequently assumed the title, have made the refuge of ignorance and craft, cannot be alleged against them. This is evident, from the clear and explicit statement of their tenets, which Celsus has transmitted to us: in order to understand which, it will be necessary to attend to the tenets of their opponents, the rationalists or dogmatics, as stated by the same elegant writer.

## EMPIRIC.

The dogmatic physicians maintained the necessity of a knowledge of the four following subjects, in order to be able to cure diseases; namely, 1, of the occult and essential causes of disease; 2, of the evident causes; 3, of the natural actions of the constitution, (or physiology;) and, lastly, of the internal parts, or anatomy. 1. By the *occult* causes, they meant the essential principles of the constitution, or of animal life, under its various conditions of health and disease. And they held, that it was impossible to cure disease, if we are ignorant of the circumstances in which it consists; for that different methods of cure must necessarily be requisite, if a redundancy or deficiency of the *four elements* were the essential cause of disease, according to the hypothesis of some philosophers; or if all disease consist in depravations of the fluids, as was the opinion of Herophilus; or, in disordered respiration, as Hippocrates imagined; or in the passage of the blood into those vessels, which naturally convey air, causing inflammation, and that inflammation exciting the commotion observed in fever, according to the supposition of Erasistratus; or in the obstruction of the invisible pores, by the corpuscles, or atoms, as Asclepiades contended. Against this system of reasoning by hypothesis, beyond the bounds of experimental inquiry, the empirics objected upon the most irrefragable principles. "The attempt," say they, "to scrutinize the occult principles of animal life is fruitless; for 'nature is incomprehensible:' we may ascertain *what* she performs; but *how* she performs it, is to us inscrutable. And the very dissensions among the theorists, and the difference of their accounts of those operations, evince the inscrutability of the subject. They cannot all be right; and why should we believe the statement of one, rather than that of another? Why is Hippocrates more entitled to credit than Herophilus, or Herophilus than Asclepiades? It is obvious that we cannot decide in favour of the opinion of any of them, either from their arguments, or their practical authority; for the arguments of each may be sufficiently plausible and consistent with probability; and their practice may have been equally successful. Indeed this very fact, that physicians of the most opposite theoretical opinions have equally succeeded in restoring health to the sick, proves the independence of the art of medicine upon such disquisitions, and that their success is to be ascribed to their principles of cure having been deduced, not from their speculations about occult essential causes, nor even about the natural actions, but from experiment, from what actual practice had taught them. And such is the case in all other arts. The husbandman and the pilot are not qualified for their respective occupations by theory and discussion, but by practice and experiment. Indeed if reasoning could enable a person to cure diseases, the philosophers would necessarily be the best physicians; whereas, we observe that they are gifted with an abundance of words, but possess very little skill in the art of healing."

2. With respect to the *evident* causes, the dogmatists understood, by that term, the obvious exciting causes of diseases, such as heat and cold, fasting and excess in eating, &c., to the operation of which diseases are often observed immediately to succeed. The empirics admit the utility and importance of attending to these causes; but they contend that, however obvious they may be in many instances, the method of cure is nevertheless not apparent from them, as in ophthalmia, or in a wound; but is ascertained only from experience.

3. The *natural actions* of the body, a knowledge of which the dogmatists maintain to be absolutely necessary to the physician, are those operations of the constitution, which the moderns comprehend under the term physiology; namely,

the nature of respiration; of the concoction or digestion of our food and drink, and its distribution to the different parts of the body, which it nourishes; of the "rise and fall" of the arteries; of sleeping and waking, &c. "Without an acquaintance with the causes of these actions," say the rationalists, "it must be impossible for any one either to suppress incipient diseases, or to cure them when they are completely established." But of all these actions, they deem the digestion of the food the most important, and insist more particularly upon the necessity of its being understood. But in this point again there is great dissension among them: some of them, following the hypothesis of Erasistratus, maintain that the food is concocted by mechanical attrition; others, after Philonicus, the disciple of Praxagoras, assert that digestion is produced by the putrefaction of the food; while others prefer the opinion of Hippocrates, and contend that it is effected by heat. The disciples of Asclepiades, again, affirm that all these hypotheses are idle and futile, for that there is no such thing as concoction, but that the alimentary matter, crude as it is received, is distributed through the whole body. Various as these opinions are, however, they do not dispute the necessity of accommodating the food of the sick to the nature of the function; that is, if the concoction be the result of attrition, then such food should be selected as is most easily broken down; if it be effected by putrefaction, then such food is to be chosen as is most readily putrescent; if by heat, such as most effectually cherishes heat: but if there be no such process as that of concoction, then all these kinds of aliment are improper, and such only should be taken as most completely resists all change. In the same manner, they contend, when a difficulty of breathing occurs, or a morbid degree of sleep or watchfulness, that physician will be the most capable of curing them, who is acquainted with the nature of these functions.

Against this doctrine of the dogmatists, it is evident that the arguments of the empirics were equally conclusive, as against their preceding hypotheses, respecting the occult causes. Their statements, that the very difference of the theories of the dogmatists implies their want of foundation, and that the mode in which nature operates being incomprehensible, we must be content with learning what she operates, are obvious refutations of the futility of these, and indeed of all other hypotheses. "It is of no importance," say the empirics, "to inquire in what manner the distribution of the aliment through the body is accomplished; our only useful inquiry is, what sort of aliment is most easily distributed; and whether digestion is performed by heat or putrefaction, or whether it is not a digestion, but a distribution only, is altogether immaterial, provided we know, from experience, what is most easy of digestion, or the contrary. For," they continue, "the art of medicine, even in its infancy, was not deduced from such hypothetical reasoning, but from experiments. Whence it was observed, among those who were sick, and without physicians, that some, prompted by appetite, had immediately taken food at the beginning of their illness; while others, loathing victuals, had fasted altogether; and that the disease in those who had abstained from food had been alleviated. It would be remarked, too, that some took food in the paroxysm of a fever, others a little before it came on, and others again after its remission; and that it would agree the best with those who ate after the removal of the fever. In like manner, it would be seen, that those who took food freely in acute diseases, suffered an aggravation of their symptoms, while the abstemious would not thus suffer. These and similar circumstances, occurring daily, would be noted

by

by diligent observers; and what had been seen to succeed most generally, that they afterwards prescribed to the sick. Such was the origin of the art of medicine, which, in consequence of the recovery of some, and the death of others, taught us to discriminate the useful expedients from those that were pernicious: and when remedies were discovered by such experiments, then men began to reason about their operation; for the art of employing remedies was obviously not the result of reasoning, but explanatory hypotheses were sought for after the remedies were ascertained.

4. The dogmatists contend, in the last place, that as pains and various disorders attack the *internal parts*, no person, in their opinion, can apply proper remedies to them, when diseased, if he is ignorant of their situation and appearance. Hence, they affirm, that it is necessary to dissect the bodies of the dead, and to examine the viscera and intestines: and they extol the method of Herophilus and Erasistratus, who procured criminals out of prison, by royal permission, and, having dissected them alive, contemplated, even while they were breathing, the parts which nature had before concealed; and remarked their position, colour, figure, size, arrangement, softness, hardness, smoothness, and connection, as well as their processes and depressions, or what is inserted into and received by each part. "For," say they, "when any internal pain occurs, the seat of that pain cannot be ascertained by one who is ignorant of the situation of the viscera and intestines; nor can he cure any part diseased, who does not know what the part is. Besides, if the viscera happen to be exposed in consequence of a wound, if the observer be unacquainted with the natural appearance of each part, he cannot discover what is sound, and what injured or corrupted, and therefore is not qualified to cure that part which is diseased. Even external remedies are applied with much more judgment by one who knows the situation, figure, and size of the internal parts. Nor can it be justly deemed cruel (although it is generally so represented) to put a few guilty individuals to torture, with a view to ascertain means of relief for all the innocent among mankind in all succeeding ages.

To these arguments the empirics reply, that "the preceding doctrines of the dogmatists were only idle and frivolous, but in this there is the addition of excessive cruelty: for what can be more cruel than to cut open the abdomen and chest of living men, and thus to render that benign art, which is the guardian of the health of mankind, the instrument of torture, and that of the most atrocious kind? more particularly when it is considered, that some of the information, which is sought after with so much barbarity, cannot be thus acquired at all, and that the rest may be ascertained without committing murder. For the colour, smoothness, softness, hardness, and other such qualities, are not the same in the body, when dissected, as when it was found: even in bodies that have suffered no violence, these qualities externally are often changed by fear, grief, hunger, indigestion, fatigue, and a thousand other inconsiderable affections. Whence it is still more probable, that the internal organs, which are still more delicate than the external, and to which even exposure to the light is new, must be changed by the severest wounds, or rather by such fatal mangling. Nothing can be more absurd than to suppose that appearances are the same in a dying man, nay, in one already dead, as during life. The abdomen, indeed, may be opened, while a man yet breathes; but no sooner does the knife reach the thorax, and divide the transverse septum, which separates the upper cavity from the lower, (which the Greeks call the *diaphragm*, διὰφραγμα,) than he immediately expires: it is, therefore, the præcordia and viscera of

a dead man which alone the butchering physician brings to his view; and which necessarily have the appearance of the organs of the dead, and not of those of the living. Thus all that is gained by the physician is the opportunity of committing a barbarous murder, and not that of witnessing the condition of the viscera in a living man. If, however, any information can be obtained, as to the appearances of the internal parts while the individual yet breathes, accident often gives the practitioner opportunities for such observation: for it frequently happens that a gladiator in the *arena*, a soldier in battle, or a traveller attacked by robbers, is wounded in such a manner as to expose some internal organ to view; whence a sagacious physician will learn the situation, position, connection, figure, and other circumstances belonging to each, while he is endeavouring to relieve, and not to murder the patient; and thus will acquire, through compassion, that knowledge which others have obtained by the most horrid cruelty. Moreover, it is clear, from the arguments already stated, that it is not necessary to mangle even dead bodies; which, though not cruel, is loathsome to the sight, as are most of the circumstances connected with the dead; and whatever can be learned, respecting the living, may be acquired during the treatment of their diseases and wounds." See Celsus, De Medicina, in Præf.

The concluding observations, which deny the necessity of anatomical knowledge, acquired by the dissection of dead bodies, appear to be the only point in the tenets of the empiric physicians which is liable to dispute. But even in this point, we are satisfied, there is a great portion of truth, so far as relates to the knowledge and treatment of those internal diseases, to which the knife of the surgeon cannot reach; for the knowledge of the appearances and connection of the viscera does not enable us to suggest the practical means of relief, when they become diseased: experience and observation alone, as the empirics contend, have taught us to apply the remedies. See an Essay on the Importance of Anatomical Knowledge to Medicine, in the Edinburgh Med. and Surg. Journal for Jan. 1809.

After having thus stated the doctrines of the empiric physicians, in opposition to those of their opponents, Celsus has subjoined a sensible and judicious criticism respecting the merits of both. But this is not the place to enter more fully into the subject; we must therefore refer those, who wish for the opinion of that classical physician, to his work already quoted.

There is one point, which could not be well introduced under any of the preceding heads, which the dogmatists constantly threw out against the empirics, namely, that *new* diseases occasionally occur, for the cure of which, consequently, practice and experience have afforded no rules or information; whence, they say, it is necessary to investigate their causes, both evident and occult, without a knowledge of which no mortal can find out why one curative expedient ought to be adopted rather than another. But the reply of the empirics to this point is not less accurate and satisfactory than in the preceding parts of the dispute. "New diseases," they say, "requiring new remedies, seldom if ever occur; but if any unknown disorder should appear, the physician would not require the hypothetical doctrines about occult causes to direct him in his method of treatment: he would immediately observe to what known disease it was most nearly allied in its nature and symptoms, and employ the remedies which experience had shewn to be successful in the similar malady; and by such resemblance he would be able to discover a proper remedy." Celsus.

It is evident, then, that both the dogmatic and empiric physicians appealed to experience, and that neither excluded altogether the dictates of reason and reflection. The principal difference in their tenets appears to have consisted chiefly in this: that the empirics reasoned only from the facts ascertained by observation, without attempting to explain their essential and inscrutable nature by hypotheses; and that the latter speculated upon the mode and nature of every action and phenomenon in the animal body, and took these speculations as the basis of their reasoning:—an error in the investigation of nature, which, as we have before said, was so well exposed by lord Bacon, in modern times; and which was practically illustrated in the triumph of Newton's empiric doctrines, over the hypotheses of Des Cartes.

No longer engaged in studying systems, and averse to speculation, even in regard to the symptoms of diseases, the empirics exerted their whole faculties in investigating the power of medicinal substances, which laid the foundation of their pre-eminence in pharmaceutical skill, and gradually effected those changes in the art of medicine which subsequently occurred. The properties of the productions of nature, especially of the vegetable world, were extensively examined; and the instruments of the physician, by which he could influence the functions of the living body, were greatly multiplied. It is chiefly to the industry of the ancient empirics that we are indebted for the introduction, or rather for the full knowledge, of sedative and narcotic remedies; on the liberal use of which probably depended the superior reputation acquired by some of them over their more cautious antagonists. Of this superiority, a singular instance occurs in the many existing testimonies to the fame of Heraclides of Tarentum, before mentioned, who is recorded as the most successful physician in any age or country of the world.

It is easy to see, however, that this direction of medical inquiry, given by the empiric physicians, to the discovery of the qualities of medicinal substances, or drugs, would in all probability lead to many abuses and evils. Experiment of this sort being much easier, at least when carelessly made, than that unremitting and accurate observation of the phenomena of diseases, which alone can constitute the scientific physician, the ignorant and idle would content themselves with pharmaceutical experiments, and neglect the task of pathological investigation; and selfish craft and dishonesty would soon learn to impose on the credulity of the people, in the administration of secret remedies, when the use of a particular drug, and not the general treatment of a disease, was supposed to be the essence of medicine. Hence it actually happened, even in the early ages of physic, that these ignorant and illiberal pretenders to panaceas, and infallible remedies, who did not know one disease from another by its symptoms, appeared in Egypt, Greece, and Arabia, and were much complained of by their more rational contemporaries. In all succeeding ages, the race of these illiterate pretenders has been multiplied, under the abused name of *empirics*. In our own time, indeed, while a college of physicians, constituted by royal and parliamentary authority, exists in the metropolis, for the regulation of the practice of medicine, and the prevention of the mischiefs occasioned by nostrum-mongers, and pretenders of all kinds, *quackery* thrives, unmolested by the college, and sanctioned, licensed, and protected by patent, on the part of government, to an extent heretofore unexampled. See *Cl. Hist. de la Med.* Schulzii *Hist. Med. Cels.* in *Præf. Galen.* *Loc. Cit.* Walker's *Mem. of Medicine*.

**EMPIRIC**, in *Modern Medicine*, is applied to a person, who sells or administers a particular drug, or compound, as

a remedy for a given disorder, without any consideration as to the variations of that disorder, in its different stages, or degrees of violence, or as it occurs in different constitutions, climates, or seasons, or in persons of different age, sex, strength, &c. Such a practice implies a total ignorance of the nature of the human constitution, both in health and disease; and therefore is generally found to be the resort of the illiterate and selfish, not to say dishonest, part of mankind. See the preceding article. See also *QUACK*.

**EMPIS**, in *Entomology*, a genus of dipterous insects. The mouth is furnished with an inflected sucker and proboscis; sucker with a single-valved sheath and three bristles; feelers short and filiform; antennæ setaceous. These are carnivorous, and subsist on flies and other small insects, which they seize with their feet, and pierce with their rostrum, to suck the blood and juices of their body. Some of the species are found on flowers, in the winged state: None of the larvæ are known.

#### Species.

**BOREALIS**. Black; wings subrotund and ferruginous-brown. Linn.

Inhabits Sweden, Britain, and various other parts of Europe, and is often seen in swarms in the air, like the gnat, on a still evening, about sun-set.

**PENNIPES**. Black, with the posterior legs long and feathered. Fabr. *Afilus pennipes*, Scop. Ent. Carn. 994.

Found in Europe, on the geranium sylvaticum and cardamine pratensis. A supposed variety is described by Linnæus, which has the four posterior thighs feathered, and the wings brown, with a black rib.

**MARGINATA**. Black; wings white, with black margin. Fabr.

A small species, found in Saxony.

**MAURA**. Black; shanks of the fore-legs thick and ovate. Fabr.

Inhabits environs of Hamburg, about stagnant waters.

**LIVIDA**. Livid; thorax pale-green, with three black lines; base of the wings and legs ferruginous. Fabr.

Frequent on the flowers of the cow-parsnip (*heracleum sphondylium*) in Europe. The wings are oblong, and veined with fuscous.

**CILIATA**. Blackish; wings with fuscous rib; legs black, four posterior ones feathered. Fabr.

Inhabits Europe, and in size resembles the last. The head is black, with a testaceous proboscis; thorax hairy.

**CINEREA**. Cinereous; thorax immaculate; legs pale; wings at the tip brownish. Fabr.

Inhabits Sweden, on umbellate flowers.

**MACULATA**. Cinereous; snout, sides of the abdomen, and legs testaceous; wings spotted. Fabr.

Native of Italy. The thorax is cinereous, with faint lines; legs testaceous, with black claws; abdomen with a testaceous line on each side.

**STERCOREA**. Testaceous, with a dorsal black line; wings reticulated. Linn. Fn. Succ.

On umbellate flowers, in Europe.

**MINUTA**. Black; legs testaceous; wings white. Fabr. Inhabits Denmark, on fungi. Small.

**CRASSIPES**. Black; all the shanks with a long thick joint; wings white, lower half of the outer margin black. Schranck.

Very small, and inhabits Austria.

**RUFIPES**. Black, and somewhat cinereous, legs ferruginous. Linn.

Native of Europe.

**QUADRILINEATA**. Black, and somewhat greyish; thorax

thorax with four lines; abdomen cylindrical, with the tip inflected. Linn.

Inhabits Europe.

**TRILINEATA.** Cinereous; thorax with three black impressed lines; wings white; legs pale-yellow. Linn.

Abdomen sometimes yellow, sometimes fuscous. This and the three following species inhabit Europe.

**NIGRICUS.** Cinereous; thighs black; shanks and wings ferruginous. Linn.

**GIBBOSA.** Fuscous; thorax gibbous; abdomen thin; wings spotted; shanks and ends of the legs white. Linn.

**FUSCIPES.** Brown-cinereous; wings white; legs livid; feet fuscous. Linn.

**LEUCOPTERA.** Thorax cinereous; abdomen black; wings white; legs livid. Linn.

**EMPLASTICS**, in *Pharmacy*, are salves, or medicines, which stop up and constrict the pores of the parts they are applied on; otherwise called *emphraclics*.

The word is formed from the Greek, *εμπλασσειν*, to stop up.

Such are fats, mucilages, wax, the whites of eggs, &c.

**EMPLASTRA AMYNTICA.** See **AMYNTICA**.

**EMPLASTRUM**, popularly called *plaster*, a medicine of a stiff, glutinous consistence, composed of divers simple ingredients, spread on leather, or linen, and applied externally.

The word is formed from the Greek, *εμπλαστῶν* or *εμπλασσω*, to put in a mass, or to smear over, because the em-plaster is made of divers kinds of simple drugs, worked up into a thick tenacious mass; or because it covers over the piece of leather or linen to be applied on the part affected.

Emplasters are made up in a strong solid body, that by remaining a long time on the part, the medicinal ingredients they are chiefly composed of, may have time enough to produce their effect.

The drugs used to give a body and consistence to em-plasters, are usually wax, pitch, gums, fats, litharge, and other preparations of lead.

There are emplasters of divers kinds, and used with divers intentions; stomachic emplasters; cephalic, styptic, hepatic, diaphoretic, resolutive, detergent, emollient, incarnative, astringent, conglutinative, &c. emplasters.

In the prescription of extemporaneous plasters, the greatest regard is to be had to that particular consistence which the part can most conveniently bear, whereupon the application is to be made. Thus, plasters to the breast and stomach, especially in the intention of emollients or discutients, should be yielding and soft, as in the officinal *emplastrum stomachicum*; but to the loins, or any of the limbs, where warm discutients and strengtheners are to be applied, an higher and more adhesive consistence is to be sought for. The emollient plasters likewise should be laid on thick, and frequently repeated, if the symptoms continue, because their better parts are soon spent. Discussants also applied to hard tumours, require repetition; but the strengtheners, which are purposely contrived of a strong adhesive consistence, are permitted to lie on till they grow dry, and come off spontaneously. In some stultent tumours, where a plaster alone will not prevail, they are at intervals taken off, and discutient fomentations or lotions made use of; such as are composed of bitters, carminatives, comprehending also lixivial salts or alkaline spirits.

**EMPLASTRUM Adhesivum**, *Adhesive Plaster*, now called "*Emplastrum lithargyri cum resinâ*," or "*litharge-plaster with resin*," is composed of three pounds of litharge or common plaster, with the proportion of half a pound of

yellow resin; and is prepared by melting the litharge plaster with a slow fire, and mixing the powered resin. The black sticking-plaster, called the lady's court-plaster, is formed by dissolving twelve ounces of the gum benjamin in twelve ounces of rectified spirit of wine, and straining the solution. In a separate vessel, dissolve a pound of the best isinglass in five pints of pure water; and after straining this solution, mix it with the former, and let them stand in a narrow vessel, that the grosser parts may subside: when the liquor is cold, it will become a jelly, which will melt near the fire when it is to be spread. This quantity will be sufficient for spreading on ten yards of half-yard wide silk; in order to which, the silk must be stretched in a frame, and the mixture may be spread upon it with a sponge or brush, which should be done near a fire. As each spreading dries, it must be repeated to the tenth or twelfth time, and then touched lightly with a brush to give it a gloss. The following more simple preparation may be substituted for the former; dissolve a pound and a quarter of fine isinglass in five pints of water, and before it cools spread it on silk in the manner above directed:

**EMPLASTRUM ex Ammoniaco cum Mercurio**, now called "*Emplastrum ammoniaci cum hydrargyro*," a form of medicine, ordered to be prepared in the following manner.

Take gum ammoniacum, strained, a pound; purified quicksilver, three ounces by weight; sulphurated oil, one dram by weight, or q. s. Rub the quicksilver with the sulphurated oil till the globules no longer appear; then add by degrees the gum ammoniac melted, and almost cooled again, and make the whole into a plaster.

This plaster is recommended in pains of the limbs, arising from a venereal cause. Indurations of the glands, and other violent tumours, are likewise found sometimes to yield to it.

**EMPLASTRUM Anodynum**, *Anodyne Plaster*, is prepared by melting an ounce of the adhesive plaster; and, whilst it is cooling, mixing with it a dram of powdered opium, and the same quantity of camphor previously rubbed up with a little oil. This plaster gives relief in acute pains, especially of the nervous kind.

**EMPLASTRUM Attrahens**, the *Dracoining Plaster*, now "*Emplastrum cereæ compositum*," a plaster ordered to be now made in this manner: take yellow wax and prepared mutton suet, of each three pounds; and yellow resin, one pound: melt all together, and strain the mixture while it is hot.

**EMPLASTRUM Cephalicum**, or "*Emplastrum picis Burgundicæ compositum*," is composed of Burgundy pitch, two pounds; ladanum, one pound; yellow resin and yellow wax, of each four ounces by weight; and expressed oil of nutmeg, one ounce by weight: to the pitch, resin, and wax, melted together, add first the ladanum, and then the oil of nutmeg.

**EMPLASTRUM Commune**, or "*Emplastrum lithargyri*," litharge plaster, a name given to what has been long called *diachylon-plaster*. It is ordered to be made of a gallon of oil of olives, and five pounds of litharge in very fine powder, boiled together on a slow fire, with about a quart of water, to keep them from burning, till they are perfectly mixed, and have the consistence of a plaster.

This plaster is generally applied to slight wounds and excoriations of the skin; it keeps the part soft and warm, and defends it from the air, which is all that is necessary in such cases.

**EMPLASTRUM Commune cum Mercurio**, or "*Emplastrum lithargyri cum hydrargyro*," is made in the same

manner as the ammoniacum-plaster with quicksilver, of litharge-plaster, one pound; purified quicksilver, three ounces by weight; and sulphurated oil, one dram by weight, or q. f.

**EMPLASTRUM *é* Cymino**, or "Emplastrum cumini," is composed of cummin, caraway, and bay-berries, of each three ounces by weight; Burgundy pitch, three pounds; and yellow wax, three ounces by weight. Let the pitch be melted with the wax; powder the rest, and mix all together.

**EMPLASTRUM Gummi**, *Gum Plaster*, now called "Emplastrum lithargyri compositum." Take of the common or litharge plaster, three pounds; strained galbanum, eight ounces by weight; common turpentine, ten drams by weight; and frankincense, three ounces by weight. Melt the galbanum with the turpentine, and mix with them, first, the powdered frankincense, and then the litharge plaster, previously melted with a slow fire. This is used as a digestive, and for discussing indolent tumours.

**EMPLASTRUM Roborans**, the *Strengthening-Plaster*, now called "Emplastrum thuris compositum," or compound frankincense plaster, is ordered to be made thus: take of the common or litharge-plaster, two pounds; of frankincense, half a pound; and dragon's blood, three ounces by weight: melt the plaster, and then add to it the other ingredients in powder.

**EMPLASTRUM Saponis**, *Soap-Plaster*, is made by mixing half a pound of soap with three pounds of melted litharge-plaster; and boiling them to the consistence of a plaster.

**EMPLASTRUM Stomachicum**, *Stomach-Plaster*, or "Emplastrum ladani compositum," is composed of ladanum, three ounces by weight; frankincense, one ounce by weight; cinnamon, powdered, expressed oil of nutmeg, of each half an ounce by weight; and oil of spearmint, one dram by weight. To the melted frankincense add, first, the ladanum softened by heat, and then the expressed oil of nutmeg. Mix these and the cinnamon with the oil of mint, and beat them together in a warm mortar. Let it be kept in a close vessel. An ounce or two of this plaster, spread on soft leather, and applied to the region of the stomach, will be of service in flatulencies, arising from hysteric and hypochondriac affections.

**EMPLASTRUM, Vescicatorium, Blistering-Plaster**, or "Emplastrum cantharidis," is formed by melting two pounds of plaster of wax, and half a pound of prepared hog's lard; and a little before they coagulate, sprinkling one pound of cantharides, finely powdered. In order to render blistering-plasters efficacious, care should be taken that the flies be good, fresh powdered, and the powder fine; and that the plaster should neither be made in too great quantity at once, nor spread with a spatula too much heated. See **BLISTER**.

**EMPLEURUM**, in *Botany*, from *επι*, in or upon, and *πλευρα*, the side, alluding to the lateral insertion of the stigma upon the germen. Soland. in Ait. Hort. Kew. v. 3. 513. Schreb. 812. Willd. Sp. Pl. v. 4. 333. Mart. Mill. Dict. v. 2. Juss. 298. Clafs and order, *Monocleia Tetrandria*. Nat. Ord. *Rutacee*, Juss.

Gen. Ch. Male. *Cal.* Perianth of one leaf, bell-shaped, four-cleft, permanent. *Cor.* none. *Stam.* Filaments four, thread-shaped, equal, simple, longer than the calyx, a little spreading; anthers erect, oblong, obtuse, somewhat quadrangular, of two cells, each bursting by a lateral siffure. Abortive germen sometimes present. Female on the same plant. *Cal.* as in the male. *Cor.* none. *Pist.* Germen inferior, oblong, compressed, of one cell, terminated by an erect leafy appendage; style none; stigma placed on a

lateral tooth at one edge of the germen, erect, cylindrical, smooth, deciduous. *Peric.* Capsule oblong, compressed; crowned with a leafy oblique appendage, of one cell, bursting at its straightest edge. *Seed* solitary, oblong, inserted laterally, enclosed in a bivalve, elastic, rigid arillus.—Very rarely two capsules are said to be found in one calyx.

Ess. Ch. Male, Calyx four-cleft. Corolla none. Sometimes with the rudiment of a germen. Female, Calyx four-cleft, inferior. Corolla none. Stigma cylindrical, standing on a lateral tooth of the germen. Capsule beaked, of two valves. Seed solitary, with an elastic arillus.

*E. ferrulatum*. Soland. in Ait. Hort. Kew. v. 3. 340. Sm. Exot. Bot. v. 2. 7. t. 63. (*Diosma unicapularis*; Linn. fil. in Suppl. 155. D. ensata; Thunb. Prod. 43.) This is the only species hitherto observed. Native of the Cape of Good Hope, where Thunberg, Masson, and others have gathered it. Masson sent it to Kew in 1774. It requires the shelter of a green-house, and the same treatment as other Cape plants of the Rutaceous order, *Diosma*, *Eriogonon*, &c. but is less ornamental than most of them, on account of the want of petals. The stem is shrubby, and much branched. Leaves ever-green, smooth, shining, alternate, almost sessile, linear-lanceolate, acute, bordered with shallow glandular ferratures, destitute of stipulas. Flowers on simple, axillary, clustered stalks, reddish, but inconspicuous. Capsules more striking, from their enlarged leafy termination. The whole plant, when bruised, smells strongly of rue or juniper, like most of its natural order. See **DIOSMA** and **ERIOSTEMON**.

**EMPNEUMATOSIS**, from *εμπνεω*, I inflate, in *Medicine*, a word used by some writers to signify an inflation of the stomach; but by others, in a more general sense, for inflations of the womb, or of any other part.

**EMPOLI, JACOPO DA**, in *Biography*, a painter of the Florentine school, who was born at Empoli, as his name designates, in 1554; and was first instructed in his art in the school of Maso di San Friano. He afterwards applied himself to study the works of Andrea del Sarto, and with very considerable success, acquiring very much his style of design, and hues and tones of colouring. He copied Del Sarto's works very closely, and not only his, but those of other masters, with so much accuracy, as to deceive the judgment of those well versed in the art. So much talent for this kind of exercise in art, is seldom accompanied by a power of invention or execution of original works. But Empoli had considerable reputation for this also, and his compositions are spoken of as possessing much spirit and ingenuity, and also exhibiting considerable feeling of beauty and elegance.

**EMPOLI**, in *Geography*, a town of Italy, in the duchy of Tuscany, situated on the Arno; 15 miles W. of Florence.

**EMPORETICA CHARTA**. See **CHARTA** and **PAPER**.

**EMPORIA**, in *Ancient Geography*, a country of Africa, on the Lesser Syrtis, in which Leptis stood. This territory was under the dominion of the Carthaginians, and was put under contribution by Masinissa. Leptis is said to have paid a talent *per* day to the Carthaginians. No part of the Carthaginian dominions was more fruitful than this. Polybius (l. i.) says, that the revenue which arose from hence was so considerable, that all their hopes were almost founded on it; and he deduces the origin of its name from its great fertility, and the commerce which distinguished it. To this were owing the anxiety and state-jealousy of the Carthaginians, lest the Romans should sail beyond the fair promontory, that lay before Carthage, and become acquainted with a

country which might induce them to attempt the conquest of it.

**EMPORIÆ, AMPOURIAS**, a town of Hither Spain, which lay towards the south, and which was, as its name imports, a commercial port. Strabo says, that the Massilians were established here: but Pliny and Silius Italicus say, that they were the Phocæans; both which reports may agree, as the inhabitants of Marseilles profess to have derived their origin from the Phocæans. According to Livy, this place consisted of two towns separated by a wall; that on the sea-coast, encompassed by a wall of 400 paces, was inhabited by Greeks, a colony of Massilians, who sprung from the Phocæans; and the other part, which had no communication with the sea, was surrounded by a wall of 3000 paces. This historian informs us, that Cæsar, after having defeated Pompey's party, established a body of Romans in this place. The Greeks, who were established in this place, had previously inhabited a small island opposite to it, from which they passed over to the continent. They worshipped Diana of Ephesus.

**EMPORICUS SINUS**, a gulf of Africa, in Mauritania. Ptolemy places it in the Adriatic sea, at  $34^{\circ} 20'$  of latitude.

**EMPORIUM**, a fortress of Italy, in Emilia, 5 miles from the Po.—Also, a place of Macedonia.—Another of Sicily.—Another of Italy, in Campania.—Another in Celtica. Steph. Byz.

**EMPORIUM**, in *Physiology*, is often used for the common sensory in the brain. See **BRAIN**.

**EMPRIMED**, among *Sportsmen*, a term applied to a hart, when he forsakes the herd.

**EMPRION**, from  $\epsilon\mu\pi\rho\iota\omega$ , to saw, in the *Medical Writings of the Ancients*, a word used to denote a peculiar pulse, in which the artery is felt to be distended in one part more than another at every stroke, and by that means is made to resemble any serrated body, or the light teeth of a fine saw.

**EMPROSTHOTONOS**, in *Medicine*, from  $\epsilon\mu\pi\rho\sigma\theta\omicron\tau\omicron\nu\omicron\varsigma$ , forwards, and  $\tau\epsilon\iota\nu\omega$ , I stretch, is the term applied to that form of tetanus, or general spasm, in which the muscles which bend the body forwards are most strongly affected, so that the whole body is rigidly fixed in a bent position, the neck and back being bowed forwards, the chin fixed upon the breast, &c. The term is used in opposition to **OPISTHOTONOS**, in which the body is bent backwards. (See **TETANUS**.) The emprosthotonos, however, is a very rare occurrence; and some writers have altogether denied its existence, except as a partial affection confined to the neck.

**EMPTOR FAMILIÆ**, *buyer of a family*, in the *Roman Law*, one who purchased the inheritance of a person, or the privilege of being appointed his heir by will.

This was done by the ceremony of scales and weights, before five witnesses, with the use of a peculiar formula of words.

Such buyer differed from the heir, *heres*, as the testator in some measure alienated the right to the former during his own life-time, whereas the latter had only a right by his death. Brisson. de Formul. lib. vii. p. 585. Pitisc. Lex. Ant. tom. i. p. 713. voc. *Emptor*.

**EMPTOR FIDUCIARIUS**, *fiduciary buyer*, one who receives a thing in the way of pledge, till the money he has advanced be repaid. Salmat. de Mod. Usur. cap. 14. Pitisc. Lex. Ant. tom. i. p. 713. voc. *Emptor*.

**EMPTYSIS**, in *Surgery*, bleeding from the mouth and fauces.

**EMPUS**, in *Geography*, a town of France, in the de-

partment of the Var, and district of Draguignan; 5 miles N.W. of Draguignan.

**EMPUSA**,  $\epsilon\mu\pi\upsilon\sigma\alpha$ , among the *Ancients*, a kind of hobgoblin, or bugbear, under the direction of Hecate, who used to send it to frighten people who laboured under misfortunes. Hofm. Lex. in voc.

**EMPYEMA**, in *Surgery*, signifies a collection of matter in the cavity of the thorax. The term is derived from  $\epsilon\mu$ , within, and  $\pi\upsilon\sigma$ , pus, or matter.

The ancients made use of the word "empyema" to express every kind of internal suppuration. Ætius first employed the term to denote the collections of purulent matter, which sometimes form in the cavity of the pleura, or membrane lining the chest; and all the best modern surgeons invariably attach this meaning alone to the expression.

The operation for empyema means the making of an opening into the thorax, for the purpose of giving vent to the matter collected in the cavity of the pleura. The necessity for having recourse to such an operation, however, does not often present itself. We would not wish to be thought to assert, that inflammation of the lungs, pleura, mediastinum, diaphragm, and even of the liver, does not sometimes terminate in suppuration. Certainly, the latter event is occasionally produced; but, when it does happen, the matter does not always make its way into the cavity of the chest. Very frequently external abscesses form, or the pus is either coughed up, or discharged with the stools.

When the surface of the lungs and pleura costalis have become adherent together, in the situation of the abscess, the pus, always disposed by a law of nature to make its way to the surface of the body, occasions ulceration of the intercostal muscles, and collects on the outside of them. An abscess of this kind comes on with a deep-seated pain in the part affected; an œdematous swelling, which retains the impression of the finger; and a fluctuation, which is at first not very distinct, but from day to day becomes more and more palpable, and, at length, leads the surgeon to make an opening to let out the matter.

If an opening be not made, when the fluctuation becomes perceptible, there is some risk of the matter insinuating itself into the chest, in consequence of the adhesion being in part destroyed by ulceration. M. Sabatier affirms, that the case may take this course, even when the abscess has been punctured, and while a free external opening exists. This experienced surgeon had occasion to remark such an occurrence in a soldier. The patient had a collection of matter in the thorax, which was only indicated by a pain all over the side; a difficulty of lying in any other position in bed, than on the back; and an undulating noise in the chest, whenever he altered his posture. When M. Sabatier made the patient hold his breath, the discharge, which was very copious, was not increased; the pus did not contain any bubbles of air; there was no emphysema round the wound; nor any blast of air from it in the motions of respiration. On opening the body, M. Sabatier found, that the abscess had been originally situated between the intercostal, and the pectoralis minor, and major, muscles, and that the matter had made its way, by several ulcerated openings, into the chest. The lung, in some places, was adherent to the pleura. The quantity of effused matter was very considerable. See *Medecine Opératoire*, tom. 2. p. 249.

In the same manner, if inflammation should occur in the anterior mediastinum and end in suppuration, the abscess may possibly burst into neither of the cavities of the chest; but make its way outward, after having rendered the sternum carious. The following case, illustrative of this fact,

fact, is taken from Van Swieten's Commentaries on Boerhaave's 895th Aphorism.

A young man was attacked with a violent pleurisy, which seemed to terminate in copious expectorations, which began about a fortnight after the commencement of the indisposition, and continued for a long while. The patient became exceedingly reduced, and his fate seemed inevitable. In the tenth month of his illness, however, a small soft swelling, about the size of a filbert, made its appearance upon the middle of the sternum, the substance of which bone appeared to be obviously carious round the margin of the tumour. The swelling burst of itself, and a discharge of matter ensued. Pus continued to be emitted from the opening for eight months. The cavity of the abscess was capable of containing a pint of the fluid, which was used as a detergent injection. The matter had collected between the pleura and the ribs. The patient recovered of this alarming disease, and was seen by Van Swieten in good health, eight months afterwards. There only remained a small fistulous opening, from which an inconsiderable quantity of matter continued to be discharged.

The foregoing case of abscess in the anterior mediastinum originated from an internal cause. It was the consequence of a violent pleurisy, or rather of a similar disorder, which is attended with nearly the same symptoms, but has a different situation, and has been very accurately described by Salus Diverius. The same sort of abscess may arise, in consequence of a wound in the forepart of the chest. An interesting case of this description is related by Galen. A young man, who had been wounded in the region of the sternum, seemed to have got completely well. An abscess then formed in the situation where the injury was received; it was opened, and healed. The part, however, soon inflamed and suppurated again. The place could not now be healed. A consultation was held, at which Galen attended. As the sternum was obviously carious, and the pulsation of the heart was visible, every one was afraid of undertaking the cure of the case, since it was conceived, that it would be necessary to open the thorax itself. Galen, however, engaged to manage the treatment without making any opening of the kind alluded to, and he expressed his opinion, that he should be able to effect a cure. Not finding the bone so extensively diseased, as was apprehended, and the mammary vessels being found, he began to indulge considerable hopes of success. After the removal of a portion of the bone, he saw the heart quite exposed, by reason of the pericardium having been destroyed by the previous disease. The patient, after the operation, experienced a speedy recovery.

M. J. L. Petit met with a case of an abscess in the mediastinum, in consequence of a gun-shot wound, in the situation of the sternum. The injury had been merely dressed with some digestive application; no dilatation, nor any particular examination of the wound had been made. The patient, after being to all appearances quite well, and joining his regiment again, was soon taken ill with irregular shiverings, and often febrile symptoms. M. Petit probed the wound, and found the bone affected. As there was a difficulty of breathing, he suspected an abscess either in the diploe, or behind the sternum, and, consequently, he proposed laying the bone bare, and applying a trepan. This operation gave vent to some sanious matter, and, as soon as the inner part of the sternum was perforated, a glass full of pus was discharged. The patient was relieved, and afterwards recovered.

When, in consequence of inflammation, an abscess forms deeply in the substance of the lungs, the pus more easily

makes its way into the air-cells, and tends towards the bronchia, than towards the surface of the lungs, and into the cavity of the thorax. In this case, the patient spits up purulent matter. When the opening, by which the abscess has burst, is large, and the pus escapes from it in a considerable quantity at a time, the patient is in some danger of being suffocated. However, if the opening be not immoderately large, and the pus, which is effused, be not too copious, a recovery may follow. Abscesses in the substance of the diaphragm, and collections of matter in the liver, may also be discharged by the pus being coughed up from the trachea, when the parts affected have become connected with the lungs, by adhesions, and the abscesses of the liver are situated on its concave surface. When the collection of matter in the liver occupies any other situation, the abscess frequently makes its way into the colon, and the pus is discharged with the stools. Several cases of this kind are related by authors: Sabatier has recorded two in his *Médecine Opératoire*; Le Dran mentions his having seen others; and Pemberton, in his book on the diseases of the abdominal viscera, p. 36, relates the occurrence of additional instances of a similar nature.

We shall now proceed to the consideration of empyema, strictly so called. No surgical writer, with whom we are acquainted, has written with more discrimination, than Mr. Samuel Sharp, on the symptoms produced by collections of matter in the cavity of the chest. He remarks, that it has been almost universally taught, that when a fluid is extravasated in the thorax, the patient can only lie on the diseased side, the weight of the incumbent fluid on the mediastinum becoming troublesome, if he places himself on the sound side. For the same reason, when there is fluid in both cavities of the thorax, the patient finds it most easy to lie on his back, or to lean forwards, in order that the fluid may neither press on the mediastinum, nor the diaphragm. But, Mr. Sharp takes notice, that however true this doctrine may prove in most instances, there are a few (Le Dran's *Obs.* 217. vol. i. Marchetti, 65.) in which, notwithstanding the extravasation, the patient does not complain of more inconvenience in one posture, than another, nor even of any great difficulty of breathing.

On this account, observes Mr. Sharp, it is sometimes less easy to determine, when the operation is requisite, than if we had so exact a criterion, as we are generally supposed to have. However, he informs us, that though this may be wanting, there are some other circumstances, which will generally guide us with a reasonable certainty. He states, that the most infallible symptom of a large quantity of fluid in one of the cavities of the thorax, is a preternatural expansion of that side of the chest, where it lies; for in proportion as the fluid accumulates, it will necessarily elevate the ribs on that side, and prevent them from contracting so much in expiration as the ribs on the other side. Mr. Sharp refers also to Le Dran's *Observ.* 211. vol. i. to prove, that the pressure of the fluid on the lungs may sometimes be so great, as to make them collapse, and almost totally obstruct their action. When therefore, says Mr. Sharp, the thorax becomes thus expanded after a previous pulmonary disorder, and the case is attended with the symptoms of a suppuration, it is probably owing to a collection of matter. The patient, he observes, will also labour under a continual low fever, and a particular anxiety from the load of fluid.

Mr. Sharp also observes, that, besides this dilatation of the cavity from an accumulation of the fluid, the patient will be sensible of an undulation; and sometimes the undulation is so evident, that a by-stander can plainly hear it in certain motions of the body. Mr. Sharp adds, that this

## EMPYEMA.

was the case with a patient of his own, on whom he performed the operation; but the fluid, in the example alluded to, he says, was very thin, being a serous matter, rather than pus.

According to the same author, it will also frequently happen, that though the skin and intercostal muscles are not inflamed, they will become œdematous in certain parts of the thorax; or if they are not œdematous, they will be a little thickened. These symptoms, joined with the enlargement of the thorax, and the preceding affection of the pleura or lungs, seem unquestionably to indicate the propriety of the operation. But, observes Mr. Sharp, amongst other motives to recommend it upon such an emergency, this is one, that if the operator should mistake the case, an incision of the intercostal muscles would neither be very painful, nor dangerous. See *Critical Enquiry into the present State of Surgery*; sect. on Empyema.

Although we would wish the reader to understand, that patients with empyema can sometimes lie in any position, without any particular aggravation of the difficulty of breathing, yet, we must distinctly state, that the generality of patients with this disease cannot place themselves on the side opposite to that where the collection of pus is situated, without having their respiration very materially obstructed. Another circumstance, also, which we wish to mention, now that we are treating of the symptoms of empyema, is, that the œdema of the integuments is sometimes not confined to the thorax, but extends to more remote parts, on the same side of the body as the collection of matter. Both the foregoing remarks are confirmed by an interesting case, which Mr. Hey, of Leeds, has lately published.

Sept. 3, 1788, Mr. Hey was desired to visit John Wilkin-son, who had been ill, ten days of the influenza. The patient was found labouring under a fever, attended with cough, difficulty of breathing, and pain in the left side of the thorax. He was bled once; had repeated blisters applied to the thorax; took nitre and antimonials, with a smooth linctus to allay his cough. He was repeatedly relieved by these means, especially by the application of the blisters; but repeatedly relapsed. At last, he became so ill, that he breathed with the utmost difficulty, and "could not lie on the right side without danger of immediate suffocation."

Mr. Hey found the patient in the state just now described on the 17th of September. "His face, and especially the eye-lid, were a little swollen on the left side." The left side of the thorax was larger than the right, and its integuments were œdematous. Upon pressing the intercostal muscles they felt distended; they yielded a little to a strong pressure, and rebounded again. The abdomen, especially at its upper part, appeared to be fuller than in its natural state. See *Practical Observations in Surgery*, p. 476.

Another remarkable symptom, which is occasionally produced by collections of matter in the chest, is an alteration in the position of the heart. Mr. Samuel Cooper has made mention of a patient who was in St. Bartholomew's hospital, whose heart was pushed quite to the right side of the chest, by an empyema in the left bag of the pleura, and pulsated on the right of the sternum. *First Lines of the Practice of Surgery*; part 2. chap. 29.

The symptoms of empyema are frequently very equivocal, and the existence of the disease is generally somewhat doubtful. Panarolius opened a man, whose left lung was destroyed, at the same time that the thorax contained a considerable quantity of pus. Although the patient had been ill for two months, he had suffered no difficulty of breathing, and had had only a slight cough. *Le Dru met*

with a case of nearly the same kind. A patient who had been for three days affected with a considerable oppression, and an acute pain on the left side of the chest, got somewhat better. He felt no material difficulty of breathing, on whatever side he lay. The only thing which he complained of, was a sense of a fluctuation in his thorax, and a little obstruction to his respiration, when he was in a sitting posture. These symptoms did not seem sufficiently decided to justify the operation, and it was delayed. The febrile symptoms continued with cold sweats, and the patient died on the eighth day. Five pints of pus were found collected in the chest.

With respect to opening such abscesses as present themselves at some part of the parietes of the thorax, in consequence of a pleurisy, or an inflammation of the diaphragm, or mediastinum, it is not attended with any peculiarity. It should be done as soon as a fluctuation can be felt, and the aperture should be made of sufficient size to give free vent to the matter. As some of these abscesses communicate with the external surface of the lungs, and others with that of the liver; as some of them are accompanied with a caries of the ribs, or the cartilages of these bones, while others are attended with an alteration of the substance of the sternum; the cure must frequently be interrupted by unpleasant symptoms, and very often retarded for a long while, especially when there are some pieces of bone to exfoliate.

We shall next consider the operation for empyema, in the common signification of this term.

Mr. Samuel Sharp advises the incision to be made between the sixth and seventh ribs, half way from the sternum towards the spine; which, says he, though not the most depending part of the thorax, when we are erect, yet is situated sufficiently low to give issue to the fluid, when we lie down.

This author was certainly mistaken in his opinion, that the expansion of the lungs always propelled the pus out of the wound, but the action of such muscles, as diminish the capacity of the thorax, may undoubtedly produce this effect. The reader, on looking over the article ΕΜΠΥΣΕΜΑ, will be perfectly convinced, that the lungs cannot become distended with air, and expanded on one side, while, on this side of the chest, there exists a free communication between the outward air and the cavity of the pleura.

Mr. Sharp quotes the practice of Marchetti, who always made the opening between the fifth and sixth ribs, to confirm the prudence of choosing this situation for the incision. See *Critical Enquiry*, &c.

A great many of the most eminent writers on the operations of surgery have had hardly any other object in view, in the operation for empyema, than making an opening into the thorax in such a situation, as would be a most depending one, in the erect position of the body. Hence these authors even sanction and recommend the unnecessary plan of cutting through the muscles of the back to make an issue for the matter in the exact place, which, according to their principle, ought to be chosen. We are sorry, that the respectable names of Bertrandi and Sabatier might be adduced in favour of this mode of proceeding.

The safest, and most convenient situation, for making an opening into the chest, is between the sixth and seventh true ribs, on either side, as circumstances may render necessary. The surgeon should only recollect, that the two cavities of the pleura are completely distinct from each other, and have no communication whatsoever, so that, if fluid were contained on the left side of the thorax, making an opening into the right cavity would not serve for discharging the accumulated matter. The practitioner should also remember,

remember, that, when there is a fluid on both sides of the chest, paracentesis must never be done for the relief of the two collections at the same time; because, there is great reason to believe, that, as the lungs on one side usually collapse, when there is a free communication between the air and inside of the thorax, they would do so on both sides, were an opening made at the same time into each bag of the pleura. It is hardly necessary to remark, that, in this condition, the patient could not breathe and would die suffocated. The operation consists, in making an incision, about two inches long, through the integuments, which cover the space between the sixth and seventh true ribs, just where the indigitations of the serratus major anticus muscle meet those of the externus obliquus. Here it is unnecessary to divide any muscular fibres, except those of the intercostal muscles, and, by putting the patient in a proper posture, the opening that is made, will be depending enough for any purpose whatsoever. The surgeon, avoiding the lower edge of the upper rib, where the intercostal artery lies, is then cautiously to divide the intercostal muscles, till he brings the pleura into view, when this membrane is to be very carefully divided with a lancet. The instrument should never be introduced in the least deeply, lest the lungs should be injured. The size of the opening in the pleura should never be larger than necessary. The discharge of blood and matter will of course require a freer aperture, than that of air, or water. If requisite, a cannula may be introduced into the wound, for the purpose of facilitating the evacuation of the fluid, and it may, even in some cases, be proper to let this instrument remain in the part, in order to let the water, or pus escape, as often as another accumulation takes place. It is obvious, however, that a cannula, for this object, should only be just long enough to enter the cavity of the pleura, and should have a broad rim to keep it from slipping into the chest. A piece of sticking plaster would easily fix the cannula, which might be stopped up with a cork, or any other convenient thing, or left open according as the circumstances of the case, and the judgment of the surgeon, may direct.

It is proper to state, that some practitioners make the wound between the fifth and sixth ribs: thus, Mr. Hey, in relating an interesting case of empyema, informs us, that the pain which the patient had felt in his side had been most acute betwixt the fifth and sixth ribs, and that there he (Mr. H.) made an opening into the cavity of the thorax. His first incision was about two inches in length. He cut through the serratus and intercostal muscles close to the upper edge of the sixth rib, and made an opening into the chest capable of admitting the tip of his finger. A large quantity of matter was thus discharged, and a leaden cannula was introduced into the wound on the second day after the operation, and was retained in its place by a flannel bandage. Mr. Hey did not allow the patient to leave off wearing the cannula, until the discharge from the thorax had ceased, and he had completely regained his strength. He wore it fifteen months.

Mr. Hey thinks it of great consequence to retain a cannula in the wound, until all probability of relapse is removed. This precaution, he apprehends, will not hinder the patient from recovering his strength, even when the use of the instrument is not absolutely necessary. See Hey's Practical observations in Surgery, p. 477, &c.

EMPYEMATA, suppurating medicines.

EMPYI, patients with empyema.

EMPYREUM, among *Divines*, denotes the highest of the heavens, where the blessed enjoy the beatific vision; called also empyrean heaven, and paradise.

The word is formed of *εἰ* and *πῦρ*, *fire*, because of its splendour.

EMPYREUMA, in *Chemistry*, is that smell and taste of scorching which takes place in most animal and vegetable substances, when heated to that point at which decomposition by fire begins. It is always attended with a darkening of colour of substances naturally clear and limpid. The degree of heat at which this change occurs is various, but it is always above that of boiling water, so that the use of a boiling water-bath for digestions, or desiccations, is an effectual mode of preventing empyreuma. There is, however, a change that takes place in vegetable decoctions or infusions when evaporated to the consistence of an extract, however low the heat is kept, since when these extracts are again diluted to their original consistence, they differ both in sensible and chemical properties, from the original liquor. The causes of this change are, probably, in part the action of the external air, but principally, several complicated chemical actions that take place between the various component parts of the vegetable substance itself, when their particles are concentrated by evaporation of the water which held them in solution. This circumstance is often confounded with empyreuma, properly speaking, or the changes produced by heat pushed to the degree at which decomposition occurs, and as some of the effects appear to be nearly similar, it is perhaps impossible to adhere strictly to the real distinction. The leading circumstance that indicates empyreuma in vegetable and animal matters is the *charring*, or conversion into black carbon, of part of the substance thus heated, whence a carbonaceous insoluble powder is produced, which partly subsides on dilution with water, and partly remains finely suspended.

The smell and taste of empyreuma in vegetable infusions, may be in many cases got rid of by filtering through recently-burned charcoal powder.

EMPYREUMA is also used for the heat remaining upon the declension of a fever.

EMPYREUMATIC ACID and OIL, in *Chemistry*. When most animal and vegetable substances are distilled *per se* in a heat gradually urged to redness, a dark-coloured strong smelling oil almost invariably rises towards the end of the process, which is strongly empyreumatic.

Many vegetable substances yield also, at the same time, a strongly acid and empyreumatic liquor, which appears to be chiefly acetous acid generated in the process, and holding much carbonaceous matter in solution, from which it may be partly freed by a separate distillation in a gentle heat. See PYROLIGNEOUS and PYROMUCOUS ACID.

EMRODS, or rather HÆMORRHOIDS. See HÆMORRHOIDS.

EMS, in Latin *Amisia*, or *Amasus*, in *Geography*, is a considerable river of Germany, which has its source in the county of La Lippe, in Westphalia, flows through East Friesland, and falls into the North sea, near Emden. It gives its name to one of the new departments of Holland, which is the ancient province of East Friesland, whose chief place is the town of Leuwarden.

Ems, a town of Germany, in the circle of the Upper Rhine, and principality of Hesse-Darmstadt; seven miles E.S.E. of Coblenz.

EMSBACH, a river of Germany, in the circle of the Lower Rhine, which runs into the Lahn, three miles E. of Limburg, in the electorate of Treves.

EMULATION, is a generous ardour kindled by the brave examples of others, which impels us to imitate, to rival, and, if possible, to excel them. This passion involves in it esteem of the person whose attainments or conduct

we emulate, of the qualities and actions in which we emulate him, and a desire of resemblance, together with a joy springing from the hope of success.

The word comes originally from the Greek *αμιλλα*, *dispute, contest*; whence the Latin *emulus*, and thence our emulation.

Dr. Hartley refers emulation to a class of the sympathetic affections, by which we grieve for the happiness of others; and Dr. Reid, in his "Essays," (p. 167,) defines it as a desire of superiority to our rivals in any pursuit, accompanied with an uneasiness at being surpassed. He classes it, together with resentment, under the head of the malevolent affections, which, though they are parts of our constitution, given us by our Maker for good only, and, when properly directed and regulated, of excellent use, are nevertheless subject to excess or abuse, and thus become the source and spring of all the malevolence that is to be found among men. From the observations which he has introduced for the illustration of this affection, he infers, that emulation, as far as it is a part of our constitution, is highly useful and important in society; that in the wise and good, it produces the best effects without any harm; but in the foolish and vicious, it is the parent of a great part of the evils of life, and of the most malignant vices that stain human nature.

Plato observes of emulation, that it is the daughter of envy; if so, there is a great difference between the mother and the offspring; the one is a virtue, and the other a vice. Emulation admires great actions, and strives to imitate them; envy refuses them the praises that are their due; emulation is generous, and only thinks of surpassing a rival; envy is low, and only seeks to lessen him.

Perhaps, therefore, it would be more just to suppose emulation the daughter of admiration: admiration, however, is a principal ingredient in the composition of it.

EMULGENT, in *Anatomy*, a term applied to the blood-vessels of the kidneys. See *ARTERIES* and *VEINS*.

EMULSION, from *emulgere*, to milk, in *Chemistry* and *Pharmacy*, is any milky opaque liquor formed by the diffusion of any oily or resinous matter in water, through the medium either of alkalies, or of mucilage, or any other viscid matter soluble in water.

Milk itself is a natural emulsion, and when viewed in a powerful microscope is seen visibly to consist of oily particles suspended in a serous liquor. Many vegetable matters form natural emulsions when merely triturated with water, of which kind are almonds, and most of the oily nuts, the oil being held suspended by the mucilage or farina with which these substances naturally abound.

All the oils are rendered miscible with water, when rubbed with mucilage of gum arabic, or with the yolk of egg, or with a small quantity of any alkaline salt, and all these mixtures are common in pharmacy. Thick syrups also promote the diffusion of oily matters in water, but less perfectly.

This combination, however, is but temporary, as all the emulsions are decomposed by mere rest for some hours, and as besides they are very apt to ferment, they are only used in extemporaneous prescription.

The common emulsion, now called "Lac Amygdalæ," is made by beating an ounce and a half by weight of sweet almonds, with half an ounce by weight of double refined sugar, in a marble mortar, and rubbing them well together; adding gradually the quantity of two pints of distilled water, and straining the liquid. If two ounces and a half of the mucilage of gum arabic are added to the almonds whilst they are pounded in the mortar, we shall have the

arabic emulsion. These emulsions may be used as ordinary drink, in cases which require soft cooling liquors. The camphorated emulsion is prepared by grinding half a dram of camphor, and half a dozen sweet almonds together in a stone mortar, and adding by degrees eight ounces of mint water, straining the liquor, and dissolving in it half an ounce of white sugar. A table spoonful of this emulsion may be taken in fevers, and other disorders which require the use of camphor, every two or three hours.

The emulsion of gum ammoniac is made by grinding two drams of the gum with eight ounces of water poured gradually upon it till it is dissolved.

This emulsion is used for attenuating viscid phlegms, and promoting expectorations. In obstinate coughs, two ounces of the syrup of poppies may be added to it. It may be administered in a dose of two table spoonfuls, three or four times a day. The oily emulsion, prepared by mixing six ounces of soft water with two drams of volatile aromatic spirit, and an ounce of Florence oil, and half an ounce of simple syrup, is serviceable in recent coughs: in more obstinate coughs, it will be better to substitute for the aromatic spirit the paregoric elixir of the Edinburgh Dispensatory. A table-spoonful of it may be taken every two or three hours.

EMUNCTORY, in *Anatomy*, from *emungo*, to clean or wipe the nose, is any part of the body, which separates from the blood humours judged to be impure or excrementitious, and therefore hurtful. This process is supposed to purify the blood. The kidneys and skin are called the common emunctories, as they afford very copious secretions. This notion of the separation of noxious particles is built on the opinions of the older physiologists; and consequently the use of the term emunctory has at present nearly ceased.

EMUNGS, in *Geography*, one of the Pelew islands.

ENABY, a town of Sweden, in the province of East Gothland; 20 miles S. of Linköping.

ENADA, in *Ancient Geography*, a town of Palestine, in the tribe of Issachar, according to the book of Joshua.

ENÆMON, *Εναιμων*, from *αιμα*, blood, an external medicine which stops or itanches the blood; or which, by binding, cooling, or drying, closes the passages of the vessels before open, or diminishes the fluidity and motion of the blood. See *STYPTIC*.

ENÆOREMA, *Εναιωρημα*, from *αιωνω*, to exalt, expresses such contents of the urine as float about in the middle, resembling a cloud; and thence also called nubecula. See *URINE*.

ENAGARA, in *Ancient Geography*, an island of Asia Minor, in the Mediterranean sea, placed by Pliny over against Lycia, and near the isle of Crete.

ENAIM, a town of Judea, in the tribe of Judah, according to the book of Joshua.

ENALLAGE, in *Rhetoric*, a figure whereby we change and invert the order of the terms in a discourse, against the common rules of language.

The word is derived from the Greek, *εναλλαγη*, formed of *εναλλαττειν*, which signifies *to change*, as well as the simple verb *αλλαττειν*.

The grammarians too have a kind of enallage, whereby one part of speech, or one accident of a word, is put for another.

Such is the change of a pronoun, as when a possessive is put for a relative, *e. gr.* *suus* for *ejus*; or of a verb, as when one mood or tense is put for another.

ENALURON, in *Heraldry*, is used by Guillim to express a bordure charged with birds; as an enaluron of martlets,

martlets, &c. but Mackenzie charges this as a mistake arising from ignorance of the French tongue; enaluron properly signifying orle, or in manner of a bordure, and being applicable to a bearing of any thing in that form.

ENAMBUSH, in *Military Affairs*, relates to a device used for the purpose of surprizing an enemy, either on his route, or when pursuing a small body of troops sent out for the purpose of decoying him into the snare. This insidious practice is often of considerable service in the minor branches of warfare, but can rarely be practised on a great scale; though history furnishes us with instances of armies having been taken by surprize, owing to the cunning of their adversaries, in lying concealed in such places as enabled them to take advantage of an unsuspecting commander. This, however, is not what in strictness is termed an *ambush*. That term more properly is confined to that kind of preconcertion, which rather leads an enemy into the danger, by some supposed advantage held out to his acceptance, whether it be for forage, the seizing of a depot, the interception of a convoy, or the attack upon some weak post. Here we see an immense field open for contrivance and speculation. It is to be understood, that when a body of troops is placed in ambush, certain intelligence has been obtained of the numbers, route, and object of those who are to be intercepted. If these be not previously ascertained, the ambuscade may prove fatal: since, should it turn out that, instead of five hundred, five thousand were to be attacked; that, in lieu of their being foragers laden with booty, they should prove to be a body of light horse, with riflemen at their backs; or that, instead of being a detachment sent to surprize some small outpost, they should be the advanced guard of a strong column:—in either of these cases, a sad reverse would take place; for, although at the first brush, there might be some surprize, and possibly some confusion, it would in all probability be but for the moment; after which the assailed party would press forward with great eagerness, and by means of their flanking parties cover the speculators with disgrace and ruin. The most deadly kind of ambuscade is that wherein fire-arms are rejected, the whole depending upon pikes and cutlasses: in such, silence is an important object, even in the very moment of falling upon the enemy. This not only prevents the other parts of the line from being able to ascertain the exact situation of the assailants, as may always be done by observing the flashes from musketry, &c.; but renders it impossible to ascertain their numbers. Add to this, that when men fire, in the dark especially, at a moving object, they are by no means certain of their aim; nor can they so speedily recover themselves, after their pieces may have been discharged. Besides, it is well known that pikes cause infinite consternation, when coming to close quarters; being much longer than the musket with the bayonet attached, they are infinitely more destructive, when properly used in this species of warfare. In many countries, it is next to impossible to enambush the enemy; while, in others, almost every spot affords the means of concealment. The great art is, to avoid all common-place modes of laying *perdue*: such are rarely successful, owing to that invariable attention paid towards the examination of every such suspicious situation. On the other hand, those parts which are least suspected often prove particularly formidable; but where such are resorted to, the means of retreat, or at least of defence, ought to be fully established. Those ambuscades which are the most collected, always carry the greatest probability of success: they are least liable to detection, far more pointed in their attack, and most calculated for resistance, when prematurely discovered.

Cavalry is rarely employed in ambushes, though a considerable body may, if convenient, be posted in a proper direction, for the purpose of supporting the infantry concealed in woods, &c. On some occasions, it is even advantageous that such cavalry should be visible, but in an opposite quarter; so as to cause the force to be attacked to be concentrated, by calling in their scouts and videttes; by which those in ambush might else be discovered. This device likewise occasions the baggage to be sent upon the other flank, out of the way of the cavalry, and leaving that flank towards them free from incumbrance. When this happens, and that the cavalry make a shew of charging, the baggage will commonly fall into the hands of those in ambuscade. Naval ambuscades are by no means uncommon: it often happening that a well-concerted decoy lures an enemy into such a situation as at least places him under considerable disadvantage, or eventually causes him to surrender. Thus, disguising vessels by means of new painting; changing their mode of rigging; appearing to avoid rather than pursue; sending out a slow sailing vessel to pass between a cruiser and an island, behind which a superior force is concealed, &c. &c. are all *ruses de guerre* in common use. One device, which probably would otherwise be often practised, is contrary to the laws of honour and the rules of war, namely, making signals of distress, with the view to draw an enemy's vessel to give assistance, and then to capture her. To assume the appearance of being damaged, either by weather or by action, is all fair; because then the enemy bears down as upon a prey, and not as a protector. However, the practice of enambushing, whatever advantages it may seem to offer, is subject to extreme danger: unless guided by the most certain knowledge of the force to be surprized, it becomes almost invariably a losing concern, and has the pernicious tendency of creating great diffidence in the conduct of that commander by whose instructions it is made. Nor can the smallest success be hoped for, unless where the peasantry are friendly disposed, and the country around thoroughly known.

ENAMEL, in *Anatomy*, the hard substance which covers the crown of the tooth. It is described in the account of the teeth, contained in the article CRANIUM.

ENAMEL, in the *Arts*. Enamels are vitrifiable substances, and may be arranged into three classes, *viz.* transparent, semi-transparent, and opaque. The two former are chiefly employed in enamelling on gold and silver, for watch-cases, trinkets, and other small articles of jewellery; the latter is principally used on copper, for the making of clock and watch-dial plates, and for other plates which, when properly fluxed, are fit for the purpose of enamel-painting.

The basis of all kinds of enamel is a perfectly transparent and fusible glass, which is rendered either semi-transparent or opaque, by the admixture of metallic oxyds. White enamels are composed by melting oxyd of tin with the glass, and adding a small quantity of manganese, to increase the brilliancy of the colour. The addition of oxyd of lead, or antimony, produces a yellow enamel; and Kunckel affirms that a beautiful yellow may be obtained from silver. Reds are formed by an intermixture of the oxyds of gold and iron; that composed by the former being the most beautiful and permanent. Greens, violets, and blues, are procured from the oxyds of copper, cobalt, and iron; and these, when intermixed in different proportions, afford a great variety of intermediate colours. Sometimes the oxyds are mixed before they are united to the vitreous bases. Such are the principal ingredients employed in the production of the various enamels; but the proportions in which they are used, as well as the degree and continuance of the heat

heat necessary to their perfection, constitute the secrets of the art. Other substances than those here mentioned are occasionally used in the composition of enamels; and it has been said, that the peculiar quality of the best kinds of hard or Venetian enamel is owing to the admixture of a particular substance found on mount Vesuvius, and known to be thrown up by that volcano.

The work of Neri on glass, with the notes of Merret and Kunckel, afford many good precepts for making enamels; yet the exact nature and methods of composition of the best kinds, both of the hard and soft enamels, still remain among the arcana of enamelling. The soft white enamel is generally called glass, and is manufactured at the glass-house, near the site of the Albion mills, on the Surrey side of Blackfriars-bridge; the hard enamels are chiefly made at Venice, and, from the operations of the war, are not at present to be procured in London. In consequence of this, the best enamel, which formerly, when smuggled into the kingdom, has been sold as low as from 2s. to 2s. 6d. per lb., and even when the duty has been paid at the Custom-house, at from 3s. to 4s., has progressively advanced to a guinea, and from that to 5s.; and it cannot now be obtained at any price.

ENAMEL-Painting. See PAINTING on Enamel.

ENAMELLING. The art of enamelling is of great antiquity, but of unknown origin. That it was practised by the Egyptians is evident, from the remains that have been observed on the ornamental envelopes of mummies. From them it probably passed to the Greeks, and afterwards to the Romans, who appear to have introduced the art into this country; as various Roman antiquities have been dug up in different parts of Britain, in which enamels have formed portions of the ornaments. That the Britons received the art from their conquerors may be conjectured from the circumstance of enamelled trinkets having been found in British barrows. That the Saxons practised it is certain, from the jewel found at Athelney in Somersetshire, and now preserved at Oxford; which jewel, as appears by the inscription, was made by command of the great Alfred. The gold cup, given by king John to the corporation of Lynn in Norfolk, proves that the art was not lost under the Normans; for the sides of that cup are embellished with various figures, whose garments are partly composed of coloured enamels. The tomb of Edward the Confessor in Westminster Abbey, constructed in the reign of Henry III., was also ornamented with enamels, pieces of which still remain. The beautiful crozier of the celebrated William of Wykeham, of the time of Edward III., may be also adduced as exhibiting some curious specimens of the application of this art: and other examples might be pointed out, of its progressive descent to our own age.

It would seem from the above brief review, that anciently enamels were principally applied to the purposes of ornament; but since the invention of clocks and watches, their usefulness has been proportionally increased. For clock and watch dials there is probably no substance that could be substituted, that can equal enamel in permanence and beauty: in several respects, it possesses advantages even over the rich metals of silver and gold. Within the last 30 or 40 years, an *imitative enamel* has been used, and, through the scarcity of real enamel, is now in much demand for clock plates; but it is by no means comparable with its prototype: for, being chiefly composed of flake white, ground up with spirits of turpentine, and afterwards mixed with copal varnish, it will neither assume an equal brilliancy in colour, nor continue unchanged in different climates; on the contrary, the action of the air occasions it

to become dingy and yellow. In fact, imitative enamelling is nothing more than a branch of the art of *japanning*; which see.

The processes of enamelling have never been accurately described. The jealousies that exist in all arts in which any thing like a scientific knowledge is wanting, operate to seclusion. The practitioner conceals his information from motives of profit, and the amateur seldom acquires an insight sufficiently minute to enable him to unfold the modes of operation. Whatever may be the defects of the present attempt, it will be found to contain a better account of the practical branches of the art than has before appeared.

Enamels are commonly laid upon a metal ground, yet they have been sometimes used in substance, for dishes, flower-pots, ornamental vessels, figures, vases, &c. In these cases, the enamel is run into moulds immediately from the pots in which it has been melted. The metals employed to enamel on are gold, silver, and copper. Of the other metals, some are too fusible to endure the action of the fire, and the remainder, as platina, &c. are, to use the language of the art, too *strong*, for the enamel: that is, the adhesion between the two substances is not powerful enough to keep them together, the enamel cracking as it grows cold, and flying off the metal in flakes. It appears, therefore, that a certain, however slight, degree of oxydation is necessary to make the enamel and the metal unite with sufficient firmness. Gold is unquestionably the best substance to enamel on, its richness of colour showing a beautiful tinge through the enamel: yet the metal generally used, except for watch-cases, and valuable articles of jewellery, is copper; and that on account of its superior cheapness. Both the gold and the copper should be of the finer kinds, the others being too refractory to agree properly with the enamel.

By the custom of the trade, rather than from any principle of utility, enamelling is now divided into two branches, *viz.* dial-plate enamelling, and transparent enamelling. The former includes the manufacture of clock and watch plates, with fluxed plates for enamel painting, the latter comprehends the enamelling of watch cases, broaches, pins, and other bijoux: of late years the making of these lesser articles has gradually grown into great disuse in this country.

*Dial-Plate Enamelling*, consists of the two divisions of hard-enamelling, and soft, or glass enamelling; in the first branch, the Venetian enamels only are employed, in the last, the English or glass enamels. The practice of hard-enamelling requires more skill, time, and labour than the others, and is consequently esteemed the most. In preparing the metals to be enamelled on, whether of gold, silver, or copper, the process is similar; one description will therefore suffice for the whole:—and first of the making of watch dials.

The copper being evenly flatted in long slips (which is done at the flating mills between steel rollers) and to a proper thickness, pieces are cut off for use according to the size wanted. They are then annealed in a clear fire, in order to make them sufficiently pliable to take the required forms which is given to them by means of dies. The dies are small circular plates of brass evenly turned, varying in thickness, perhaps, from the sixteenth of an inch to an eighth, or more, according to their diameter. Some of them are flat, others are hollowed out for the purpose of giving a slight curve to the *copper*, as the metal to be enamelled on is technically termed when prepared for use: the edges of the dies are turned off in an oblique direction, and in the centre is a small hole, rather larger than that which is wanted in the dial-plate. A complete set of dies varies in size from about three-fourths of an inch to two inches and a half, the gradations being very small, perhaps

## ENAMELLING.

not more than the thirty-second part of an inch between each.

The copper being cut with a pair of scissars nearly to the size required and properly annealed, is next placed on the die best adapted for the purpose, and the eye, or centre hole, is made. This is effected by first forcing up the copper into the hole of the die with a small round-headed punch; by this means a small concave bulge is formed, the upper side of which is then filed through with a smooth grained file; it is then again placed on the die, and pressed gradually open till it nearly fills the hole with an oval burnisher; it is afterwards pressed tighter into the hole with a round broach, the burr being occasionally taken off by the file, and care employed to prevent the eye from cracking. The punch, burnisher, and round pin, are all of steel; the two latter taper in regular gradation towards the handles.

When the eye is completed, the edge of the copper is cut round, so as to leave a small part, probably about the thirtieth of an inch, projecting beyond the die. The projecting part is then turned up, or burnished, against the edge of the die, the copper being first laid smooth and flat by the burnisher. The turned-up edge of the copper is afterwards filed evenly round, and reduced to the proper height, according to the thickness of the brass-edge, or rim, to which it is to be fixed when in the watch. The inside burr is then scraped off with a graver, and still further cleared away by means of a scratch-brush: this latter tool is composed of small brags or steel wire tied together in a round bundle, about the size of the little finger. The purpose for which the eye of the copper is formed, and the edge turned up, is to retain the enamel in its proper place, so that the plate may be finished both square and neat.

According to the kind of watch to which the dial is to be applied, the copper, if for a seconds watch, must be kept almost flat; or if for a watch where a greater space is wanting beneath, to give more scope for the wheels, must be raised from the edge to the centre in a regular and exact manner. To effect this a small circular block or setting die is used, made of box or other hard wood turned out to the necessary degree of concavity, and having a hole in the middle to receive the eye of the copper when placed within the hollow of the block. The copper is then gradually set up to the convexity or height required by rubbing it gently yet firmly with a bent, or setting spatula, formed of a thin slip of steel, about five inches long, properly fixed. It is now ready to have the feet foldered on, by which it is to be pinned down to the brass edge or frame of the watch; and the places for the feet being marked on the back of the copper, through the holes drilled for the purpose in the edge or frame, the feet are prepared for foldering.

The feet are always of wire of the same kind of metal as that to be enamelled on, and the wire is drawn into different thicknesses, proportioned to the size of the intended dial-plate; thus varying perhaps from the tenth to the sixteenth of an inch. In the more common kinds of enamelling, the feet are generally cut off from silvered wire, that is, copper wire plated with silver; the silver itself forming the folder when the feet and copper are exposed to the united action of the lamp and blow-pipe. In the best kind of work plain copper wire is used, and the feet are fastened to the copper by means of speltre, or of silver folder. When sufficient care is exercised, either of these modes is equally appropriate, but the feet foldered on with speltre take the firmest hold; those with the silvered wire the slightest. The feet are evenly filed, either to a flat face, or an angular one, according to the description of copper for which they are

wanted; and are cut off the wire into proper lengths by a pair of cutting-pliers or nippers. In order to make the feet remain in their places, and facilitate the foldering, the end of each foot, before putting it on the copper (which is done by means of a pair of corn-tongs or tweezers), is dipped into a slight wash of borax and water, through which it adheres with sufficient force to admit of its being exposed to the power of the blow-pipe. The lamp in common use contains from a pint to a quart of oil, and has a cylindrical spout projecting about three inches, and being an inch or more in diameter. This space is filled with cotton, which being lighted, a good strong flame is produced. The copper is carefully placed upon a piece of solid charcoal, long enough to be held in the hand, and the flame being then propelled by the blow-pipe against the folder, or silvered wire, as the case may be, the feet are firmly united to the copper. In this operation, attention must be given to the exact degree of heat required to fuse the folder, for should it be too powerful, the copper itself will melt at the same instant: care must be taken also that all the feet keep in their due places, otherwise the copper will not fit properly, and the feet must either be cut off, and new ones foldered on, or much trouble will be found in drawing the holes of the brass-edges or frames, to get the coppers into their proper central situations.

The copper being thus far advanced is thrown into the pickling-pan, in order to free it from the scale or oxydable covering acquired from the heat. The pickle is either oil of vitriol, sufficiently neutralized for the purpose by water, or else a solution of the best double aquafortis. When the scale is enough softened to admit of its being removed by a soft brush, used with water and a little white sand, the copper is taken out of the pickle, and all the impurities being washed away, it is dried by means of heat, or else with a soft cloth. In this state, the copper will generally require to be again put into a proper shape, by means of the brass die, and setting block, as it is scarcely possible but that some irregularities will be produced through the operations last described. It is also hardened in a slight degree by rubbing the under side with the setting spatula, and the surface with the scratch-brush. When this is done, the copper is completed, and fit to be enamelled on. It is to be remarked, that when many coppers are prepared at once, much time is saved by turning off the edges by means of the lathe and arbour, instead of by filing them even in the manner detailed above.

The above are the methods by which the common coppers are prepared; it is now requisite to describe what are called *French edges*, from their having been first made in France. These are of two kinds, the solid French edge and the laid-down French edge. To make the former, a piece of copper is taken, either about a sixteenth or a twelfth of an inch thick, according to the diameter of the intended plate, and a hole being drilled in the centre, the copper is placed upon an arbour, and fixed tightly by means of a small cone and screw-nut fitted to the maundrel. The arbour being then fixed upon a lathe, the edge of the copper is next turned off in an oblique direction, inclining inwards, with a graver, and the copper is then reduced to the proper thickness for enamelling from the edge to the centre, by means of a scoper and other tools; thus leaving the edge solid, and taking care also that a sufficient substance is left unreduced round the cone, to form the outer circle of the eye. The laid-down French edge is made by preparing a copper in the common way from a thin slip, the edge being left rather higher than usual, and then fixing it upon the arbour, when the edge of the copper being first turned perfectly even with a

## ENAMELLING.

graver, is next forcibly bent inwards by a small triangular tool, (perhaps formed from the end of a three-square file worn smooth,) and afterwards squared and finished by the graver and scratch-brush. It is in general necessary to reverse the coppers on the arbour, and turn a small portion of the under side away, both of the solid and laid-down kinds, in order to make the edge of a due sharpness. The coppers are lastly set up, and the feet soldered on, as before described. French edges are mostly used for watches of a particular kind, where room is wanting, and the dials are fixed upon the frames without a brass-edge.

When a dial is made for a seconds' watch, or for one requiring still more circles than two, the additional eye, or eyes, is made by marking the centres accurately with a point on the under side of the copper, and then bulging the copper upwards with a small punch from each centre, by striking it gently with a small hammer into a piece of lead, about three times the thickness of a die; the lead forms a sufficient resistance to prevent the eye from cracking, and is yet soft enough to admit of the copper being bulged up evenly. The small eyes are afterwards evened with the file, and opened with a small needle or round-pin to the required sizes. Some trivial variations in the mode of making the seconds' holes, &c. occasionally occur.

The coppers being thus prepared, the next process is that of *enamelling*, properly so called. Where the operations of *hard enamelling*, and *glass enamelling*, are dissimilar, the difference will be described in proceeding, but to a certain extent they are the same.

The enamel, as it comes from the makers, is generally in small cakes from four to five or six inches in diameter. In preparing it for use, a small hammer is used, having one end flat, and the other of the shape commonly employed to rivet with. With this the enamel is broken into thin pieces or flakes, by striking the edge of the cake smartly as it rests upon the fore finger of the left-hand. The pieces are then put into an agate mortar, and with a pestle of the same kind are finely pulverized, the splinters being prevented from flying about, by keeping the enamel covered with pure water all the time the process of *grinding* is going on. The point at which the trituration should be discontinued, can only be ascertained from experience, as the different kinds of enamel, and the different modes of its application, require the *ground* enamel to be either more or less fine. In general it may be stated, that the *backing* should be much finer than the *first coat*; the *second coat* of an intermediate fineness; the hard enamels considerably finer than the glass, and the flux still finer than those, as the fire operates with less effect upon the flux than upon either of the former substances. In grinding, great care must be taken to keep the enamel free from dirt, and the light slue which arises must be washed away three, four, or more times, as may be necessary in the course of the operation, till the water comes off quite clear. A small tea-pot is commonly used to pour the water from, and when the enamel is ground sufficiently, the produce is emptied into some other small cup for use, the surface being kept just covered with water.

The manner in which the grinding is performed, is by placing the mortar upon the work-board, on a coarse piece of flannel or linen, twice or thrice doubled, and wetted to prevent its slipping. The handle of the pestle is then grasped firmly about the middle with one hand, and the palm of the other being placed upon the top, the operator inclines the upper part of his body over the mortar, and crushes the enamel by pressing forcibly with his breast upon that hand which covers the pestle. This motion is repeated in quick succession, till all the larger pieces are reduced into

coarse and uneven grains; which grains are afterwards ground to the requisite equality and fineness, by holding the mortar firmly down with one hand, and with the other giving a circular direction to the pestle, using at the same time as much strength as can be conveniently exerted.

In enamelling watch dials, many coppers are usually prepared to go on with at once; that method possessing the three-fold advantage of saving time, materials, and labour. When the enamel is ground, therefore, the coppers having been first cleaned by the pickle, and carefully brushed out with water, are spread, face downwards, over a soft half-worn cloth, or smooth napkin, and a thin layer of hard enamel, called, in its ground state, the *backing*, is spread over the under sides with the end of a quill, properly cut, or with a small bone spoon. The coppers are then slightly pressed on by another soft cloth or napkin, which, by imbibing some portion of the water, renders the enamel sufficiently dry to be smoothly and evenly spread with the rounded side of a steel spatula. The water is then again dried out by the napkin, and a yet further evenness produced by going over the enamel as before, with the spatula, and these operations are repeated, till the back becomes completely smooth, and the enamel is of an equal thickness all over. It must be observed, that the water should not be *entirely* absorbed, as in that case the enamel would fall off, in powder, before the subsequent operations are completed. When the enamel is properly spread, the loose particles are carefully cleared away from the edge and eye of the coppers; from the former by the spatula, from the latter by twirling round it the pointed end of a quill, and the process of *laying the bottoms* is thus finished. Some slight variations to the above method are in use among different artists, but the difference is scarcely important enough to require description. In some instances the enamel is laid on with the spatula itself, and the coppers, instead of being held between the fingers, are placed upon the round pin, by means of the centre holes, till the backs are duly spread: in both modes due care must be taken that the coppers are not bent out of their proper forms.

The next operation is to lay the *first coats*; that is, to spread a layer of *glass* enamel over the upper sides of the coppers. In doing this, the surface is first brushed slightly over with a small camel-hair brush, or a hare's foot, to remove any dirt or extraneous particles of enamel, as the mixture of any hard enamel with the glass would infallibly spoil the work. The glass is then spread upon the coppers in a layer, the thickness of which is commonly the same as the height of the edge and eye. The water is afterwards slightly absorbed with a clean napkin smoothly folded, and the enamel spread by a thin, flat spatula, till all unevenness is removed, and the surface lies regularly from edge to centre. The edge being then gently tapped twice, or thrice at different places with the spatula, the water rises towards the top, and is again dried off by the napkin, when the enamel is once more made smooth by the spatula, and the water being wholly taken up by the napkin, or as nearly so as can be effected, without disturbing the enamel, the *first coats* are placed upon rings for *firing*.

The rings used in enamelling are generally made of a mixture of pipe-maker's clay and Stourbridge clay, rolled up into the form of cylinders, and turned in a lathe by means of a cylindrical piece of wood forced through the centre of the mass when wet. Each ring is about a quarter of an inch in thickness, and the same in depth; the upper side is prepared for use by rendering it slightly concave, which is done by rubbing it carefully upon a half globe of lead sprinkled over with fine silver sand: the under side is nearly flat. Through the concavity thus given to the rings,

## ENAMELLING.

the edge of the copper or dial-plate only is suffered to touch, by which means the enamel on the back remains undisturbed, and the edges are prevented from sticking by rubbing over the surfaces of the rings with soft chalk or whiting.

The first coats having been placed carefully upon the rings, are next put into a shallow tin vessel, called a tin cover, which is either made square or round, according to the fancy of the artificer, and is commonly about three quarters of an inch in depth. All the moisture is then slowly evaporated from the enamel, by placing the cover upon a German stove, or in some other convenient situation near a fire, where the evaporation can be properly regulated: for, should the water be dried off too quickly, the work would be in danger of spoiling from *blebs* or *blisfers*. These are very small air-bubbles, which, by rising to the surface of the dial-plates, destroy their smoothness and beauty. They appear to be occasioned, partly by want of due care in laying on the enamel, and partly by the confinement of the air which the water contained, and which, in the process of firing, becomes rarefied; throwing off, by its expansion, a portion of the surrounding enamel, yet not entirely escaping without a very vivid heat, and even then resolving into black or green specks, so coloured through the oxydation of the copper.

The firing is executed beneath a muffle, placed in a small furnace ignited with coke and charcoal. (See *MUFFLE* and *FURNACE Enamellers*.) The furnace being drawn up to a sufficient heat by means of a register, the first coats are taken separately from the tin covers, and placed upon thin planches of clay, or iron, chalked over, and gradually introduced beneath the muffle; where, in a very short time, the enamel melts, or technically *runs*; and becoming properly consolidated, the first coat is complete. Great attention is requisite in this operation, to prevent the enamel from being over-fired; as in that case, the glass would lose some portion of its opacity, and other defects also be produced, to the detriment of the work. The planches are placed towards the further extremity of the muffle, by means of a pair of spring tongs; and as soon as the fusion is seen to take place, are turned carefully round, in order that every part should be equally fired. The planches are generally made circular, and slightly concave, for the convenience of moving the work without danger of shaking off the enamel before it becomes fixed by the heat.

As all solids, when reduced to a granulated state, occupy a greater space than before, *et vice versa*, it will be found that a very considerable depression has been produced in the enamel of the first coats by the act of fusion; and that the edge and eye are now much above the surface. This deficiency in substance it is the office of the *second coats* to supply. When the work is cooled, therefore, the scale is wholly removed from the edges and eyes by means of a fine-grained Lancashire file, or a smooth grey-stone; and being then washed and dried, each plate is put upon a small round wax-block, of sufficient bulk to be held in the hand, and about four or five inches high. The feet are then either pressed firmly into the wax which covers one end of the block, or the plate is otherwise fixed by means of three small cones of wax placed triangular-wise upon the block; care being taken not to strain the enamel by too weighty a pressure. A second layer of ground enamel is then gently spread with a quill, and prepared for firing by the napkin and spatula as before; after which the second coats are placed upon the rings, and the moisture being evaporated in the tin-cover, (one edge of which, both in this and in

the preceding operation, should be left a little open to give issue to the steam,) they are ready for a second fire.

The second firing requires an equally cautious management as the former one. The plates must not be over-fired, nor must the heat be suffered to melt the enamel too rapidly; but a kind of rotatory motion, called *coddling*, must be given to the work, by holding the loaded planch lightly with the tongs, and gently drawing the edge of it towards the mouth of the muffle, and then returning it to its former place, till the fusion be complete; a proper knowledge of which can be gained only from practice. The work is now in a fit state for polishing.

*Polishing*, in this art, has a twofold signification: it not only means to render bright, according to the common acceptance of the term; but also to make even, without any reference to glossyness. The enamel has a natural brightness of surface acquired from the fire; and when this is removed, it is only necessary again to expose it to a due heat, to cause it to reassume its former character. Yet as this brightness exists independent of evenness, and as evenness is essential to the perfection of enamelling, it is requisite, in most cases, to produce that quality by the methods next to be described.

The materials used in polishing glass plates are grey-stones, rag-stones, sometimes called burrs, fine ground silver sand, and water. The grey-stones ought to be of a fine grain and even texture, without knots, which would be very detrimental by making deep scratches in the enamel, instead of wearing it away evenly. The plates are taken separately, and the thin edges are first worn off by one of the finer grey-stones, till they become smooth and equal; after which the eyes are rubbed down, till the centre of each plate is even and square. Either the grey-stone or the rag-stone is next employed, according to the nature of the work, to wear away all the irregularities that may exist on the surface of the enamel; the rag-stones being only used for the more common kinds of dials. This is done in different ways; *viz.* first, either by holding the plate upon the fore and middle finger of one hand, and giving it a sort of circular motion by means of the thumb, whilst with the other hand the polishing-stone is rubbed with a forward and backward stroke over every part of the surface; secondly, by holding the polishing-stone on the work-board with one hand, and with the other rubbing upon it the face of the enamel; or, thirdly, by fixing the plate upon a cork, either by means of the feet, or with a piece of wet flannel, and with the fingers giving it a kind of rotatory motion, whilst the polishing-stone is rubbed over it in a similar manner. The ground silver sand is used to give sharpness to the polishing-stones, and wear away the enamel with greater celerity than would be otherwise acquired; and the act of polishing is continued till all the gloss is ground off the surface. In this operation great care must be taken that the pressure be not too powerful, as the plates will then crack in the fire, and can never, or very rarely, be properly mended.

When the enamel is sufficiently polished, which is easily known by the criterion of all the gloss being removed, the plates must be clean washed, and the specks of dirt, &c. picked out with a sharp graver. They are then well rubbed over with some fine ground glass, either by means of a cloth, a glass mull, or perhaps a small bit of fir-wood cut smooth, in order to remove the stains that may be left by the polishing-stones; and the clean water being suffered to run over them, they are wiped dry, and again placed upon the rings for firing.

## ENAMELLING.

The degree of heat necessary for polished plates is determined by the finer or coarser modes in which they were prepared; as the fusion is much facilitated by the enamel being free from scratches. When the surface is properly run, that is, when it becomes perfectly smooth, even, and bright, the plate is completed; and when cold, is fit for painting on. See *PAINTING of Clock and Watch Dial-Plates*.

The above description regards more particularly the best kinds of work; but for the more common work there are two other modes of enamelling practised, which it will be requisite briefly to explain. The plates made in these ways are called *run-down plates*, and *run-down second coats*.

Run-down plates are those which are made by laying the enamel upon the coppers in sufficient quantity to form plates of the required thickness, without putting on a second coat. Both labour and fire are thus saved; but that neatness, regularity, and squareness, which are acquired by the first method, are rarely obtainable in this: and indeed flat plates can hardly be managed at all in this mode. Run-down plates require more coddling than any other; and a longer continuance of vivid heat is necessary to make the glass flow to a proper evenness of surface: the plates being wholly completed with one fire, and without polishing. It is obvious that the most common work only can be thus manufactured; for that of the next superior description, the run-down *one coats*, are polished off with the rag-stone, and undergo a second firing. The run-down second coats are those which are reduced to a surface comparatively even by the second fire, and are then painted on without being polished off.

In enamelling *hard-plates* for watches, the coppers and the first coats are prepared in the manner above described; excepting perhaps that the layer of glass is rather thinner than in glass-work only. The hard enamel, which is generally most valued as it approaches to a rich cream colour, is broken down, and ground in the same way as the glass, if a small quantity alone be wanted; but if otherwise, it is first broken from the cake with the hammer, and then pounded in a steel mortar, till reduced into coarse grains. These grains are then exposed to the action of a magnet, in order that all the particles of steel that have been broken off the mortar in the act of pounding may be taken away, as they would infallibly spoil the work, by rising in black specks to the surface of the enamel, when in the fire. As an additional precaution, also, it is necessary to put the granulated enamel into a small basin, and pouring upon it a strong solution of oil of vitriol, or aquafortis, to suffer it to stand for some hours, that the steel particles, &c. may be wholly dissolved; after which, the enamel must be very carefully washed, till the water comes off pure and tasteless: for should any of the acid remain, the work would certainly blister. The enamel is then ground to the necessary fineness in an agate mortar, and afterwards spread over the first coat with a quill, in small quantities, and as evenly as it can be laid, that it may require the use of the spatula as little as possible. The water is then partly absorbed by a very fine and clean napkin, and the enamel smoothly spread and closely compressed with the spatula; after which, more water is absorbed, and the spreading is continued till the surface lies true and equal. The plate is then put upon a ring, and properly fired; and is afterwards polished by placing it upon a cork, (the top edge being first taken off with a fine grey-stone,) and wearing away the surface, first, by a very fine-grained Lancashire file, or smooth piece of steel, and silver sand, ground to an almost im-

palpable powder; secondly, by a fine blue-stone and sand; and thirdly, by the blue-stone alone. With the latter a sort of half-polish should be given to the enamel; and the nigher that polish approaches to complete glossyness, the better; as the plate will then be finished in the third fire with a less degree of heat than would be otherwise wanted: In this process, much caution is required to prevent scratches, which cannot be *run up* by the fire without giving the enamel a greater heat than it will well bear. When the polishing is completed, the plate is carefully cleaned with ground enamel; and should there be any specks, they must be picked out with a small and sharp diamond, and the hollows very dextrously filled up with enamel from a quill-point, that they may neither rise above or sink below the common surface, when the plate is again fired: should they actually do so, they must be made smooth with a blue-stone, and the plate must undergo a fourth fire, to render the surface of one uniform texture and glossyness. Hard-enamel dials are always considerably dearer than glass ones, through the greater labour, attention, &c. that are requisite in making them; and the best watches are almost always made up with dials of this kind.

In the polishing off both of glass and hard plates, much address is necessary to prevent a separation between the enamel and the edge of the copper; for if too great a pressure is exercised, or if the grey-stones, which are employed to wear down the copper, are of too rough a grit, the adhesion will be destroyed, and various black indents arise round the edge of the enamel, when the plate is again exposed to the fire. In glass dials, these defects may be sometimes amended; but in hard-enamel dials, scarcely ever.

The operations of *transparent enamelling* are nearly similar to what have been already described in the making of watch dials. As the work is generally of a more minute kind, greater delicacy of handling perhaps is required; and as the enamels are of various colours and descriptions, more cups, vessels, &c. and additional soft cloths or napkins, are wanting to keep them from mixing. Watch cases are commonly enamelled upon gold, as well as most superior articles of the fancy kind; and the surface of the gold is frequently engraved into different figures and compartments, before the enamel is laid on; by which means the work assumes a beautiful variegated appearance through the vitreous coating.

In enamelling the backs and edges of watch-cases, &c. quince-water is frequently used as the medium by which the enamels are laid on; for this possessing a more adhesive and retentive quality than common water, better prevents the enamel from flowing from its proper situations: for where the convexity is considerable, the enamel will of course have a tendency to float towards the lowest part. When enamels of different colours are intended to be employed on the same article, which is frequently the case in ornamental works, small edges or prominent lines are left in the substance of the metal, for the purpose of keeping the enamels separate; and these are polished with the enamel, and reduced with it to a similar equality of surface. Transparent enamels are not unfrequently polished to complete glossyness, without exposing them to an additional fire: in these cases, the work is finished with rotten-stone.

It is sometimes desirable to take off the enamel from a watch-case or trinket, without injuring the metallic part. For this purpose it has been recommended to lay a mixture of common salt, nitre, and alum in powder, upon the enamel requiring to be removed; and afterwards to put it into the furnace: and when the fusion has commenced, to throw

## ENAMELLING.

throw the case, &c. suddenly into water, which causes the enamel to fly off in flakes.

In ornamental transparent work, a very pretty effect is often produced by applying small and very thin pieces of gold or silver, cut or stamped, into different figures, as acorns, oak-leaves, vine-leaves, bunches of grapes, fruits, &c. upon the surface of the first coating of enamel, where they are fixed by the fire; and are afterwards covered over by the second layer, through which they appear with considerable beauty. When any quantity of fancy-works of similar design is wanting, this mode of enamelling is much cheaper to execute than to have the surface of the metal itself engraved into the required forms.

*Clock Dial-Plate Enamelling*, is far more laborious than the other branches, and requires considerable experience to be properly executed, though the methods of operation are soon explained. The copper, being procured from the flattening mills in thin slips, and of an adequate diameter and thickness, is cut to nearly the required size with a pair of strong scissars, a circle having been first struck with the compasses. If in a soft state, it is then cleaned by the pickle, and having been brushed out with sand on a flat board, is washed and dried for planishing; if otherwise it must be well annealed before it is thrown into the pickle, where it must lie till all the scale is enough softened to be removed by the hand-brush, sand, and water.

*Planishing* is a very important part of clock-plate enamelling, and too much care cannot be exerted in the process, as the necessary regularity of surface almost wholly depends upon it. In large plates the action of the fire has a very considerable effect, as it causes an expansion in the metal, which, unless properly guarded against, cannot but operate to the imperfection, and perhaps total spoiling of the work. In flattening also, a sort of twist is not unfrequently given to the copper, during its passage through the rollers, that would assuredly cause the plate to become uneven and out of shape, were it not to be removed by planishing and repeated annealings. Another effect produced by the fire, is occasioning the plate to rise, perhaps irregularly, towards the centre, and this can only be checked by counteracting the action which the heat would otherwise generate in the metal by good planishing. To keep a large plate entirely flat is impossible; or at least no means have as yet been discovered through which that aim can be attained. The best way, therefore, to provide against the irregularities which the fire might cause, is to give to the copper, in the course of planishing, a slight and even rise or curve from the edge to the centre; this can either be effected by the use of large brass dies, or by a machine adapted for the purpose.

The *machine* of which, probably, there is only one in the trade, consists of two principal parts; the one a solid mass of iron, with a concave and polished face, imbedded immovably in a strong oak block, firmly fixed on a foundation of brick-work, and the top edge hooped with a thick iron ring, to prevent splitting; the other, an answering and weighty mass of iron with a convex face, similarly polished, and fixed in an upright frame of timber, but so contrived as to become *moveable* by means of sliding grooves, a rope, a pulley, and a lever, and so placed as to fall directly upon the mass beneath, in a similar way to the monkey of a pile-driving engine. The diameter both of the hammer and the anvil, as the upper and under masses of iron may be called, for the sake of perspicuity, is about thirteen inches; that size being nearly as large as clock dials are ever made or wanted. The convexity of the hammer is exactly fitted to the concavity of the anvil, and may be described, perhaps, as forming a portion of a circle fifty feet in diameter; and the

centres of both are kept true to each other, and consequently to the regularity of curve, by means of large screws and nuts, which adjust the position of the hammer by altering the perpendicularity of the bars of iron that the grooves act upon. The power of this machine saves much labour in planishing, as well as time; yet as it is insufficient wholly to prepare the coppers, and as the charge of erecting one would be very considerable, it will never, perhaps, come into general use.

In planishing with this machine, it is necessary to be provided with various thin circular pieces of lead, evenly flatted, and adapted in size to the diameters of the coppers to be planished. Without these the stroke given by the hammer would have a very imperfect effect; and the impulse given by the weight of its fall would also be continually weakening the foundation and bed of the anvil.

The coppers prepared for planishing by this machine are taken separately, (the eyes having been previously cut out to a proper size by means of an iron punch, an hammer, and a lead block,) and each one is laid upon a lead of a correspondent diameter, and placed upon the anvil in such a manner that all the centres agree. The hammer, which has been hitherto retained at some height by an iron stay fixed in one of the timbers, and moving on a pivot, is then let fall, three or four times in quick succession, it being each time lifted up to the height of three feet or more, by means of the lever. The hammer is then again fastened by the stay, whilst the copper is turned over on the lead, after which the operation is repeated, and the copper is then taken off, and another laid down till the whole are gone through. The weight of the hammer, and the impetus acquired by its descent, remove most of the unevennesses in the coppers, yet cannot entirely remedy them: a strong and unequal spring will still be felt, and the metal being now rendered hard by the action of the hammer, annealing must again be resorted to, and the coppers must be pickled and cleaned as before. The machine is then used a second time in a similar way; and afterwards a third, a fourth, a fifth, and even a sixth and seventh time, according to the diameters of the coppers, or to the refractoriness of the metals, due care being taken properly to anneal and pickle them between every operation.

The coppers will now be found of a regular shape, and the spring in the metal tolerably uniform; it is essential, however, to the perfection of the plate, that the spring should be *entirely* uniform from edge to centre, otherwise the plate would warp and cockle in the fire. A kind of intermediate process must therefore be carried on between the taking the coppers from the machine, and before repeating the annealings. This is performed by means of a circular brass die, about a quarter of an inch in thickness, and from fifteen to eighteen inches in diameter, screwed firmly down to a strong oaken block, having three stout legs, placed triangular-wise, and of a sufficient height to use conveniently when the artist is in a standing posture. The die should have the same degree of curve as the machine, otherwise the effect produced by each would occasion a sort of reciprocal counteraction. The coppers, having passed through the machine, are placed in succession upon the die, and a wooden box-hammer (somewhat resembling that used by gold-beaters) with two faces, the one a circle about three inches over, the other cut away on the front edges, so as to leave only a portion about an inch or an inch and a quarter in breadth remaining in the middle, is then taken, and the copper is both rubbed and struck with it till the metal becomes too hard for any further impression to be made, and requires annealing. The circular end is used to strike the copper

## ENAMELLING.

copper with, which is done by short, quick beats of the hammer, the artist working from centre to edge, and communicating the necessary motion and direction to the coppers by means of the fingers of one hand, so extended over the work as to give the requisite command in guiding it: the other end is employed in rubbing the coppers strongly with a backward and forward action, under which they are moved upon the die by the fingers as before. Where the machine is not used, the planishing must then be entirely performed in the way just described, and great care must be taken, that in the rubbing, the coppers be not beat, which would occasion both additional labour, and further annealing. No positive direction can be given as to the number of times that the coppers must be annealed in the course of the planishing; as a general rule, it may be said that the larger the size, the more frequently must the annealings be repeated. For plates of from three to four inches, twice or thrice is commonly enough; from five to eight inches, about four or five times are requisite; for larger sizes, the annealings must be continued till the spring or action in the metal becomes uniform, as already mentioned. This is best determined by the regularity with which the copper will flap or jerk into the curve given by planishing when turned either side uppermost upon the die. When the planishing is completed, the coppers are cut exactly to the sizes required, and having been pickled and cleaned, they are then ready to be enamelled on. After the last annealing, it is best to planish but slightly, that the coppers may be left in a state of comparative softness.

For time-pieces, table clocks, and some others, *round* plates are commonly used, and in these cases it is necessary to have moveable brass dies formed into the curves required. Round plates are those which have a considerable rise in the centre, made by a pretty quick forcing up of the copper into a sort of shoulder about where the circles of the hours come, and afterwards continuing the rise more gradually. The bent spatula and the scratch brush are chiefly employed to set the coppers into these curves, and where the rise is very quick from the edge, the copper is sometimes turned up as in small dials, that the enamel may be the better retained in its place.

The quantity of enamel wanting for clock dials renders the grinding it a very laborious and tedious operation; especially as the hard kind only can be used with complete certainty. It is true that plates of from ten to twelve inches diameter have been made with glass enamel, where particular attention has been given to the *annealing up*, and to the *cooling down*, (phrases that will be presently explained,) and where the backing has been of a quality perfectly agreeing with the nature of the glass. Of the experiments made in this way, however, the success has not always been proportionate to the loss, and the few enamellers who have clock-furnaces cannot always be induced to repeat them.

The enamel for clock dials is broken down in a steel mortar, and afterwards cleaned and ground in an agate mortar, in a similar way to that prepared for watch plates. Sometimes, where the enamel is of a good quality, the *washings* are made use of for backing, and no bad consequence results, but this requires considerable care in the laying on as well as in properly drying, in order to prevent the surface of the back from rising in blisters, either entirely or partially. Washings is the name given to the almost impalpable powder which arises in grinding, and floats in the water, intermixed with the dust and minute hairs which are sure to fall into the mortar, and which renders it necessary that the enamel should be several times washed during the process by pouring off the buoyant matter from time to time, and introducing

fresh water, from the tea-pot. Pure spring water ought always to be used, and a large basin provided for the reception of the washings.

In the best and largest kinds of work, the washings ought never to be used, as their great propensity to blister can hardly be counteracted; and when the blistering is considerable, the plates will assuredly *cockle*, or get out of shape. The peculiar fineness of the washings, also, occasions it to be very difficult to lay on as backing in an even manner. Where the enamel in substance only is used, the success of the work is rendered more certain; the additional expence therefore is fully balanced by the greater security.

The general way of putting on the enamel is to lay the copper upon a cloth, twice doubled, and placed upon a die or piece of board, for the convenience of turning. The backing is then spread carefully over it by means of a small ivory or bone spoon, and when the whole surface is covered, the water is partially dried off by another cloth, and the enamel laid even by a large spatula, (see *SPATULA*,) finely polished. These operations are repeated till the back surface is sufficiently evened and dry; when the copper is turned, and the first coat laid on and evened in a similar manner. The work is then placed upon a planch for firing, and is next put into the annealing places in the upper part of the furnace, (see *FURNACE for Clock-Dials*,) where the humidity is gradually evaporated as the fire draws up. The planches are from a quarter of an inch to three quarters in thickness, in proportion to the size, and are either made of fine free-stone, or of a composition of Stourbridge clay, pipe clay, and *old stuff*, as the broken muffles, planches, &c. are called, pounded together in an iron mortar, and passed through a coarse sieve. The face of each planch is either flat or rubbed into a similar curve to that given to the coppers, and before the work is put on to it, a slight covering of whiting, dried, is sifted over it, through a small brass-wired sieve: this is done to prevent the enamel from sticking to the planch when in the act of fusion.

The muffle is *got up* or rendered hot with sea-coal, and when sufficiently vivid, which is known by its near approach to a white heat, the first coats are taken from the annealing holes by means of iron prongs, which are slid beneath the planches by a steady and careful motion, lest the enamel should be shook whilst in powder; to prevent this, also, a farther provision is frequently made by means of *irons*, as they are called in the business, which are placed below the planches, and having a round form, and a convex bottom, are extremely useful in moving the work, by admitting the prongs to be readily passed below them. The irons are adapted to the size of the planches, and are formed out of thin iron plates, and are cut into a circular shape; some portions of the metal, to render the irons less weighty, being wholly removed from between the rim and the centre, which from this circumstance appear to be connected by cross bars.

When the first coats are properly fired, which can only be determined from practice, they are replaced in the annealing holes, and there left for some hours to cool down, all the fire having been first raked out from the furnace. The operation of cooling down must be effected in a very gradual manner, for were it done too quickly, the plates would crack in different places, through the action of the metal upon the enamel. The particular cause of this cracking seems to arise from the surface of the enamel being too suddenly fixed by the cold air, to admit of that gradual adjustment to the contraction of the metal, which the latter, by retaining the heat longer than the enamel, renders necessary. On a similar principle, the annealing up of the second coats must be equally progressive; for should they be too suddenly

## ENAMELLING.

suddenly put into the fire, the metal, by expanding with the heat before the fusion of the enamel has commenced, would cause the enamel to fly through its brittleness, and the surface would be thereby streaked with cracks.

The enamel for second coats, as in watch plates, must be ground finer than for first coats, yet not so fine as for backing. It is laid on with a spoon, and reduced to a smooth and equal surface by the spatula, in the same manner as above described; and the plate being enamelled with the requisite attention, is fired a second time, and gradually cooled down as before. The next operation is polishing.

Clock plates are polished by a somewhat different process than watch dials. When perfectly cold they are taken off the planches, and either carefully fixed upon a bed of wet sand, so that not any hollow or vacancy is left below the plate, or imbedded in a similar way with sand upon wet flannel, twice or thrice doubled. When thus prepared, the surface is gradually worn even by means of fine silver sand, passed through a sieve, that the coarser particles may be prevented from scratching the enamel, and polishing-stones formed of flint pebbles, ground at one end to a regular surface. The sand is used with water, and the operation is performed by giving the polishing-stone a quick circular direction in progressive movements over every part of the plate, till the surface is evenly reduced, which is known by the glossiness being wholly worn off: this occupies from half an hour to an hour, or more, according to the size and previous evenness of the plate. Sometimes the polishing is accelerated by using pieces of lead or iron, as half-pound weights, for instance, in the early stage of the process, and afterwards finishing with the flint; and that not only to give a smooth surface to the enamel, but likewise to remove the general stain or blackness which proceeds from the use of the lead or iron. When the polishing is completed, the plates are well washed and brushed, and afterwards made perfectly clean by some fine enamel being ground over the face of each with a small mull or polishing-stone for about a quarter or half a minute; the operation being repeated twice or thrice, as may be necessary, and the loose enamel being carefully wiped off with a smooth cloth or napkin, after the last cleansing, instead of being washed away: this is done in order that the small pores which are sometimes laid open by polishing into the substance of the plate, may be filled up by the minute particles of enamel that escape the action of the cloth, but would be removed by the water. Whatever specks or blisters may be in the plate, are then opened with the diamond, and the holes neatly stopped with finely-ground enamel from a quill-point, as in watch-plates; the *stoppings up* being suffered to lie rather higher than the surface, to admit of the reduction in bulk occasioned by the fusion. The plates are now again put into the annealing places upon the planches; and the furnace being properly heated, are fired for the third and last time, before painting. In this latter firing, great care should be taken that the enamel be not over-fired, which would occasion a freckled appearance in the plate, when held against the light; and if the work is drawn out from the muffle after the fusion has commenced, and again returned to complete it, the air will be found to have given additional richness to the glossiness of the surface. The precise time required for firing polished plates can only be known from practice; those on which the finest polishing-sand was used, and, of course, where the scratches are less deep, wanting less heat than when the sand has been employed in a rougher state. After firing, the finished plates are returned to the annealing-holes, and gradually cooled down for painting on. See *PAINTING of Clock and Watch Plates*.

In the making of *fluxed plates* for enamel-paintings, similar methods of planishing are practised to those already detailed; and similar or even increased care must be taken in destroying or regulating the spring of the copper. Fluxed plates are commonly either square or oval: in the square ones, about an eighth of an inch, or somewhat more, should be cut off each angle of the copper, previous to enamelling, to prevent the danger of breaking them. In preparing them for the flux, every thing is conducted in the same way as for clock-dials, till they are polished off, when, instead of firing them in their polished state, the flux is laid on as a third coat. In grinding the flux, very particular attention must be given to keep it free from dirt; and the grinding must be continued till the flux becomes extremely fine, as it will not otherwise flow to an even surface, when exposed to the fire, without a more intense heat than the substance will well bear. The flux indeed requires a peculiar delicacy of treatment, and the firing of the fluxed plates must be managed with great caution and nicety. The heat which they require in fusion is much stronger than that for enamels only; but the exact point of time for withdrawing them from the furnace must be dexterously seized, lest the flux should fall into freckles. It is not customary to polish off the flux, as by so doing it would be deprived of some portion of its brilliant richness; yet that perhaps would be in some measure compensated for, by the superior evenness that would be attained. Fluxed plates must be cooled down with great care, as the brittleness of the upper coating renders them more liable to crack when too suddenly made cool. In fluxing, hard enamel must always be used; as the flux will not agree with glass enamel, but cracks in circles as it grows cold. See *FLUX*.

The greater ductility of gold, and its superior mellowness of colour, render it by far the best metal that could be employed for the basis of fluxed plates; though, on account of the expence, it is seldom used. For naked figures, portraits, or other subjects, where much flesh is exhibited, gold plates ought to be exclusively employed, as their rich hue would save considerable labour in the painting.

Till the present age, fluxed plates were seldom made of a larger size than four or five inches; but since the art of enamel-painting has been carried to such great perfection by Mr. Bone, enamel-painter to the king and the prince of Wales, they have been progressively increased in extent for his use, and are now made of every size up to twelve and fourteen inches. The largest ever completed measures eighteen inches by sixteen and a half; and Mr. Bone is now employed in painting it from Titian's famous picture of Bacchus and Ariadne, in the collection of lord Kinaird. See *PAINTING on Enamel*.

In chusing enamels for use, great experience is necessary: indeed the most expert practitioner may be deceived, unless he make the requisite trials by aid of the furnace. Some enamels can only be employed alone; others may be used for the upper coats, but require a stronger kind for the backs; and some can be used only for backing. Should a new sort be proffered for use, experiment alone is the criterion by which its qualities can be determined. In a similar manner, some fluxes will only agree with particular enamels; others must be used separately; and others again must be mixed in grinding, before they can be employed with certainty.

In every branch of enamelling, it is essential that the copper, or other metal employed to enamel on, should be of a proper thickness. Should the metal be too thick, the plates will always crack, either in their second coats, or in their polished state; and should it be too thin, they would

be extremely likely to warp from the too powerful action of the enamel. The due medium can only be ascertained by practice; for even the different kinds of enamel will require a difference in the thickness of the metal.

The proper management of the fire; and the mode by which the muffle is heated, will be explained under the words FURNACE and MUFFLE; it need only be stated here, that the time necessary to get up a clock furnace varies from about an hour and a half to two and three hours, or more, according to the intensity of the draught, the method of stoking, and the quality of the fuel. The work is turned in the muffle by means of spring tongs, so that each part may have a regular and due heat; and it is returned into the annealing places with the prongs. Should many plates be fired at one time, the labour will be found to be very severe, and the heat too powerful; as it carries a flux of blood to the head, and occasions languor and oppression throughout the whole frame.

ENAMELLING Flux. See FLUX.

ENAMELLING, Imitative. See JAPANING.

ENAMELLING Muffle. See MUFFLE.

ENAMELLING Spatula. See SPATULA.

ENARA, in Geography, the chief lake of Lapland, in the northern extremity, about 70 British miles in length by 30 at its greatest breadth.

ENAREA, a province of Abyssinia, conquered by the troops of the Negus, at the beginning of the 17th century, situated at the S.W. extremity of the empire.

ENARGEA, in Botany, from *εναργεια*, conspicuous, or distinguished, alluding doubtless to the striking and elegant appearance of the plant, so little to be expected in the dreary country about the Straits of Magellan, of which it is a native. Banks in Gært. v. 1. 283. t. 59. f. 3. Schreb. 232. Willd. Sp. Pl. v. 2. 230. Mart. Mill. Dict. v. 2. (Callixine; Juff. 41. Lamarck t. 248. f. 2: also, Philesia; Juff. 41. Lamarck t. 248. f. 3. Willd. Sp. Pl. v. 2. 231.) Class and order, *Hexandria Monogynia*. Nat. Ord. *Sarmentacea*, Linn. *Asparagi*, Juff.

Gen. Ch. Cal. none. Cor. Petals six, erect, elliptic-oblong, acute, inferior; three of them exterior; three interior, larger. Stam. Filaments six, shorter than the corolla, equal, awl-shaped, dilated at the base, slightly attached to the bottom of each petal; anthers oblong, versatile, incumbent. Pist. Germen superior, globose; style the length of the filaments, erect, swelling, and triangular upwards; stigma in three obtuse lobes. Peric. Berry globose, of three cells. Seeds angular, three or more in each cell.

Ess. Ch. Calyx none. Petals six, erect; three of them internal. Stigma three-lobed. Berry superior, with three cells and many seeds.

1. *E. marginata*. Gært. as above. Willd. Sp. Pl. v. 2. 230. Petals nearly equal. Leaves with many ribs.—Our specimens of this pretty little plant were, some of them, gathered by Commerçon in the Straits of Magellan, and communicated by the celebrated M. de Jussieu; others by Mr. Archibald Menzies in Staten land near Cape Horn, in Feb. 1787, all of them in blossom. Lamarck's figure is a tolerable representation of the whole plant, except the stigma, which he erroneously draws simple and entire. His fruit is copied from Gærtner.—The roots are creeping, and throw out clusters of branched fibres. Stems a span high, erect, branched, angular, destitute of pubescence, as is the whole herb; branches zig-zag, leafy, sheathed at their base. Leaves alternate, nearly sessile, upright, about half an inch or more in length, elliptical, acute, entire, somewhat re-

volute, their edges rough with minute spines; their underside marked with three or five strong prominent ribs; the upper even. Flowers terminal, solitary, drooping, on short simple stalks. Petals white, ribbed; the three outermost elliptical; the rest rather broader and obovate; each of the six is said by Gærtner to be marked with two green spots below the middle. Commerçon describes three of them only as having a pair of obsolete glands at their base. Berry the size of a pea.

2. *E. buxifolia*. (*Philesia buxifolia*; Willd. Sp. Pl. v. 2. 231.) Inner petals thrice as large as the outer. Leaves with numerous transverse veins.—Commerçon alone seems to have found this fine species, in the Straits of Magellan. Lamarck's plate, drawn from one of his dried specimens, is a very just representation. We have received several of these from Thouin and Jussieu. The shrub is two or three feet high, with the aspect of box, much branched and smooth. Leaves stalked, an inch long, elliptic-oblong, pointed, revolute; green, smooth, with a longitudinal furrow above; glaucous, with a central prominent rib, a marginal one at each edge, and numerous transverse veins, beneath: their edges are rough with minute teeth near the point. Flowers terminal (not axillary), large and very handsome, apparently reddish; their three outer petals elliptical, flat, about half an inch long; the three inner obovate, thrice as long; all veiny. We presume to unite these two plants under one genus, the differences described in their stigmas having no foundation in truth, and there being a sufficient difference between the outer and inner petals of the first, to shew that a more striking difference of the same kind in the second can only make a specific, not a generic, distinction. S.

ENARGIA, *Εναργεια*, in Rhetoric, a figure, which passing from the narrative style, points out, and as it were, sets the subject before the eyes of the audience. Voss. Rhet. lib. iii. p. 361.

ENARTHROSIS, in Anatomy, is that kind of joint, in which a rounded head of one bone is received into a cup-like hollow of another. See DIARTHROSIS.

ENBAR, in Geography, a town of Asiatic Turkey, in the Arabian Irak, on the Euphrates; 40 miles west of Bagdad.

ENBORNE, a parish in the hundred of Kentbury, Eagle, Berkshire, England, is situated 59 miles from London, and contains 46 houses, and 275 inhabitants. A remarkable and well-known custom is attached to its manors, that if the widow of a copyholder should marry again, or be guilty of incontinency, she forfeits her free-bench, or life-interest in her late husband's copyhold; which is not recoverable but by her submitting to ride into court upon a black ram, repeating some ludicrous lines, which end with a petition for her husband's land. The steward of the manor is then obliged to reinstate her. At every court, the jury still present this as one of the ancient customs of the place. The penalty has not been literally enforced within the memory of man; but it is said, that a pecuniary commutation has been received in lieu of it, which may perhaps have been more readily accepted, from the difficulty of procuring a proper animal for the purpose. Lyson's Magna Britannia, vol. i.

ENCÆNIA, *Εγκαινια*, a Greek term, signifying re-*stauracion*, or *renovation*, being compounded of the preposition *εν*, and *καινος*, *new*.

ENCÆNIA is more particularly used for the name of a feast celebrated by the Jews on the twenty-fifth of the ninth month, in memory of the dedication, or rather purification

of the temple, by Judas Maccabæus, after its having been polluted and plundered by Antiochus Epiphanes.

The Jews had also two other Encænia, *viz.* the dedication of the temple by Solomon, and that of Zorobabel, after the return from the captivity.

ENCÆNIA is likewise applied in the *Fathers*, and *Church-History*, to the dedication of Christian churches. See DEDICATION.

Our translators of the Bible do not retain the word Encænia, in St. John, x. 22. where mention is made thereof; in lieu of that, they call it "Feast of the Dedication," which is less proper. In effect, it is not the feast of the dedication, but of the purification or re-consecration of the temple profaned, that is there spoken of.

St. Augustine assures us, that in his time the use of the word Encænia was even transferred to profane matters; and that they called it *Encæniare*, when they put on a new suit of clothes.

ENCALYPTA, in *Botany*, from *en*, and *καλυπτω*, covered or veiled, alluding to the extraordinary size of the calyptra or veil, which is a characteristic mark of the genus. Extinguisher-moss; Schreb. 759. Hedw. Sp. Musc. 60. Sm. Fl. Brit. 1180. Turn. 17. (Leerfia; Hedw. Fund. v. 2. 88. Bryum; Linn. Gen. 564. Juff. 11. Hudf. 474. Dill. 338.) Class and order, *Cryptogamia Musci*. Nat. Ord. *Musci*.

Gen. Ch. Male, *Flowers* axillary, composed of imbricated scales. Female on the same plant. *Fl.* terminal, several abortive. *Capf.* stalked, cylindrical, inclining to ovate, erect, regular. *Fringe* simple, of sixteen linear, upright, thin, palish teeth. *Veil* bell-shaped, inflated, membranous, much wider than the capsule, erect, often toothed or fringed at the edge.

Ess. Ch. Capsule cylindrical. Fringe of sixteen linear upright teeth. Veil bell-shaped, inflated, lax.

This is but a small genus, consisting of five species only in Hedwig's Sp. Musc. and of four in the Flora Britannica, to which indeed a new one, *E. alpina*, is added in Engl. Bot. t. 1419. The most common is *E. vulgaris*. "Veil entire and smooth at its margin. Stem nearly simple. Leaves lanceolate." Figured in Engl. Bot. t. 558. (*Bryum extingtorium*); and by Dillenius in his t. 45. f. 8. It occurs not unfrequently on shady banks, and in the crevices of rocks, and is strikingly distinguished by its large and deep veil. *E. streptocarpa*. "Veil contracted and torn at its margin. Stem branched. Leaves oblong. Capsule spirally furrowed." Is the largest and finest species, long much misunderstood by botanists. See its figure in Hedw. Sp. Musc. t. 10. f. 10—15, and Haller's Hist. t. 45. f. 3. Dillenius exhibits the leaves and stem only, t. 43. f. 71.

Mr. Turner, in his *Muscologiz Hibernicæ Spicilegium*, suggests an opinion that this genus is not really distinct from *Grimmia*, and we confess that *E. Daviesii*, Engl. Bot. t. 1281, seems not very justly referred to it. It is certain that the fringes of several *Grimmiæ* have the thin pale aspect supposed essential to *Encalypta*, but their veils are truly those of *Grimmia*.

ENCAMPMENT, in *Military Affairs*, implies the position taken for the night, or for any time, of an army, for the purposes of exercise, or for warfare. It is common in all countries for the regular forces to be called out, at stated periods, especially during favourable seasons, from their barracks or quarters, in order to unite for their acting in concert upon a large scale, and for their being reviewed by some superior officer. These camps are usually pitched on certain large commons, whereon evolutions may be con-

veniently performed by several regiments or brigades, and whose sites are favourable both in regard to salubrity, and the easy supply of water and provisions. When we speak of encampments in a literal sense, we invariably attach thereto the idea of living under canvas; and such is absolutely the case, when troops are called out for the above purposes. But we are not to conclude that in time of war, when on actual service, such takes place on all occasions: far otherwise, for it is a general maxim always to spare the camp equipage, as far as may be practicable; and to keep every thing packed, which is not immediately in requisition: therefore, we usually see regiments, especially of infantry, stationed in towns, with lines of pickets in advance, and along their intervals, when the distances between such towns may not be great, and the enemy not so near at hand as to render such breaks dangerous. Thus, an army of 40,000 men is frequently seen to occupy full 20 miles, or even more, in this manner; the different regiments occupying the several villages along that line, and closing up into more compact arrangement, whenever danger may be apprehended. This manner of disposal not only saves infinite trouble and delay, respecting the camp equipage; but exposes the army less to inclement weather, or to noxious localities; and besides, facilitates its movements very considerably, by allowing the whole to move in separate columns, from one station to another. In this the columns necessarily act nearly parallel, much the same as in the advance of a battalion by the right or left of companies in open column.

Encampments, by which we mean the mode of laying out the camp into streets and divisions, are, with some trifling variation, formed after the same manner in all countries. The general principles are, 1st, That no more ground should be occupied than may be absolutely necessary for the drawing up the troops in order of battle: hence, all additions whatever should be made rather in the depth than in the breadth of the camp. This is done to avoid such breaks as could not fail to weaken the line, and to admit the incursions of the enemy's horse. It is, however, usual to allow the interval of about an eighth of their respective fronts between battalions of infantry, and of 30 or 40 paces between squadrons of cavalry. 2dly, The leaving of passages, or streets, throughout, so that bodies may move from one part to the other without hindrance, and without being compelled to pass along the front of the bells of arms. 3dly, That due precaution should be taken for the prevention of disease, by a judicious arrangement of the regimental and general hospitals, as well as by securing the due facility for the removal of filth, and for abundant ventilation; both which can only be effected by due care founded on the precaution of not allowing the camp to be too crowded, either by its situation, or the number of persons contained therein. It is usual to allow a front of two feet for every file (whether two or three deep) of infantry, and a front of three feet for every file of cavalry: hence camps, wherein the battalions are formed three deep, must have their streets full one-half deeper than where the corps are drawn up only two deep. When the ground may permit, the streets are usually at right angles with the front; each row of tents containing the men of a company, arranged according to their several stations, or numbers, in their companies respectively. Supposing the whole to be standing at the doors of their respective tents, and to be ordered to fall in, they would, by this arrangement, arrive in regular succession, either from right to left, or from left to right, at their several stations. The horses and the tents of a troop of cavalry are arranged in a similar manner. The grenadiers and light infantry are ordinarily encamped in single rows,

admit of in one row; then the number of rows being multiplied, by the breadth of one in front, will give that part of the front to be occupied by the rows; and the difference between it and the whole front allowed for the battalion, or squadron, will be left for the streets; which, if the streets are to be equal, must be divided by their number, to find the breadth of each; or is, otherwise, easily divided into streets of unequal breadths.

When two guns are attached to a battalion, they are posted on the right in the following order; from the right of the battalion to the centre of the first gun, four yards; from this to the second gun, six yards. The muzzles of the guns in a line with the serjeants' tents. The subalterns of artillery, if any, in a line with the subalterns of infantry; the rear of the gunners' tents in a line with the rear of the battalion tents.

The park of artillery should always be placed, if practicable, within a short distance of water carriage, and have the most ready communication with every part of the line. Its form must depend on its situation. Ten feet are usually allowed in front for one carriage and its interval, and about fifty yards from the hind wheels of the front row to the fore wheels of the second: this interval should allow sufficient room for putting the horses to the carriages, and for a free passage along the line. In parks not on immediate service, it is usual to arrange the guns with their muzzles to the front, but where the guns are likely to be wanted at a short notice, appearances must give way to promptness, and the gun-carriages must be parked with their shafts to the front, ready to receive the horses, or other draught animals.

A quarter-guard is placed in front of the park, and the non-commissioned officers' and gunners' tents on the flanks, at about twenty paces distant; forty paces to the rear are the subaltern officers' tents; at ten more the rear of the captains; and ten more to the front of the commanding officers: the mess-tent is fifteen paces in rear of the line of officers. At a convenient distance, in the rear of the whole, are the horses, picketed in one or more lines, with the drivers on their flanks. The horses are sometimes picketed in lines perpendicular to the front of the park, and on the flanks of the carriages, between the men and the carriages.

An army is sometimes encamped in two, or even in three, or more lines; according to its numbers, and the nature of the ground. The distance between two lines must depend entirely on local circumstances, or on the object in view: sometimes they are not more than two hundred yards asunder, and sometimes full five or six hundred; occasionally they are pitched in reverse, especially when covering a convoy that has taken post between two hills, or rivers, or woods; in such instances they are "in reverse," and, in lieu of rear guards, have a central force to act as a reserve.

With respect to the choice of ground for an encampment, it must be recollected that no position is tenable, in a military point of view, which does not stand exempt from the enfilade of an enemy. In fact, all commanding grounds ought to be beyond the reach of cannon, so that the camp should not be subject to molestation from such situations. Four principal objects demand attention in the choice of a position for encampment. 1st. The advantages of the ground, as arising naturally, in point of defence. 2d. The access to, or the possession of, supplies for the army. 3d. The particular object to be attained; whether mere security, the covering of any depot, the cutting off of an enemy's resources, the communication with other parts, and

especially with shipping. 4th. The means of retreat if too closely pressed by a superior force.

The front of an encampment, or, as already explained, of a position, should be intersected by rivers, ravines, or broken grounds, or any other obstacles which may prevent the enemy from advancing in order of battle, and oblige him to pass through defiles: but the front should nevertheless be exempt from such obstacles as might debar the army from moving out of its camp, or advancing when necessary. All obstacles ought to be within reach of the artillery, or the enemy will pass them unmolested. In a flat country, where the ground does not afford commanding situations, a position is more or less eligible according as it may be covered by obstacles; such as very thick woods, in which there are few roads; large rivulets that cannot be crossed but by means of bridges; deep and broken ravines; ground much intersected by ditches and hedges; the possession of mills, churches, convents, and other buildings that are capable of obstinate defence, and are within the encampment. A situation where the rear is covered by swamps has certain advantages, but is attended with this danger, that, in case of defeat, retreat must be difficult, if at all practicable. The principal obstacles, if a choice can be made, ought to be thrown upon the flanks, and force the enemy to narrow his front when attacking the encampment; but, if such obstacles should be of a nature to be easily possessed by him, they will prove peculiarly exceptionable, and ought not to be depended upon, any more than the supply of water from ponds, wells, or streams that lie exposed to his interference. Lastly, the want of wood, or of water, even though provisions should be abundant, totally disqualify a position; unless, indeed, for a very short occupancy, and rather as a resting place than an *appui*, or defensive aid. These deficiencies must invariably operate, on large armies especially, so as to render such situations untenable, whatever advantages they might offer in regard to natural strength, or distress occasioned by their occupancy, to the enemy.

ENCANTHIS, a term in *Surgery*, derived from the Greek *en*, signifying *in*, and *kanthos*, which implies the *angle of the eye*. By a kind of abuse of words, which is too common in every language, the Greek writers have applied the name of "encanthis" to a small, roundish, unequal, more or less considerable, sometimes red, at other times light-coloured tumour, situated in the caruncula lachrymalis, which every surgeon knows is naturally placed near the angle of the eye.

Professor Scarpa, of Pavia, has surpassed every author, with whom we are acquainted, in the excellent and interesting account which he has given of the disease under consideration. To him we feel highly indebted for a great deal of the matter, which we are about to insert. He observes, that the incipient encanthis is a small, soft, reddish, or sometimes slightly livid, excrescence, which grows from the caruncula lachrymalis, and also from the adjacent semi-lunar fold of the tunica conjunctiva. In general, the inveterate encanthis is of very considerable size, its roots reaching beyond the caruncula lachrymalis and semi-lunar fold of the conjunctiva, and extending along the membranous lining of one, or both eye-lids. In consequence of its being situated between the internal commissure of the eye-lids, which it hinders from becoming closed on the side next the nose, it subjects the patient to a great deal of inconvenience, by keeping up a chronic ophthalmia, obstructing the action of the eye-lids, and, in particular, by rendering the patient incapable of shutting his eye. Also, partly by compressing the orifices of the puncta lachrymalia, and partly by altering their natural direction, the encanthis becomes an impediment

## ENCANTHIS.

ment to the free passage of the tears from the eye into the nose.

The encanthis, in its early state, has usually a granulated appearance, like a mulberry; or else it is composed of little portions resembling fringe. When the excrescence has attained a considerable size, a certain part of it has a granulated appearance, while the remainder looks like a smooth, whitish, or ash-coloured substance, streaked with varicose vessels, and sometimes extends so far over the conjunctiva, covering the side of the eye-ball next the nose, that it reaches to the place where the cornea and sclerotica meet. When the encanthis has increased to this considerable pitch, it constantly affects, together with the caruncula lachrymalis and semi-lunar fold of the conjunctiva, the membranous lining of one, or both eye-lids. In this state, it may be observed, that the excrescence, besides the roots, which it derives from the caruncula lachrymalis, and conjunctiva, has a firm prominent appendage, or elongation, which extends along the inner surface of the upper, or lower eye-lid, in the direction of its edge. In other terms, we may state, that the middle portion, or body (as it were) of the encanthis, near the cornea, divides, in the form of a swallow's tail, into two appendages, or elongations, one of which extends along the inside of the upper eye-lid, covered by the edge of this part, while the other is continued along the inner surface of the lower eye-lid, concealed under its margin, and proceeding in the direction from the internal towards the external canthus of the eye.

Scarpa remarks, that the body of the encanthis, or that middle portion of the excrescence, which reaches from the caruncula lachrymalis and semi-lunar fold inclusively, over the conjunctiva of the eye-ball, even to the very edge of the cornea, is sometimes as prominent as a common nut or a chestnut. In other instances, it is of the same size, but depressed and flattened, as it were, in the middle. However, the body of the excrescence does not now retain the same granulated appearance which it presented at an earlier period, while one, or both the appendages, extending along the inner surface of one, or both eye-lids, seem more like a fleshy, than a granulated substance.

When the eye-lids are turned out, these appendages of the encanthis form a projection forward, and when this is observable on both palpebræ, on their being turned out in this manner, the two fleshy appendages make together a kind of ring, which comes into close contact with the globe of the eye behind. Scarpa informs us, that Fabricius Hildanus was acquainted with this disease, which he succeeded in curing, and which he named *ficus scirrhusus ad majorem oculi canthum*. See *Centur. 1. Obs. 2.*

However, Scarpa takes notice, with respect to the case recorded by Hildanus, that the encanthis had only one appendage, which was situated on the inner surface, and below the margin, of the upper eye-lid.

Scarpa, in conformity with most surgical writers, has very accurately explained, that the encanthis, as well as the pterygium, occasionally puts on a cancerous malignity, which is denoted by the dark-red, or leaden colour of the tumour; by its unusual degree of hardness; by its darting pains, which extend to the forehead, and all over the eye and temples, particularly whenever the excrescence has been even gently touched; by its tendency to bleed; and, lastly, by the ulcerations, which occur in several places, emit a fungous growth, and discharge a thin irritating sanies. Scarpa is of opinion, that this worst form of the encanthis can only receive palliative treatment, unless an attempt at extirpation be made, by removing, together with the disease, all the parts contained in the orbit, the success

of which operation he also represents as exceedingly doubtful.

At the same time, that we profess the highest respect for the sentiments of Scarpa in general, on the subject of discharges of the eyes, we cannot silently subscribe to his advice, that no endeavour should be made to effect a radical cure of any malignant encanthis, without extirpating all the contents of the orbit. If the disease were not so very extensive, as to prevent the surgeon from making a fair removal of every part of it, without taking away the eye itself, what practitioner can doubt, that the latter formidable operation ought to be dispensed with. It would be full time enough to have recourse to this severe step, when it had been decidedly evinced, that cutting away the diseased parts alone was insufficient, and that malignant morbid mischief still prevailed.

Scarpa informs us, that the benign encanthis, whether of small, or considerable size, may be cured by excision. The small beginning encanthis, whether of a granulated or fringed appearance, and originating from the caruncula lachrymalis and semi-lunar fold, or, also, from a small portion of the margins of the eye-lids, where they form the internal commissure, may be raised with a pair of forceps, and be completely cut away closely to its base with the curved scissors. In order to accomplish this operation, it is needless to follow the plan, which some adopt, of introducing a needle and thread through the little excrescence, with a view of raising and detaching it more accurately from the parts, to which it is adherent. This object can be fulfilled with the forceps, without annoying the patient by the punctures, and by drawing a thread through the tumour, for the purpose of making a noose. However, in taking away such portion of the incipient encanthis, as arises from the caruncula lachrymalis, Scarpa very prudently cautions us against removing more of the substance of that body, than the complete eradication of the disease requires, lest the loss of too much should occasion an irremediable flux of tears from the eye.

When the little excrescence has been extirpated, the eye ought to be repeatedly washed with cold water to get away the blood, and should then be covered with a piece of fine linen and a retentive bandage. About the fifth, sixth, or seventh day, as soon as the inflammation, produced by the operation, has quite subsided, and suppuration from the wound has commenced, Scarpa advises us to touch the cut surface with a small button of alum, scraped into the shape of a crayon-pencil, and he also recommends a collyrium, containing the zincum vitriolatum and mucilage of quince-seeds, to be frequently applied to the eye in the course of the day. If this plan of treatment should not have the desired effect of making the wound heal; but, on the contrary, if the cut surface of the caruncula lachrymalis and internal angle of the eye should, instead of continuing to heal up, put on a fungous appearance, it should be repeatedly touched with the argentum nitratum, care being taken not to apply this caustic to the conjunctiva, more particularly, if any part of this membrane should have been wounded. After the destruction of the fungous granulations, a collyrium, containing the zincum vitriolatum, will accomplish the cure, or the practitioner may introduce between the eye-ball and internal commissure of the eye-lids, three times a day, an ointment composed of fresh butter, powdered tutty, and armenian bole. Scarpa also acquaints us, that Bidloo speaks much in favour of using for the latter purpose powdered chalk, either alone, or mixed with calcined alum. See *Exercit. Anat. Chir. Decad. 2.*

Scarpa informs us, that we may also cut away the large inveterate

inveterate encanthis, either with a flat body, or with one, which projects in the shape of a common nut, or chestnut, and having one, or two fleshy appendages extending along the lining of one or both the eye-lids. In this instance, a ligature cannot be properly made use of, because the neck of the tumour is never small enough to allow of being advantageously tied. On the contrary, the encanthis, when it is very large, is always extensively connected with the caruncula lachrymalis, and with the conjunctiva, almost as far as where the cornea begins, and it has, moreover, one or two fleshy appendages, which run along the under surface of one or both the eye-lids. For this reason, even should the middle part of the encanthis be extirpated with a ligature, still one or both the appendages would stand in need of removal, which object could only be accomplished by excision.

The apprehension of the bleeding from the latter operation is quite unfounded, as there are numerous cases on record, where the operator has cut away a large inveterate encanthis, without any ill arising from hemorrhage. Scarpa mentions, that he could relate himself some cases which he has met with, in confirmation of the truth of the foregoing statement. This candid writer, however, does not dissimble, that Pellier records an example, in which a troublesome degree of bleeding followed the excision of an encanthis; but, it is justly observed, that the particulars of the disease are undescribed, as well as the exact way in which the operation was performed. Had these circumstances been detailed, perhaps they would have explained the reason of the unusual occurrence. Indeed, Pellier himself has remarked, "j'ai souvent fait cette operation a des excroissances de cette nature, et jamais je n'ai éprouvé un pareil accident."

In the case of the large inveterate encanthis, referred to above, and in which there was only one appendage continued along the inside of the upper eye lid, Hildanus, after taking hold of the body of the encanthis with a tentaculum, drawing the tumour towards him, and turning out the upper eye-lid, in order to make the whole of the appendage project forward, detached all this last portion from the inside of the eyelid with a small knife, and afterwards cut away the body of the encanthis from the conjunctiva and caruncula lachrymalis. Scarpa remarks, that as this plan was attended with complete success, it ought to be imitated by all practitioners.

However, when the inveterate encanthis, of large size, has two apperidges, one reaching along the inner surface of the upper eye-lid, the other along that of the lower one, Scarpa advises the following plan to be adopted. The patient is to be seated in a chair, and the upper eye-lid turned out by an assistant, so as to make one of the apperidges of the encanthis project forward. This production of the disease is to be deeply cut into with a small knife, in the direction of the edge of the eye-lid, taken hold of with a pair of forceps, and be completely detached from the inside of the part, in the longitudinal direction, the dissection being continued from the external towards the internal angle of the eye, as far as the body of the encanthis. The appendage on the inner surface of the lower eye-lid should be separated in the same way. Then the middle portion of the encanthis should be lifted up with a pair of forceps, or, (if this cannot be done) with a double hook, and be entirely cut away from the conjunctiva underneath, which covers the eye ball, and from the semi-lunar fold, and caruncula lachrymalis. This may be accomplished partly by means of a small knife, and partly with the aid of curved scissors. The operator is also to cut more or less deeply into the caruncula lachrymalis, according as the strength and depth

of the roots of the disease may require; for, it must be confessed, that, when the encanthis is very large, and of long standing, the surgeon cannot always avoid wounding the caruncula lachrymalis sufficiently to prevent some degree of weeping from the eye, after the operation.

The eye should be repeatedly bathed with cold water, and the rest of the treatment is nearly like that recommended after removing a small incipient encanthis. Scarpa recommends the use of collyria of aqua malvæ, and of anodyne and detergent ones, until suppuration has fully taken place from the surface of the wound. Then mild astringents, and the above-mentioned ointment may be usefully had recourse to. Scarpa particularly advises giving a preference to mild applications, both before and after suppuration has taken place, especially when a considerable piece of the conjunctiva, covering the white of the eye, has been cut away with the encanthis. See Scarpa Sulle Principali Malattie degli Occhi.

ENCARDION, from καρδια, *heart*, in *Botany*, a name given by the Greeks to what the Latins properly call the mediata in trees, the heart of the wood, or central hard part of it.

ENCATHISMA, from εγκαθισμα, *I sit in*, in the *Medical Writings of the Ancients*, a term used to express a sort of bath, in which the patient was only to be plunged up to the belly.

ENCAUMA, from εν, and καω, *to burn*, in *Surgery*, the mark left by a burn; also a small abscess arising from the same cause. The term is sometimes applied to a superficial ulceration on the eye.

ENCAUSIS, from εν, and καω, *to burn*, a burn, or the inflammation produced by this sort of injury; also the operation of external heat on the body, as of the sun, or fire. In Dr. Cullen's *Nofology*, the word is synonymous with erythema and ambustio.

ENCAUSSE, in *Geography*, a small town of France, in the department of the upper Garonne; 12 miles E. of St. Bertrand, remarkable for its springs of mineral water.

ENCAUSTIC PAINTING, εγκαιστικον, from εν, καω, *inuro*, *I burn in*, is a species of painting with burnt wax, practised by the ancients, and lately revived. Pliny has given the following brief account of the invention and nature of this art: "Cæris pingere ac picturam inurere, quis primus excogitaverit non constat; quidam Aristidis inventum putant, postea consummatum à Praxitele; sed aliquanto vetustiores encausticæ picturæ extitere, ut Polygnoti, & Nicanoris, & Arcefilai, Pariorum Lysippus quoque, Eginæ picturæ suæ inscripsit ενκαυστων; quod profectò non fecisset, nisi encaustica inventa. Pamphilus quoque Appellis præceptor non pinxisset tantùm encaustica, sed etiam docuisse traditur Pausaniam Sycionium, primum in hoc genere nobilem." Lib. xxxv. cap. 11. From this paragraph we learn, that the method of painting in wax, and burning in the picture, was very ancient; nor is it improbable that in former times, when they were unacquainted with dry oils, and transparent varnishes, they should make use of this method for preserving their colours from damps and heats; though some imagine, that by *cæris* is meant a composition, different from wax, and capable of bearing the fire; and that burning the picture denotes merely enamelling. Pliny in the same chapter informs us, that there were anciently two methods of encaustic painting in use: "Encausto pingendi duo fuisse antiquitùs genera constat, cerâ & in ebore, cestro, *i. e.* viriculo: donec classes pingi cæperè. Hoc tertium accessit, resolutis igni ceris, penicillo utendi; quæ pictura in navibus nec sole, nec sale, ventisque corrumpitur." Dr. Parsons maintains, that the *cestrum* was a pointed tool used in modelling

delling or carving upon ivory or wax; and he supposes that there is a contrast between the use of the *castrum*, and painting ships with a brush, and therefore that the term *pingendi* cannot be understood to mean the laying on of paint. However, there is a passage in Vitruvius, lib. vii. cap. 9. which serves to ascertain the nature of the ancient encaustic painting. "At si quis subtilior fuerit, & voluerit expositionem miniaceam suam colorem retinere, &c." *i. e.* if any one is more wary, and would have the polishing, or painting, with vermilion hold its colour, when the wall is painted and dry, let him take Carthaginian wax, melted with a little oil, and rub it on the wall with a hair-pencil; and afterwards let him put live coals into a chafing-dish, and hold it close to the wax; when the wall, by being heated, begins to sweat, let it be made smooth; afterwards let him rub it with wax tapers, and clean linen rags, in the same manner as they do the naked marble statues. This the Greeks call *μαζα*. The coat of Carthaginian wax is so strong, that it neither suffers the moon by night, nor the sun-beams by day, to destroy the colour. From this passage we learn the ancient method of painting in wax by inuision, more obscurely expressed by Pliny; though Pliny, in another passage, expressly informs us, that they used coloured wax: "Cerae (he says) tinguntur iisdem his coloribus, quæ inurantur;" that they employed a pencil to lay on the melted wax; "resolutis igni ceris, penicillo utendi;" that the picture was fixed by inuision, "picturam inurere." And we learn from Vitruvius, that the whole was cleaned and polished with linen rags.

The Punic or Carthaginian wax, the use of which is ascribed to the ancient painters by Varro, Vitruvius, and Pliny, was said to be the best, as it exceeded in whiteness the Sardinian and Corsican, probably because it was better purified; for the Africans, as we learn from Pliny, were accustomed to use alkali in order to render this substance whiter, and also to free it, as some have supposed, from all greasy matter. Wax, however, seems to have formed the only ground of wax-painting. The abbé Requeno, who contributed to present to the notice of modern painters wax-painting, adds mastic; but Lorgna converts his wax into soap, as Bachelier does with the alkali of Soda. Astori adds gum and honey, affirming that thus the wax would be rendered much more yielding and softer for the brush. Requeno seems to assign the exclusive possession of this art to the Greeks and Romans; but we have reason for believing that the knowledge and use of encaustic painting were older than their time, because the Egyptians, who with the Etruscans were the parents of the greater part of the inventions known among mankind, and from whom the Greeks derived much of their knowledge, were acquainted with and employed encaustic painting in the ancient ages of their greatness and splendour. This fact has been deduced from valuable fragments of the bandages and coverings of mummies painted in this manner. A mummy of this kind is mentioned in a treatise entitled "Antichita, &c." referred to at the close of this article. No oil-painting, it is said, perhaps only two or three hundred years old, exhibits a white paint that has kept so well as that seen on the fragment to which we have alluded; and this circumstance sufficiently proves the valuable advantage which that method possesses when compared with the common oil-painting. The wax, instead of becoming black by the contact of the atmosphere, as drying oil does, acquires increasing whiteness, and according to its natural quality, is not decomposed in the air, and does not strongly attract the oxygen of the calces or metallic ashes, which are commonly used in painting. That beautiful white, which may be observed in the Egypt-

ian encaustic above-mentioned, is, as the author of the treatise just cited apprehends, nothing else but a simple earth, and according to his chemical experiments a chalk (*creta*), which is also unalterable. If we consider this encaustic fragment, says our author, as belonging to the epoch of the first violent change, which the religious system of the Egyptians experienced, it will be a specimen of painting about 2500 years old; for such is the number of the years that have elapsed since Cambyzes overturned the ceremonies and religious worship of the Egyptians, not only by the sword, but by the still more powerful weapons of ridicule. Dead bodies were embalmed there in the time of Herodotus, (see EMBALMING); but the cloth in which they were wrapped, or the bandages bound round them, were no longer painted with sacred characters. The bodies were only inclosed in wooden cases, which were more or less ornamented. If Bochart and Ménage be not mistaken, the name "mummiæ" is derived from "muim," which signifies wax; and one might therefore believe, that the dress of embalmed bodies was thus named because wax was employed for painting it; and thence it would follow, that the fragment in question may be classed among the oldest. Petronius praises the fresh appearance which the valuable works of Zeuxis and Apelles had, even in his time; but Cicero, on the other hand, speaks of the paintings of the ancients having suffered from blackness. The former is supposed to have spoken of wax-painting, and the latter is presumed to have alluded to paintings in oil. The author, whose sentiments we are now expressing, detached 24 grains of the encaustic painting from the above-mentioned Egyptian fragment; and in his mode of examining it, the mixture of 100th part of a foreign substance would have been discovered with the greatest certainty: he must, he says, have perceived the resin of Requeno, nor could the alkali of Bachelier and Lorgna have escaped his notice. But in this Egyptian encaustic he found nothing except very pure wax, though he varied his analysis in every known method.

From the words of Vitruvius above cited it appears, that the Romans, who copied the Grecian process, which was borrowed from the Egyptians, mixed the wax with an oil to make it pliable under the brush, but no mastic, alkali, or honey, as some have imagined, was employed; what this oil was it is not easy to ascertain. It does not appear that they used those fat oils, which are commonly called drying oils, because they could have employed those as we do, without the addition of wax, which would have been altogether superfluous. Fat oils, which do not dry, would not have been proper for that purpose, as they would have kept the wax continually in a soft state. Our author supposes, that the Egyptians, in order to use wax in their encaustic painting, must have combined it with an ethereal volatile oil, of which no traces should afterwards remain, and that though they might be unacquainted with the art of separating ethereal oils from the many substances which they contain, they certainly were acquainted with a very volatile thin oil produced by nature, and which in various places issues from the earth. This oil was either that called naphtha, which is an exceedingly volatile oil, that entirely flies off and evaporates, without leaving a single trace behind; or the common spirit of turpentine, which would very well answer the purpose. The encaustum, thus formed, was used in the time of the Romans to cover parts, which had been already painted either with water-colours or in fresco; and it was also, as we have reason to believe, the substance with which Apelles daubed over his paintings, and which, according to Pliny, made them appear as if covered by a thin plate of talc or transparent selenite, and gave the colours a wonderful soft-

## ENCAUSTIC.

ness. It might still be employed for preserving paintings in water-colours, or on plaster, and sculptured pieces of marble.

The ancient art of encaustic painting, after having been long lost, was restored by count Caylus, a member of the Academy of Inscriptions in France; and the method of painting in wax was announced to the Academy of Painting and Belles Lettres, in the year 1753; though M. Bachelier, the author of a treatise "De l'Histoire & du Secret de la Peinture en Cire," had actually painted a picture in wax in 1749; and he was the first who communicated to the public the method of performing the operation of infusion, which is the principal characteristic of the encaustic painting. The count kept his method a secret for some time, contenting himself with exhibiting a picture at the Louvre in 1754, representing the head of Minerva, painted in the manner of the ancients, which excited the curiosity of the public, and was very much admired. In the interval of suspense, several attempts were made to recover the ancient method of painting. The first scheme adopted was that of melting wax and oil of turpentine together, and using this composition as a vehicle for mixing and laying on the colours. But this method did not explain Pliny's meaning, as the wax is not burnt in this way of managing it. In another attempt, which was much more agreeable to the historian's description of encaustic painting, the wax was melted with strong lixivium of salt of tartar, and with this the colours were ground. When the picture was finished, it was gradually presented to the fire, so as to melt the wax; which was thus diffused through all the particles of the colours, so that they were fixed to the ground, and secured from the access of air or moisture. But the method of count Caylus is much more simple: the cloth, or wood which he designed for the basis of his picture, is waxed over, by only rubbing it simply with a piece of bees' wax; the wood, or cloth, stretched on a frame, being held horizontally over, or perpendicularly before a fire, at such a distance, that the wax might gradually melt, whilst it is rubbed on, diffuse itself, penetrate the body, and fill the interstices of the texture of the cloth, which, when cool, is fit to paint upon; but as water-colours, or those that are mixed up with common water, will not adhere to the wax, the whole picture is to be first rubbed over with Spanish chalk or white, and then the colours are applied to it; when the picture is dry, it is put near the fire, whereby the wax melts, and absorbs all the colours.

Mr. J. H. Muntz, in a treatise on this subject, has proposed several improvements in the art of encaustic painting. When the painting is on cloth, he directs it to be prepared by stretching it on a frame, and rubbing one side several times over with a piece of bees'-wax, or virgin's-wax, till it is covered with a coat of wax of considerable thickness. In fine linen, this is the only operation necessary previous to painting; but coarse cloth must be rubbed gently on the unwaxed side with a pumice stone, to take off all those knots, which would prevent the free and accurate working of the pencil. Then the subject is to be painted on the unwaxed side with colours prepared, and tempered with water; and when the picture is finished, it must be brought near the fire, that the wax may melt and fix the colours. This method, however, can only be applied to cloth or paper, through the substance of which the wax may pass; but in wood, stone, metals, or plaster, the former method of count Caylus must be observed.

Mr. Muntz has also discovered a method of forming grounds for painting with crayons, and fixing these, as well as water colours, employed with the pencil. On the

unwaxed side of a linen cloth, stretched and waxed as before, lay an even and thick coat of the colour proper for the ground; having prepared this colour, by mixing some proper pigment with an equal quantity of chalk, and tempering them with water. When the colour is dry, bring the picture to the fire that the wax may melt, pass through the cloth, and fix the ground. An additional quantity of wax may be applied to the back of the picture, if that which was first rubbed on should not be sufficient for the body of colour; but as this must be laid on without heat, the wax should be dissolved in oil of turpentine, and applied with a brush, and the canvas be again exposed to the fire, that the fresh supply of wax may pass through the cloth, and be absorbed by the colour; and thus a firm and good body will be formed for working on with the crayons. If cloth and paper are joined together, the cloth must be first fixed to the straining frame; and then the paper must be passed to it with a composition of paste made with wheaten flour, or starch and water, and about a twelfth part of its weight of common turpentine. The turpentine must be added to the paste when it is almost sufficiently boiled, and the composition well stirred, and left to simmer over the fire for five or six minutes; let wax be dissolved in oil of turpentine to the consistence of a thin paste; and when the cloth and paper are dry, let them be held near a fire; and with a brush lay a coat of the wax and turpentine on both sides the joined cloth and paper, in such a degree of thickness, that both surfaces may shine throughout without any appearance of dull spots. Then expose the cloth to the fire or to the sun; by which means the oil will evaporate, and the wax become solid, and be fit to receive any composition of colour for a ground, which is to be laid on as above directed in the case of cloth without paper.

Almost all the colours that are used in oil-painting may be also applied in the encaustic method. Mr. Muntz objects, indeed, to brown, light pink, and unburnt *terra di Sienna*; because these, on account of their gummy or stony texture, will not admit such a cohesion with the wax as will properly fix them; but other colours, which cannot be admitted in oil-painting, as red-lead, red-orpiment, crystals of verdgris, and red precipitate of mercury, may be used here. The crayons used in encaustic painting are the same with those used in the common way of crayon painting, excepting those that in their compositions are too tenacious; and the method of using them is the same in both cases.

The encaustic painting has many peculiar advantages; though the colours have not the natural varnish or shining which they acquire with oil, they have all the strength of paintings in oil, and all the airiness of water-colours, without partaking of the apparent character or defects of either; they may be looked at in any light and in any situation without any false glare; the colours are firm, and will bear washing; and a picture, after having been smoked, and then exposed to the dew, becomes as clean as if it had been but just painted. It may also be re-touched at pleasure, without any detriment to the colours; for the new colours will unite with the old ones, without spots, as is the case in common size painting; nor is it necessary to rub the places to be re-touched with oil, as in oil pictures; it is not liable to crack, and easily repaired, if it should chance to suffer any injury. The duration of this painting is also a very material advantage; the colours are not liable to fade and change; no damp can affect them, nor any corrosive substance injure them; nor can the colour fall off in shivers from the canvas. However, notwithstanding all these and other advantages enumerated by the abbé Mazeas, and Mr. Muntz, this art has not yet been much practised. Many of these

properties.

properties belong to a much higher species of encaustic painting lately discovered in England, the colours of which are fixed by a very intense heat; nor are the colours, or grounds, on which they are laid, liable to be dissolved or corroded by any chemical menstruum, nor, like the glassy colours of enamel, to run out of the drawing on the fire. See on this subject, Phil. Trans. vol. xlix. art. 100. p. 652. art. 101. p. 655. Id. vol. li. art. 8. p. 40. art. 9. p. 53. Muntz's Encaustic Eloge of Count Caylus, in the Hist. de l'Acad. Roy. des Inscriptions & Belles Lettres, vol. xxxiv. Antichita, Vantaggi e Metodo della Pittura Encaustica; Memoria del Ch. Sig. Gio. Fabbroni, &c. Roma, 1797, 4to. Handmaid to the Arts, &c. vol. i. ch. ix. p. 245. 261.

ENCAUSTICE has been sometimes used to denote the art of *enamelling*, which see.

ENCAUSTUM CERULEUM, is a name given to powder blue.

ENCAUSTUM SACRUM, a name given, by many authors, to that fine red colour used for illuminating the capital letters in some old manuscripts. Procopius calls it *baphe*, some have called it *coccus*, and some *cinabar*. It is said that it was made of the purple colour, extracted from the murex, or purple fish, with some other additions. It is to be observed, that however well this colour, when laid on the parchment, or paper, might resemble the colours of enamel, yet it was as improper to call it encaustum, which signifies a "colour burnt in," as in enamelling it would have been to have called it atramentum, or ink.

ENCEADA DA BELA, in *Geography*, a town of Africa, in the kingdom of Adel, on the coast of the Indian sea; 30 miles S. of cape Guardafu.

ENCEINTE, Fr. from *enceindre*, to surround, in *Fortification*, the wall or rampart which surrounds a place, sometimes composed of battions and curtains either faced or lined with brick or stone, or only made of earth.

The enceinte is sometimes only flanked by round or square towers, which is called a Roman wall.

ENCELIA, in *Botany*, Jusl. 186. Cavanilles Ic. v. t. 44, t. 61, and v. 3. 6. t. 210. see PALLASIA.

ENCEPHALI, in *Medicine*, a term employed by some writers to signify certain worms, said to be generated in the head.

ENCEPHALITES LAPIS, in *Natural History*, the name given, by authors, to a sort of coarse stone, supposed, in some degree, to resemble the human brain. We have, in the fossil world, many stones, named from the parts of animals, which they have, in reality, been formed from, or owed their original to; and these are properly enough called by names denoting the things whose forms they wear; but it is a very wrong practice, from some slight external resemblances, to give such names to things that never can have been supposed to be so entitled to them. No one can be so absurd as to imagine a human brain can be petrified, though a stone may accidentally somewhat resemble its form. The person possessed of such an accidental specimen, should have ranked it among the stones to which it properly belonged as a stone, whether a flint, a pebble, or a nodule, and have named, as an accident only, this form of it; and not have given it a peculiar denomination, as if it were a new species.

ENCEPHALOCELE, from *εγκεφαλος*, the brain, and *κηλη*, a tumour, in *Surgery*, a hernia of the brain. See FUNGUS.

ENCEPHALON, from *εν*, in, and *κεφαλη*, the head, in *Anatomy*, should signify, according to its etymology, all the parts contained in the head; but it is commonly applied to the brain, as consisting of cerebrum, cerebellum, and

medulla oblongata, exclusive of the surrounding and containing membranes. Hence, Soemmerring's *tabula basalis encephali* is a representation of the basis of the brain. See BRAIN.

ENCEPPE, in *Heraldry*, denotes chained, or girt round the middle; as is usual with monkeys, &c.

ENCERIS, in *Pharmacy*, a word used by Galen to signify small concretions of wax, which formed themselves in melted plasters, of which wax was one of the ingredients. As they cooled, the wax cooling first, and collecting itself into little grumes, spoiled the consistence and form of the whole composition.

ENCHANTMENT, of *in*, and *canto*, I sing, denotes certain words and ceremonies used by magicians in the practice of their pretended and deluding art; thus called, because the formulæ of their enchantment were generally composed in verse, and designed to be sung. See CHARM, FASCINATION, MAGIC, SORCERY, and WITCHCRAFT.

ENCHARAXIS from *εν*, and *χαρισσα*, to scarify, in *Surgery*, a scarification.

ENCHASING, or CHASING, the art of enriching and beautifying gold, silver, and other metal-works, by some design or figures represented thereon, in low relieve. See SCULPTURE, RELIEVO, &c.

Chasing is only practised on hollow, thin works; as watch-cases, cane-heads, tweezer-cases, or the like. It is performed by punching or driving out the metal to form the figures from within side, so as to stand out prominent from the plane or surface of the metal.

In order to this, they have a great number of fine steel blocks, or punches, of divers sizes; and the design being drawn on the surface of the metal, they apply the inside upon the heads or tips of these blocks, directly under the lines or parts of the figures. Then, with a fine hammer, striking on the metal sustained by the block, the metal yields, and the block makes an indenture or cavity on the inside; correspondent to which, there is a prominence on the outside, which is to stand for part of the figure.

Thus the workman proceeds to chase and finish all the parts, by successive applications of the block and hammer to the several parts of the design.

And it is surprising, with what beauty and justness, by this simple piece of mechanism, the artists in this kind will represent foliage, grotesques, animals, histories, &c.

ENCHEIREISIS, *Ενχειρησις*, from *εν*, in, and *χειρ*, a hand, in *Anatomy*, denotes manual operation; as dissection.

ENCHELIS, in *Zoology*, a genus of *Vermes Infusoria*, described essentially as being invisible to the naked eye, very simple, and cylindrical. Nearly all the species are found in stagnant water.

#### Species.

PYRUM. Inversely conic, behind transparent. Müll.

Common in stagnant waters, where the duck-weed grows. Body obtuse, and filled with molecules; and when at rest, appears to have a small tubercle in the middle of the body. This kind is remarkable for the rapidity of its motion.

SPATHULA. Cylindrical, striated, with a transparent spatulate tip. Müll.

Less frequent than the last, and found in waters in which the duck-weed is infused. The body is crystalline, and the creature moves in an undulate manner.

PAPULA. Cylindrical, with the tip papillary. Müll.

Found in the water of dunghills. The body is round, protuberant, opaque before, and furnished with a papillary finger-shaped head; pellucid behind, and both ends obtuse. Its motion is rotatory and oblique.

**FRITILLUS.** Cylindrical, truncated anteriorly. Müll. Hermann.

Met with in water in which grafs or hay is infufed. The body is pellucid, convex, and obtufe behind; moves backwards and forwards with a wafing agitation in a line.

**OVULUM.** Cylindrical-ovate, and hyaline. Müll.

Found in the water of dunghills. Very minute and pellucid.

**FUSUS.** Cylindrical, narrow, and truncated at both ends. Müll.

Observed only in pure water.

**EPISTOMIUM.** Elongated, cylindrical, with a fender fub-globular tip. Müll.

Inhabits putrid water. The body is round, obtufe behind, and its fize minute.

**SEMINULUM.** Cylindrical and equal. Müll.

In water kept fome days. The body twice the length of its breadth, pellucid before, and opaque behind. Moves by alternately afcending and defcending.

**NEBULOSA.** Oval-cylindrical, with vifible moveable intefines. Müll.

Found in waters with cyclidium glaucoma.

**FARCIMEN.** Cylindrical, curved, and truncated at both ends. Joblot.

In water kept a few days. Body opaque, and in its motion often appears in the fhape of the letter S.

**VIRIDIS.** Green, fub-cylindrical, and obliquely truncated before.

Abundant in water kept fome weeks. Tail obtufe, intefines obfcure.

**ENCHELUS,** *Εγκελος*, in *Ichthyology*, the name given by Aristotle, Appian, and all the Greek writers, to the eel.

**ENCHESON,** a French word ufed in our *Law-Books* and *Statutes*, fignifying the occafion, caufe, or reafon, wherefore any thing is done. Stat. 5 Edw. III. cap. 3.

**ENCHRISTA,** from *εγκρινω*, to *anoint*, in *Surgery*, liniments with which parts are anointed.

**ENCHYMA,** of *εγχυω*, *I pour in*, in the *Medical Writings of the Ancients*, a word ufed in feveral fenfes. Some have made it exprefs only an *infufion*; others have ufed it for what the modern phyficians call *plethora ad vafa*, that is, a fulnefs of the veffels, fimplly confidered, as a relative to themfelves; and others have made it the name of certain forms of liquid medicines, to be injected into the ears, into the thorax, or any other part.

**ENCHYMOMA,** of *εγχυμοσ*, from *εγχυω*, in the *Writings of the Ancient Phyficians*, a word ufed to exprefs that fudden effufion of blood into the cutaneous veffels, which arifes from joy, anger, fhame, or any other violent emotion of the mind, and is what we ufually call blufhing; which, according to Dr. Hunter, is a nervous affection.

**ENCHYMOMA** is alfo an afflux of the blood, whereby the external parts are rendered black and blue, as in the fcurvy, blood-hot eyes, &c.

**ENCHYMONITES,** in *Natural Hiftory*, the name of a kind of ftone found in Macedonia, and fome other places, which was alfo called *peonites* and *peanites*: it was fuppofed to be of great virtue to affift women in labour. See **CEANIDES**.

**ENCHYMO'SIS,** from *εγχυω*, to *pour into*, in *Surgery*, an extravafation of blood from the veffels, attended with black, blue, or livid appearance of the part. See **ECCHYMOSIS**.

**ENCHYSMA,** the fame with clyfter or enema.

**ENCHYTA,** in the *Medical Writings of the Ancients*,

a name given to fuch medicines as were injected into the eyes, or into any part.

Some alfo have ufed the fame word to exprefs a fort of funnel, contrived to convey the fumes of medicines to any part of the body.

**ENCKENDORP,** in *Geography*, a town of Germany, in the duchy of Holftain; 6 miles S.E. of Rendsburg.

**ENCKHUYSEN,** or **ENCKHUIZEN**, a confiderable town of Holland, on the Zuyder Zee, in North Holland; 9 miles N.E. of Horn, and 30 miles N.E. of Amfterdam. N. lat. 52° 40'. Its commerce, and particularly its herring-fifhery, was of great importance in former times; but its harbour is now almoft entirely choaked up with fand.

**ENCLAVE'**, in *Heraldry*, is where one thing is let into another, particularly where the jointure is fquare.

**ENCLITICA,** of *εγκλιτω*, *I incline*, in the *Greek and Latin Grammar*, certain particles, united fo clofely to the preceding word, that they only feem to form one word therewith; and the word which fufstains them does generally likewife bear the accent that governs them, efpecially when the enclitic is a monofyllable; as in *deminusque*, *κλιτω*; *τε*.

There are three enclitic particles in the Latin, *viz.* *que*, *ne*, and *ve*; but in the Greek many, as *τε*, *με*, *μοι*, *μι*, *σε*, *σοι*, *σν*, *πω*, *σπ*, *τε*, *γε*, *φημι*, *εμι*, *ποτι*, and others.

**ENCLOS, L'**, in *Biography*, a mufician in Louis XIII.th's band, an eminent performer on the lute and theorbo, or fingle and double lute.

He was father of the celebrated Ninon, who played on thefe inftruments as well as himfelf.

He dying in 1630, left her an orphan at 15 years old, beautiful, full of wit and talents, and formed to infpire the moft violent paffion. Nor did fhe wrap her talents in a napkin, but availed herfelf of all their influence; and even at more than fourfcore, fhe is faid to have awakened love in the learned abbé Gédoin.

It is pretended that cardinal Richelieu had her firft favours, and that he was the only one to whom fhe furrendered, without confulting her inclinations.

She was then 17, and it is certain that, ever after that time, fhe received a penfion of 2000 livres annually, which was long regularly paid.

Ninon gave concerts at her houfe, where perfons of the firft rank and talents came to admire her performance on the lute and harpfichord. The philofopher, Huyghens, the famous aftronomer, likewife obferved Ninon with great attention and accuracy, and even wrote verfes on her, which Voltaire calls *Geometric*.

“ She has inftruments five, which my brain much difturb,  
The two firft are her hands, the next are her eyes;  
But my tongue for the fifth and the beft I muft curb,  
Nor its beauties attempt to difclofe, if I'm wife.”

She was feldom left by her lovers, but fhe left them very foon; yet fhe always retained a friendship for her old admirers.

She was fo celebrated, that Chriftina queen of Sweden made her a vifit in 1654, in a fmall villa which fhe had in the neighbourhood of Paris.

Madame de Maintenon was her beft friend; and Voltaire afferts that M. de Villarecau was a lover in common with both, without its occafioning a quarrel.

He had two children by Ninon. The hiftory of the eldeft is known, who at 19 years old became paffionately enamoured of her; but on making the difcovery, he blew his brains out. Her fecond fon, called Boiffiere, died at

Rochelle in 1723, commissary of marine. She loved seriously for some time the marquis de Sévigné, brother of madame de Grignan; but who never wrote the letters to her, which M. d'Amouré has printed under her name about 40 years ago.

Madame de Maintenon, becoming all powerful, remembered her, and lent her word that she would take care of her fortune, if she would change her way of living, and think seriously of religion: Ninon replied, that she neither wanted fortune nor a mask. Ninon died at Paris, 1705, at the great age of 90.

ENCÆLIA, of *εν, in,* and *κοιλια, belly,* a word used by many of the ancient medical writers, to express the viscera contained in the abdomen, or lower belly.

ENCOLPIUM, or ENCOLPION, the pectoral cross of bishops, abbots, abesses, &c.; being one of the ordinary marks of the dignity of such persons both in the Latin and the Greek church.

ENCONDROS, of *εν, in,* and *χονδρος, grain,* in the *Old Greek Writers,* a word used to express any thing made up of a great number of small pieces, or flakes, or small grains of any thing. The manna of the ancients was not in large flakes, as we have it at present, but it was formed of a vast number of small granules, and was therefore called by Dioscorides, and some others of the Greeks, by this name. The word manna also signified with them the same thing; and they not only expressed the substance by it which we at present call so, but any other thing that was in small flakes, or pieces, was called manna. Thus the manna thuris, so much talked of among the old Greeks, was only a collection of those pieces which flew off from frankincense in the breaking. See MANNA *Libanotis.*

ENCOPE, of *εν,* and *κοπιω, I cut,* in *Surgery,* an incision of any part; as in a gangrene, &c.

ENCOUNTER, in a *Military Sense,* relates to that kind of deliberate attack, which is totally abstracted from accidental hostility, and may therefore be considered in contradistinction to the rencontre, which ordinarily implies a fortuitous meeting. Thus we find, "to lead troops to the encounter," is a very common expression; though we occasionally hear the term misapplied by persons who describe the losses, &c. sustained in accidental warfare, as having taken place, not in the rencontre, but in the encounter. We should also understand, that, in the strict sense, (which relates entirely to the arranging of troops opposite, that is, *en-contra,* to the enemy,) we ought not to consider circuitous attacks, and those feints made merely for the purpose of distracting the enemy's attention, as coming under this definition; and, on the other hand, we consider not only those who come into actual engagement, perhaps to the point of the bayonet, as is often the case in the attacks made by columns of infantry, but the supporting divisions also, to be engaged in the actual encounter. Thus we frequently perceive, that the leading regiment of a column is engaged, while the rear regiments bear no share in the contest; but if their situations be such as to expose them to the enemy's fire, they must be as much considered in the encounter as a vessel coming to the aid of another, so as to cause the enemy's ship to surrender, or to retreat. Hence it has ever been held a rule, that all vessels in fight, when a capture is made, become entitled to shares in the prize; because, on many occasions, the approach of reinforcements adds to the vigour of one party, while it depresses the spirits of the other, and influences it to decline further contest.

ENCRANIUM, in *Anatomy,* the same with cerebellum.

ENCRAVICOLUS, in *Ichthyology,* a species of clupea. See CLUPEA and ANCHOVY.

ENCRATITÆ, formed from *εγκρατις, continent,* in *Ecclesiastical History,* a sect of ancient heretics, thus called from their making profession of continence, and absolutely rejecting all use of marriage.

The founder of this sect was Tatian, a disciple of Justin, and one of the most learned persons of all antiquity. After the death of that martyr, he made a separation from the church, and soon had his followers; who, beside the dogma just mentioned, borrowed a great many things from Saturninius and Marcion; beside several errors, which they adhered to in common with the Gnostics and Valentinians.

They abstained from eating any thing that had life, and denied that Adam was saved. They looked on such as drank wine to be great sinners; and for this reason only made use of water in celebrating the Eucharist, as holding, that wine came from the devil. To countenance this tenet, they produced passages out of scripture, where mention is made of what befel Noah and Lot, when they were drunk.

They only admitted such of the books of the Old Testament as they thought good; but in lieu thereof, they owned several spurious and apocryphal writings for canonical and divine. Such were the Acts of St. Andrew, John, and Thomas.

ENCRAULOS, in *Ichthyology,* the name given by Aristotle, and many other of the ancient Greeks, to the fish which we call the anchovy. See CLUPEA and ANCHOVY.

ENCRINITES, in *Natural History,* a kind of columnar extraneous or organized fossil, found in the earth. See ENCRINUS, PENTACRINI, and ENTROCHI.

ENCRINUS FOSSIL, is the remains of an animal, so called by some; by others, this class of zoophytic remains is called *encrinites* (Parkinson's *Organic Remains,* vol. ii. p. 153.); and by others, denominated *entrochi,* or *pentacrini.* See those articles. See also Harenberg's *Encrinus* S. Liliun Lap. 4to.

ENCRINUS, a species of *Pennatula,* in the class of zoophyte worms, comprehending the cluster-polypi of Ellis, and inhabiting the Greenland sea.—Also, the name given by Ellis to the Ateria, a species of Isis, inhabiting the ocean that washes the coast of Barbadoes.

ENCRIS, in the *Medical Writings of the Ancients,* signifies a sort of cake made of fine flour, mixed with oil, and sweetened with honey.

ENCROACHMENT *of the Sea,* in *Geography,* signifies the sudden or gradual conversion of dry land into the verge of the ocean. History records numerous instances of great and devastating effects of this kind: some occasioned by the waves of the sea undermining the cliffs on its shore, and carrying away the matter thereof as fast as they fall, by which the boundaries of the sea have been considerably enlarged in some places; and its ravages still continue with increasing effect in some places, as on the chalky shores of Kent and Suffex. Another kind of marine encroachment, highly interesting to the geologist, is evidently taking place, by slow degrees, on a considerable portion of the flat shores of England; and can only be explained by an exceeding slow and gradual subsidence of the island itself, or a corresponding rise of the ocean which bounds it. This is particularly visible in the fens and marshes of our coast, which

which are now defended by banks of that magnitude and height, which scarcely any effort of the present day could at once effect; but which, as in the marshes embanked from the Thames below London, must have been begun centuries ago, when the tide flowed not so high by many feet as it does at present, and have been gradually raised, as the height of the water increased. The finding of immense fallen woods of trees, of the recent species, with the marks of human labour on them, and even the very tools by which they were felled, under great thickness of peat, the whole of which is now much below the level to which the tide rises twice each day, are also proofs of this general encroachment of the sea; since neither peat nor trees of any kind will grow where the salt-water of the ocean even saturates, much less continually overflows the ground. The mention of various instances of ancient and high embankments of marshes and fens against the tide, will be found under our article CANAL, in the divisions *Thames, Ouse, Welland, &c.* See also EMBANKMENT.

ENCROACHMENT. See INCROACHMENT, and AC-CROCHING.

ENCURECK, in *Natural History*, a venomous insect, found in Persia, and supposed by some to be a kind of tarantula. It neither stings nor bites, but lets fall its venom like a drop of water, which causes insufferable pain in the part for a time; and afterwards so profound a sleep, that we are told nothing can raise the patient from it but crushing one of those creatures on the part affected. It is nevertheless said, that the sheep eat these insects without damage. Olearius, ap. Boyle, Works abr. vol. i. p. 37. Ibid. p. 38.

ENCYCLOPÆDIA, the circle or chain of arts and sciences.

The word is compounded of the preposition *εν, in*, *κυκλος, circle*, and *παιδεια, science, doctrine, discipline, learning*; the root being *παις, child, infant*.

The Greeks used the term for the knowledge of the seven liberal arts, and the possession of all the sciences. *Orbis ille doctrinae, quem Græci εγκυκλοπαιδειαν vocant*, says Quintilian. It is sometimes also written *κυκλοπαιδεια, cyclopaedia*. Vitruvius, in the preface to his sixth book, calls it *encycliis disciplina*. See CYCLOPÆDIA.

ENCYSTED TUMOURS, in *Surgery*, swellings, which are formed of a bag, or cyst, which is filled with matter very various in its consistence and appearance. When the contents of the cyst resemble pap, the tumour is named *atheroma*; when they are of the consistence of honey and wax, it is called *meliceris*; when they are fatty, it is termed *steatoma*. See these words, and especially TUMOURS.

END for END, in the *Sea-Language*. When a rope runs all out of the block, so that it is unreeved, they say it is run out end for end.

The same phrase is applied to a cable that has wholly run out of the ship. In general, it denotes the reversal of the position of any object.

END-on is applied to a ship, which advances to a shore, rock, &c. without any apparent possibility of preventing her.

ENDE, in *Geography*, one of the smaller Molucca islands, S. lat. 8° 30'. E. long. 120°.

ENDEAVOUR RIVER, a river on the N. E. coast of New Holland, which at its mouth has a small bar harbour, or creek, that runs in a winding channel three or four leagues inland, and having at its head a small brook of fresh water. There is not depth of water for shipping above a mile within the bar. This part of the coast is fo

barricaded with shoals, as to make the harbour difficult of access, the safest approach to it being from the southward. S. lat 15° 26'. E. long. 215°.

ENDEAVOUR Straits, a channel or passage, so called by Cook, between New Guinea and New Holland, the N.E. entrance of which lies in S. lat. 10° 39'. W. long. 218° 36'. It is formed by the main, or the northern extremity of New Holland, on the S.E., and by a congeries of islands, which Cook called "the Prince of Wales's islands" to the N.W., which islands probably extend quite to New Guinea. The length of this channel from N.E. to S.W. is ten leagues, and it is about five leagues broad, except at the N.E. entrance, where it is somewhat less than two miles, being contracted by the islands which lie there. The depth of water in the strait is from four to nine fathom, with every where good anchorage, except upon the bank, which lies two leagues to the northward of Wallis's islands, where, at low water, the depth is only three fathom.

ENDECAGON, or HENDECAGON, in *Geometry*. See HENDECAGON.

ENDECASYLLABUS, or HENDECASYLLABUS. See HENDECASYLLABUS.

ENDECANDRIA, in *Botany*, from *ενδεκα, eleven*, and *ανηρ, a man*, an order of the Linnæan class *Monadelpbia*, characterized by having eleven stamens, whose filaments are, as the character of the class itself requires, united into a tube. It contains only the genus *Brounea*, the number of whose stamens is different in different species, and this precise number of eleven is so unusual, and apparently unnatural, in flowers where five and ten so much predominate, that perhaps the order in question might be, without mischief, abolished.

ENDECERES, of *ενδεκα, eleven*, in the *Naval Architecture of the Ancients*, a word used to express a galley which had eleven series or tires of rowers. Those with two or three tires were very much in use among the ancients, and from those to such as had five or six tires. Those of nine tires were sometimes used, but it was very seldom; and those of eleven, fifteen, and so on, were rather for state, than service. We read of them carried so high as to contain twenty, thirty, and forty rows of oars. One of this largest sort was built for Philopater, which required four thousand men.

ENDEIXIS, *Ενδειξις*, in *Antiquity*, an action brought against such as affected any place or thing, of which they were incapable by law. Pott. Archæol. Græc. lib. i. cap. 23. tom. i. p. 125.

ENDELAVE, in *Geography*, a small island of Denmark; eight miles N. of Funen.

ENDEMIC, or ENDEMIAL, *Diseases*, from *εν, in*, and *δημος, a nation, or people*, are those diseases which occur among the inhabitants of a particular region or place, in consequence of certain circumstances belonging to it, and not arising from contagion, or any other general cause.

Thus agues, or intermittent and remittent fevers, which are occasioned by the miasms of marshy ground, are endemic in low countries: the *goitre*, or bronchocele, connected with that peculiar intellectual imbecility, which characterizes the CRETIN, is endemic among the Alps, where its origin has been erroneously ascribed to the use of snow-water: the colic, *COLICA Pisonum*, is endemic in the cyder-counties, especially in Devonshire: the bilious remittent fever, or yellow fever, is endemic in the West India islands; and so forth. In all these instances, some local cause obviously exists, which produces the disease in the respective districts, the disease belongs to the districts, therefore, and affects those who reside there, but extends no farther. Whereas

an epidemic disease is produced, or at least propagated among the people, in consequence of some general cause; as contagion, famine, or, perhaps, some change in the condition of the atmosphere at large.

Hence the distinction between endemic and epidemic diseases is obviously of great importance, for, in both cases, much more beneficial purposes may be accomplished in the way of prevention, than in that of cure. But the prevention of diseases depends altogether upon a knowledge of their causes, which should therefore be accurately investigated, whenever they prevail extensively. If a disease is endemic, *i. e.* originates in some local cause, (from marsh effluvia, for instance;) it may attack the same person again and again, while he remains in the same situation; but he infallibly escapes it by removing his residence; or the inhabitants of the district may be all defended from its attacks by draining the marshy ground, whence the miasmata issue. Thus we are told by writers on the diseases of armies, that the disorders which arise from the foul ground of camps, are readily made to disappear by removing but a few hundred yards from the situation which they previously occupied. And of the beneficial effects of attention to the local causes of endemic diseases, we have a striking example in the changes, which have occurred in London, in respect to the diseases of its inhabitants. In the time of Sydenham and Morton, *viz.* in the latter half of the seventeenth century, remittent and intermittent fevers were generally prevalent to a great extent, in the autumnal season, and were often extremely fatal to the inhabitants of the metropolis; and the bills of mortality shew, that formerly the dysentery, which almost constantly appears in the same places and seasons as the remittent fever, was annually fatal to great numbers. But of late years these diseases have almost entirely disappeared; intermittents occurring only occasionally after wet seasons, in those people who have visited the fenny counties during the harvest; and dysentery sometimes prevailing, in a mild way, in those seasons only when the heat has been unusually great. This exemption, which London now enjoys from those endemic diseases, is chiefly to be ascribed to the improvements that have been made in the pavement, drains, and sewers, and the attention that is paid to cleaning and supplying with water the several parts of the town. In some towns where these precautions are neglected, the remittent fever is still found at times to commit great ravages. It is probable that the fever, which proved so fatal in Philadelphia, in the year 1793, was of this kind, and produced from the causes just mentioned. (See Rush's Observations on the Fever of Philad. 1799. Dr. Miller's Report, New York, 1806.)

Some writers confine the term *endemic* to those diseases which are constantly present in certain districts, at all times and seasons, such as the *goutre* of the Alps; and call those *epidemic*, which are the product of certain seasons, although originating in a local cause, as the autumnal intermittent and remittent fevers of fenny and hot countries. See EPIDEMIC.

ENDENA, in *Geography*, a town of Italy, in the Bergamasco; seven miles N. of Bergamo.

ENDEDENTED, DENTED, or *Indented*, in *Heraldry*. See INDENTED.

ENDEDENTED is also applied to a fess or pale, and other triangular pieces, when divided alternately between two different colours. Coupé, or endedent with or and azure.

ENDER, in *Geography*, a town of Italy, in the Bergamasco; 12 miles N.E. of Bergamo.—Also, a river of Scotland, which runs into the Garry, seven miles W. of Blair Athol, in Perthshire.

ENDERSTORF, a town of Silesia, in the principality

of Neysze; 3½ miles, S. of Ziegenhals.—Also, a town in the same country and principality; 3½ miles S.W. of Grotkau.

ENDESIS, from *en* and *des*, *I lind*, a word used by Hippocrates to express that part of the foot where the bones of the tibia end, and which is connected by ligaments to the ankle.

ENDEW, in *Falconry*, is said of a hawk that digests her meat so well, that she not only discharges her gorge of it, but even cleanses her pannel.

ENDIAN, in *Geography*, a town of Persia in the province of Chusistan; 150 miles S.S.E. of Susa.

ENDICA, a word used by the alchemists for the fæces which subside to the bottom of the vessels in infusions: to some of which they attribute great virtues.

END-JOINTS, in *Mining*, otherwise called *cutters*, in coal-mining, are the shorter of the natural joints or upright partings of any measure or stratum; the longer of these joints being called *Backs*, *Slines*, face or lengthway-joints, or partings: for it seldom happens in any quarry or work, that the face-joints are not much longer than the end or cross-joints.

ENDINGEN, in *Geography*, a town of Germany, in Austrian Swabia; seven miles N.W. of Fribourg.

ENDINGS OF STRATA, in *Geology*, signify the edges of the strata, in their greatest advance towards the north west, or in the direction of their general *rise*, according to the observations of Mr. William Smith and his followers; by whom it has been observed, in all the eastern parts of England, that the strata *end* successively towards the N.W. generally with a fingered or digitated outline, in some, in places running out for miles in ridges, beyond the general range of the edge or limit of the stratum: the more recent observations in Derbyshire, at Chelmsleton-low, for instance, and other projecting points of strata in that *denudated* district, shew, however, the necessity of a careful attention to the fingered or projecting points of strata, and to other concurrent circumstances, before such fingerings alone are admitted as proofs of the ending of a stratum, rather than as part of the edge of a denudated tract, on the opposite side of which the same stratum is to be found again, either on the surface, or abruptly sunk beneath it by a fault, and upper measures occupy that surface. See DENUDATION, and CONCENTRICITY of Strata.

ENDITEMENT, or INDICTMENT, in *Common Law*. See INDICTMENT.

ENDIVE, in *Gardening*, the common name of an esculent plant which is well known in garden culture. There are different varieties of it, but that which is perfectly curled, is the most useful for culinary purposes. See CICHORIUM.

ENDIVIA, in *Botany*, *Cichorium Endivia* of Linnæus, the garden endive. Ambrosini derives the word from *edendo*, eating, because the plant is so grateful to the palate. It appears to us rather a corruption of one of its old names *Entyba*, or *Intuba*.

ENDIVIA MARINA, the *sea-endive*, in *Natural History*, the name of a species of sea plant, or marine substance, described by count Marsigli. There are two species of it, the one having broad and jagged leaves, resembling those of the vine, the other much narrower. This last kind grows on stones, shells, pieces of wood, or any other substances, accidentally found at the bottom of the sea. It seldom grows in very deep water, and thrives best in places where the sea is calm and quiet. It is of a dusky greenish colour, variegated in some places with yellow. It exactly resembles the shape of the endive common in our gardens, and its leaves are cut and fringed in the same manner; but

but they are of so tender a substance, that a slight touch destroys them; they are indeed tenderer and more delicate than those of any other known plant, either of the sea or land. When this substance is examined by the microscope, its surface is found to be composed of a great number of eminences and cavities, or little holes, between and among them; and when the leaves are cut transversely, there are seen a great number of glandules in them. Marfigli, *Hist. de la Mer*, p. 72. See CORALLINES.

ENDLESS ROLLS, and *Sereze*. See the Substantives.

ENDOCARPON, in *Botany*, from *ενδοσ*, *within*, and *καρπος*, *fruit*, alluding to the receptacle of the seeds being deeply imbedded in the substance of the leaf, or rather frond. Hedw. *Crypt. v. 2. 56. t. 20. f. A. Ach. Prod. 140. Meth. 125.* (Lichen; Zoega Island. 15. Dicks. *Crypt. fasc. 2. 22. With. v. 4. 52. Sm. Engl. Bot. v. 9. 595, &c.*) Class and order, *Cryptogamia Algæ. Nat. Ord. Lichenes.*

Gen. Ch. Frond cartilaginous, rigid, rounded, peltate, depressed; naked beneath. Receptacles immersed in the substance of the frond, globose; their edges a little protuberant; their concave disk lodging the seeds in vertical cells, and at length expanded and displayed.

Ess. Ch. Receptacles immersed, globose, concave, in which the seeds are imbedded.

This genus is, perhaps, more judiciously than most separated from the great genus or family of *Lichen*, by Hedwig, followed by the accurate Dr. Acharius. The only question is whether *Verrucaria* ought not to be joined with it, as differing not at all in the parts of fructification, though its frond is a crust instead of a leaf, just as his various *Parmelia* differ, even more widely, among themselves. Several species of *Endocarpion* are figured in *Engl. Bot. t. 593—595. 1512. 1698. 1866. 2012, and 2013.* They are small roundish or angular plants, commonly growing closely pressed to the earth or stone, of a grey or olive hue, their fructification appearing like little black dots over the surface.

ENDOR, in *Ancient Geography*, a town of Judea, in the half-tribe of Manasseh, on this side Jordan, according to the book of Joshua. Eusebius places it four miles S. from mount Tabor, near Naim, in the way to Scythopolis.

ENDOR, *Witch of*. See WITCH of Endor.

ENDORSE, in *Heraldry*, an ordinary, containing the eighth part of a pale.

This, Leigh says, is never used but when a pale is between two fuch: though others hold, that an endorse may be borne between birds, fishes, beasts, &c. Sir J. Ferne adds, that it shews the same coat has been sometimes two coats, and afterwards conjoined within one escutcheon, for some mystery of arms. He bears azure an endorse argent.

ENDORSED, ENDOSSE', is where things are borne back to back.

ENDORSEMENT, of *in* and *dorsum*, *back*, is particularly used, in *Commerce*, for a writing on the back of a bill of exchange by the proprietor or bearer, either thereby to transfer it to some other, or to render it payable to the order of some other, or else to serve for an acquittance or receipt. See EXCHANGE.

The endorsement is only the name of the proprietor, or endorser. Note, when the endorsement of a bill of exchange is to render it payable to another, it is called an *order*.

To an order it is necessary the endorsement be dated; and contain the name of him who paid the value thereof; in which case, the bill belongs to the person with whose

name the order is filed, without any other tradition: without these conditions, the bill is judged to belong to the person who endorsed it. The bearer of a bill of exchange protested has a remedy against the endorsers for the payment of the re-change of the places where the bill was negotiated by their order. In case a bill or note is refused to be paid, &c. the bearer has a remedy against any one of the endorsers, where there are several. See BILL.

ENDORRING, or INDORSING, in *Law*, implies the writing on the back side of a deed, instrument, &c. something relating to the matters contained therein.

ENDOSIS, *Endosis*, of *εν* and *διδωμι*, *I give*, in the *Medical Writings of the Ancients*, a word used to express a remission of any kind, as when a tumour, inflammation, or hardness of any part, becomes less violent; and when the patient becomes easier, after the exacerbations in fevers of the continual kind, and after fits of the intermittent.

ENDOWMENT, or INDOWMENT, the giving or assigning of a dower to a woman. See DOWER.

The word is also used figuratively, for the setting forth or serving a sufficient portion for a vicar, towards his perpetual maintenance, when the benefice is appropriated; whence such a vicarage is called a vicarage endowed.

ENDRACHIUM, in *Botany*, *Juss. 133*, see THOUINIA. The name is barbarous, corrupted from the Madagascar word *Endrach*, under which it occurs in *Lamarck's Encycl. v. 2. 356*, who nevertheless calls the genus *Humbertia*, following *Commerçon*. See *Lamarck's plates, t. 103*. Dr. Smith named it *Thouinia*, and is followed by *Schreber, Willdenow, and Martyn*.

ENDRAPA, in *Ancient Geography*, a town of Asia, in Mesopotamia, situated on the left bank of the Euphrates.

ENDSCHUTZ, in *Geography*, a town of Germany, in the circle of Upper Saxony, and circle of Neustadt; 4 miles E.N.E. of Weyda.

ENDYMATIA, in *Antiquity*, a kind of dance used among the Greeks, performed in Arcadia, to the sound of certain airs composed for the flute.

ENEDA, in *Geography*, a town of Switzerland; in the canton of Glaris; 2 miles E. of Glaris.

ENELIAXIS, *Ενελιαξίς*, or rather *Enyalixis*, *Ενυαλιξις*, in *Antiquity*, a festival in honour of Enyalus, whom some will have to be the same with Mars, others only one of his ministers. *Pott. Archæol. Græc. lib. ii. cap. 20. tom. i. p. 394.*

ENEMA, of *ενεμα*, *I put in*, in *Medicine*, denotes a clyster. See CLYSTER.

ENEMY. See ALIEN.

ENEOREMA, of *εναιρω*, *I lift up*, is used by ancient medical writers for those parts of the urine which float about in the middle resembling a cloud, formed, according to Boerhaave, principally of muriatic salt. *Comm. Initit. § 382.*

ENEOS, of *εν* and *ωσς*, *I cry*, a word used by the ancient writers in *Medicine*, for a person born deaf, or unable to perform the common offices of life, for want of any of the principal organs.

ENERGETICAL BODIES or *Particles*, are such as are eminently active, and which produce manifest operations of various natures, according to the various circumstances and motions of such bodies or particles.

ENERGICI, in *Ecclésiastical History*, an appellation given to certain disciples of Calvin and Melancthon, of the sixteenth century, because they held the Eucharist was the energy and virtue of Jesus Christ; not his real body, nor a representation thereof.

ENERGUMENUS, *Ενεργουμενος*, a term sometimes used

by divines and schoolmen, to signify a person possessed with a devil, or an evil spirit.

The word is formed from the Greek, *εργασιας*, to be agitated, worked, of *ερ*, and *εργον*, *opus*.

Though Papias says, the Energumeni were such as counterfeited the actions of the devil, performing things which seemed supernatural. The council of Orange debars, or deprives the Energumeni of the functions of the priesthood. See DEMONIAC.

ENERGY, in *Elocution*, a mode of delivery applicable to particular passages of a discourse that are meant to be rendered particularly impressive and operative upon the feelings and convictions; like emotion, if not too frequently appealed to, or too extravagantly exerted, it has a great tendency to demonstrate the sincerity and real earnestness of the speaker; which is always one of the indispensable requisites for the conviction of the hearer. In declamation it should be manifested alike in the enunciation, the tones of the voice (which should be firm and fervid), and in the gesticulation. It is this quality in the speaker that seems to have been designated by Demosthenes as the first, second, and third requisite of an orator. *Actio* (*Ενεργεια*, the Latin *actio*;) not being confined in signification to the mere motion of the limbs, but to the entire and reciprocal exertion of the mental and organic faculties of the speaker, the co-operative energy of thought, language, enunciation, tone, look, gesture, and deportment. "Et actio oratoris pronuntiatio ac gestus, & ipsa adeo administratio causæ." Cic. in Orat. c. 17. "Oratorical action is pronuntiatio and gesture; hence the very delivery of the subject." "Est actio quasi corporis quædam eloquentia, cum constet e voce et motu." Quintil. Q. 3. "Action is, as it were, a certain eloquence of the body, consisting in voice and motion." See also Gesner's *Thesaurus* in voc. *actio*.

ENERGY, in *Painting* or *Sculpture*, may be divided into two parts, *viz.* energy of thought, and energy of execution.

The former consists in deeply investigating the nature and interest of a subject, and selecting that most impressive and decisive moment for representation (and also the mode of doing it) which shall convey to the imagination of the beholder with the greatest interest, either its history or its moral.

The latter consists in that same active, animated spirit, being accompanied by the power of displaying the representation of that selection, either on marble or on canvas, with force, with freedom, and precision; without labouring, at least without leaving the appearance of labour, in endeavouring to obtain its expression.

The comparison of two artists who in their works have each respectively exhibited the possession of these two qualities in the highest degree, will best illustrate our meaning.

Raphael's works are full of energy of thought. Those of Titoretto of energy of execution.

The former always fixes upon that precise moment of time in a story which is most favourable for relating it with success; and is sure to interest by the force and truth with which he unfolds the circumstances of it. He sometimes even, and that with the greatest propriety, goes farther than the mere relation of the particular subject; he accompanies and illustrates it by allusions to antecedent and subsequent events connected with it; as in the cartoon of the death of Ananias.

In that picture, some of the disciples on the right of St. Peter are still engaged in distributing alms, not yet having observed the instantaneous punishment inflicted by Almighty vengeance on the guilty sinner; we are thus unaffectedly

informed of the object for which the apostles are assembled, and how they were engaged previously to the time of the immediate subject of the work, and we are led as simply to understand somewhat of that which followed, by the introduction of the figure of Sapphira; who advances on the opposite side, intent upon counting the money she may be supposed proposing either to give to the fund devoted to charity, or to withhold, that she might gratify her own, and her now dying husband's avarice; whose fate, of which she appears to be altogether unapprized, so nearly awaited herself, for her design of committing the crime for which he was so awfully punished.

Thus we see, that no part of the interest of the subject escaped the active energy of the mind of Raphael, and many others of his works would as well illustrate his great ability in this point of the art; *e. g.* the cartoon of St. Paul preaching at Athens, but in neither of these noble works is there much energy of execution: that was the forte of Tintoretto.

He seldom stopped to think correctly and refinedly upon his subject. He rarely portrays the passions with truth in the countenances of his figures, or gives his story interest on the mind; except by the astonishing freedom, force, and fire of his pencil in the execution, where it appears to have moved with the utmost rapidity; the canvas trembles under it. His vigour in colour equals the skill of his workmanship; and these united, the observer forgets the want of more valuable beauties. The skill of the matter strikes more than the work itself. His execution well deserves the appellation bestowed upon it by the Carracci, "Il terribile maniera del Tintoretto." It still remains a desideratum in art to see it united with elegance of design; with feeling, and truth in thought, and expression.

In sculpture the author of the Laocoon has effected their union. We may, therefore, hope its sister art may sometime arrive at an equal degree of perfection. But there are so many more points of difficulty to overcome in painting than in sculpture, that he must be almost super-human who effects it.

Many will rather wish that Michael Angelo had been instanced as possessing energy of thought in preference to Raphael; and justly he might have been hailed as a wonderful model of it, as he also was to a considerable degree in the other acceptation of the word, *viz.* in execution. But his energy is less understood than that of Raphael; and is of a less valuable kind; as it not infrequently renders his figures enigmatic, and nature is lost in art. Raphael comes equally with him, home to his subject; and can scarcely ever be misunderstood. Hence, therefore, we think ourselves justified in presenting the latter to the attention of our readers rather than the former; not as willing to depreciate Michael Angelo; but because we conceive, that while the consideration of his energetic powers may invigorate the student, it may divert his mind from truth, and lead him to bombast and affectation; which the contemplation of the works of Raphael never can do, unless he be of a most perverse stamp of nature indeed. If energy of thought may be said to be characterized by those strong workings of the imagination alone, which produce the representation of the most extraordinary and powerful actions of the human body, with bold fore-shortenings and strong expressions; then M. Angelo claims by far the highest place, but we do not conceive that to be the best criterion for judgment on this point. He who sees clearest, and while he gives it powerfully, most justly and beautifully illustrates his subject, must surely have as fully and warmly conceived the nature of it; as he, who, mixing the extravagance of enthusiasm with his energies, permits his mind to run wild upon it; and throws upon his

canvas figures which rather confuse than exemplify, and draw the attention of the observer from the subject to the painter. This enthusiasm, we think, does characterize in a great measure the wonderful works of M. Angelo; whilst Raphael's mind, though full of energy, is pure, and going to the extreme of indulgence in his subject, still keeps within its bounds.

**ENERVATING**, the act of destroying the force, use, or office of the nerves, either by cutting them, by weakening them with debauchery, or by some other violence.

Excess of wine, and other strong, hot, spirituous liquors, enervate or weaken the nerves. When they would render a horse useless, they enervate him, or cut his nerves.

**ENERVATING**, is particularly used in the *Manege*, for the cutting two tendons on the side of a horse's head, under the eyes, which meet on the tip of the nose; they thus enervate horses, to make their heads small and lean.

The word is also used figuratively. It is no small artifice in disputing, to be able to enervate and extenuate the allegations of one's antagonist. This author has a weak enervate style. See **NERVE**.

**ENERVATION**, a term in the *Ancient Anatomy*, applied to the tendons of the recti, or straight muscles of the abdomen.

The fibres of the recti of the abdomen do not go from one extreme of the muscles to the other, but are intersected by several nervous places, called by the ancients enervations, though they be real tendons.

Their number is not alike in all; some having three, others four, &c.

**NERVE, FOLIUM**, in *Botany*, a leaf destitute of ribs and nerves. See **LEAF**, and **COSTATUM FOLIUM**.

**ENFANS PERDUS**, a French phrase, used in war to signify the soldiers who march at the head of a body of forces appointed to sustain them, in order to begin an attack; make an assault, or force a post.

The word literally imports *lost children*, on account of the imminent danger they are exposed to.

In English, they are called the *forlorn*, or *forlorn hope*.

At present, the grenadiers usually begin such attacks.

**ENFIELD, WILLIAM**, in *Biography*, was born at Sudbury in the year 1741, and educated for the ministry among the Protestant dissenters at the academy at Daventry, where he distinguished himself by the polish of his early compositions. He was first settled as minister with the congregation at Benn's garden, Liverpool; this was in the year 1763; and, in 1770, he became resident tutor and lecturer in the belles-lettres in the academy at Warrington. He shortly after qualified himself as mathematical tutor, and in that character published "The Institutes of Natural Philosophy," in quarto. A new edition of this work was published after the doctor's death, with considerable additions, and an introduction to the modern doctrines and discoveries in chemistry. It may be reckoned one of the best popular introductions to Natural and Experimental philosophy. During his labours at Warrington, which were highly prized, the university of Edinburgh conferred upon him the title of doctor of laws. In the year 1785, he removed to Norwich, and became pastor of the congregation of dissenters in that place. With the duties of this office, he successfully employed himself in various literary undertakings, among which was the laborious task of translating and abridging "Brucker's History of Philosophy," a work to which we have frequent occasion to refer in the course of our own investigations of the learning of ancient times. This abridgment was published in two vols. 4to. in 1791,

and "probably," says his friend and biographer, Dr. Aikin, "the tenets of the different sects of philosophers were never before displayed with so much elegance and perspicuity. It was, indeed, his peculiar talent to express the ideas of other men to the greatest advantage. His language, chaste, clear, correct, and free from all affectation, is one of the best specimens of that middle style which is fitted for all topics, and he communicates to his reader all that clearness of idea which reigned in his own mind. These qualities, together with the candour and moderation which made part of his very constitution, especially fitted him for the office of literary criticism, and he was long an associate in one of the most respectable of the periodical journals." He died November 3d, 1797, in the 57th year of his age, generally beloved and lamented. In every relation of life, the benevolence of a kind heart displayed itself in the most engaging features. He published "Sermons," "Family Prayers," and "The Preacher's Directory." His compilations, entitled "The Speaker," and "Exercises in Elocution," are perhaps the most popular works in our language, and they unquestionably merit the patronage which they have had, and continue to have. After his death three volumes of his sermons were published by subscription, and the numerous friends who patronized this work, will prove the attachment which he had inspired. Gen. Biog.

**ENFIELD**, in *Geography*, a town and parish in the hundred of Edmonton, and county of Middlesex, England, is situated nine miles from London, and contained, according to the late return to parliament, 926 houses, inhabited by 5881 persons.

It is styled in ancient records Ensen, or Insen, from its fenny soil, which is now, however, converted into good land, by draining, &c. The parish is very extensive, the town itself being but a small part of what bears the name of Enfield. The parish church is an ancient structure, and has been recently repaired. Here are a good free school, and two meeting-houses for dissenters. Part of an ancient royal palace still remains, where Edward VI. is said to have resided, and where queen Elizabeth kept her court in the early part of her reign. One of the rooms appears in its original state, with oak panels, and a richly ornamented ceiling: the chimney-piece is of admirable workmanship, and decorated with the arms of England and France quartered. The palace was alienated from the crown by Charles I. and has ever since been private property. In 1670 it was taken by Mr. Uvedale, master of the grammar-school, who, being attached to botanical studies, planted in the garden a cedar of Libanus, which, in 1793, measured twelve feet in girth, three from the ground. The town had formerly a good market, which is fallen into disuse. In the suburbs are a number of boarding-schools, and several elegant villas. Enfield was heretofore much celebrated for its *Chase*, which comprized a large tract of woodland, well stocked with deer; but during the civil war it was stripped both of game and timber, and let out into small farms: after the restoration it was again laid open, woods planted, and filled with deer. In 1779 it was disafforested by act of parliament; parcels were allotted to different parishes, and the remainder sold. A part was bought by Dr. Jebb, who having successfully attended the duke of Gloucester at Trent, the king, on conferring the dignity of baronet on him, gave the name of Trent-place to the villa which he had erected here. South Lodge, also on the chase, was the favourite retirement of the late earl of Chatham. East Lodge was the hunting seat of Charles I.

In this parish, at a place called "Four-tree hill," or Forty-hill, the late Richard Gough, esq. had a seat, where

where he died; in February 1809. Some account of this eminent topographer and antiquary will be given in a subsequent part of this work. Lyson's Environs of London, vol. ii.

ENFIELD, a township of America, in Hartford county, Connecticut, on the east bank of Connecticut river, opposite to Suffield, and bounded on the north by the Massachusetts line; settled in 1681. In 1769 it contained 214 English families. In the town are two congregational churches, and a meeting-house for the sect called Shakers. The town is pleasant, and contains 1761 inhabitants; 18 miles N. of Hartford.—Also, a township in Grafton county, New Hampshire, about 11 miles S.E. of Dartmouth college; incorporated in 1761, and containing 1121 inhabitants.

ENFILADE, a French term, sometimes used in English, signifying a series or continuation of several things, disposed, as it were, in the same thread or line; as an enfilade of rooms, of doors, of buildings, &c.

The word is formed of the French verb, *enfiler*, to string a thing, which is compounded of *en*, *in*, and *fil*, of *filum*, thread; *q. d.* a thread or string of any thing.

ENFILADE, in *Military Matters*, relates to a certain mode of acting upon the defenders of lines, redoubts, batteries, &c. thereby counteracting the impediments thrown in the way of a direct fire. To explain this, it is necessary to observe, that defences may be attacked in three modes; *viz.* *direct*, that is, by a responsive fire in front, or, at least, so little obliqued as to come under the general acceptance of what the French engineers term *siyant*, or, plunging; this fire is commonly at right angles with the line of defence to be battered: when the fire is much obliqued, it is said to be *razant*, or grazing. The second mode of attack is by *reverse*; that is, where the batteries of the besiegers can be so directed as to command the interior of the rampart, and thus render it impossible for the defenders to remain at their guns. This mode generally relates to an angle of at least fifteen degrees from the line of the defence in question, but may extend to any angle up to 90°; remarking, however, that the more direct the fire may be in reverse, the less execution will be done, because the shot can only strike one particular object. The third mode is by *enfilade*, and is always the most destructive, especially if the guns of the enfilading battery can be brought to bear at a right angle with the direction of the battery to be enfiladed. When this cannot be effected, it is necessary to make a small angle in reverse, the less the better, thereby to throw the shots along the interior of the parapets, and to take the whole in flank. Some fortresses are unavoidably so situated as to have one, or perhaps two batteries exposed to a very distant enfilade. Such a defect is of the utmost importance, and cannot be radically overcome; for we sometimes see some hill, or what is worse, some shifting sand, which cannot possibly be either removed or occupied, but which affords both a command, and a lodgment in security from the fire of the place. Although this is assuredly an immense drawback on the strength of the works, it is nevertheless in some situations of little moment; for instance, where it is necessary to retain a small force for the purpose only of preventing an enemy from landing at the only accessible spot upon a long range of coast, presenting in every other part such natural obstacles as annihilate all apprehensions of invasion. In such place the surrounding eminences are of no moment; or if they were, must rather be considered as offering advantages, and the means of rendering the place untenable to the enemy, should they succeed in carrying the works.

Speaking generally, however, a fortress that can be en-

filaded with tolerable safety to the besiegers must be untenable; because it is impossible to devise effectual means for remedying the evil. It is true, we may raise large epaulements, or batteries of soil, masonry, &c. for the purpose of preventing the enemy's shot from ranging along the rampart; but, in most instances, where enfilades can be made, these epaulements would require to be carried to such an immense height, as must, in a measure, deteriorate the other defences; in some instances rendering them nugatory, or even advantageous to the assailants, whenever they may be able to make a lodgment. Besides, such epaulements are very liable to be destroyed by mortar and howitzer batteries, or by mines. This mode of parrying the enfilade has, with much propriety, been of late years designated by the French engineers a *defilade*, a term peculiarly expressive of the intention of whatever devices may be used for the purpose of preventing defences from being enfiladed. It must not be forgot, that the approaches of besiegers should be carefully constructed; else they may be subjected to enfilade from some of the defences. That evils, however, easily avoided; and if, through ignorance or inadvertence, found to take place, may be instantly corrected, as the besiegers have, on almost all occasions, ample range for alteration, and can adopt a variety of measures totally unattainable to those within the fortrefs.

Where a work is carried over a rising ground, it is generally very difficult to render the interior of the batteries safe from either reverse or enfilade. The best mode is to carry them up the ascent *en escalier*, that is, by short levels, each perhaps capable of mounting four or five guns, and every such level being cut off from its neighbour below, by a heavy epaulement, carried up high enough to prevent the besiegers from trundling their shots along within the parapet. The most effectual method of cutting off enfilades is to give the rampart such an augmentation of thickness as may allow a free passage for cannon, &c. along the rear of those in the embrasures, and to fill up the spaces between the latter with *traverfes*, carried to at least ten feet in height. These traverfes are nothing more than regular masses of soil, properly turfed, or perhaps reveted with masonry, placed at right angles with the parapet, and uniting therewith: their thickness ought not to be less than ten feet.

We must here observe, that with few exceptions, the enfilade commonly takes place from the exterior flank of the battery; therefore that quarter should be chiefly attended to. With this view it is found most proper to construct each traverse partly of masonry, and partly of soil well gazoned, (*i. e.* turfed) or, if on emergency, firmly retained by fascines. Sometimes sand bags will be found to answer for this part, when the residue of the thickness is completed with good masonry, at least four feet in substance. Where cotton, or wool, or raw hides, are procurable, they will be found to make admirable traverfes, if sustained by a firm wall: these being placed nearest to the enfilading quarter, will, by their elasticity, completely deaden the force of the shot, however great their calibres, and cause them, if they should reach so far, to be weak and insignificant in their impression upon the interior buttress of masonry. It should seem, to persons unacquainted with the practice of defending places, that, in consequence of the great resistance offered by solid masonry to cannon-shot, which will often bury themselves full fifteen feet, or more, in ordinary soil, the traverfes should be constructed of masonry only: this would, no doubt, present great firmness in a contracted space; but the inconceivable destruction and dismay occasioned by the splinters knocked off by shots that strike upon bricks or stones, opposes an insuperable bar to what would otherwise prove a

most valuable mode of construction; such, indeed, as would render many places absolutely impregnable. This compels us to resort to such materials as are, in a great measure, devoid of such mischiefs, of which turf is the best.

It is generally considered, that the enfilade is cut off by placing traverses at from fifteen to twenty toises asunder; but the latter distance, (equal to forty yards,) is certainly too great: it would even be advisable to bed the guns between traverses, as we have above shewn, were it not that by so doing the battery must be weakened, owing to the spaces occupied by so many buttresses. However, necessity and, generally speaking, locality, must give laws for the construction of such impediments to the enfilades. It must be understood, that the obnoxious battery may be very powerful; that is, it may not only mount heavy cannon, but may be far more numerous than might at first be supposed. To explain this, it must be stated that the most destructive enfilade is that which ranges along the interior of a battery, at about from two to six feet within the parapet; since in that direction it is sure to destroy not only the defenders, but even the cannon, dismounting them, and crushing the gunners, as well as causing a variety of splinters to scatter among them, from the several parts of the wood and iron work. Sometimes, indeed, when the shots touch upon the cannons themselves, the former, being of cast iron, and consequently liable to shiver when forcibly struck, break into numerous pieces, or even fracture the latter, so as to render them perfectly unserviceable.

If shots were to be fired at such an elevation as barely to graze the crest, or summit, of the parapet, they would certainly prove most destructive to the defence flanked by such a forcible fire; but this cannot be effected at short distances, since, it is evident, the shots would, at the moment of touching the crest of the parapet, be *ascending*, and that too with such force as could not fail to impel them far over every part of the fortrefs, and thus to prove completely unavailing. This mode of enfilade, therefore, commonly takes place where the cannon is not at least on a level with the crest of the parapet, so as to send its shot through it with sufficient force to cut clean through, without being thrown upwards into a new direction, and thus to plunge into the more remote part of the defence. When the enfilade is more distantly situated, the shots may certainly be thrown over the parapet as they are *descending* upon their long range; but this is very uncertain, and rarely does much execution; to be sure, when the shots can be correctly thrown, the havoc they create is dreadful.

The usual mode of enfilading is by ricochet, that is, by giving the piece, whether mortar, howitzer, or cannon, such an elevation, and such a charge, as may cause the shot to bound first on the glacis, and then over the rampart into the battery. This, our readers will perceive, is exactly on the principle of "a three-quarter ball" at cricket; which, if it passes over the wicket, makes several low bounds, or, as they are technically termed, "lobs," in proceeding along their course, until they come to a state of rest. So does a cannon-shot, after bounding over a rampart, keep lobbing, rather more forcibly indeed than a cricket-ball, along the terre pleine of the rampart. It will not be necessary to expatiate on the effects of this dreadful contrivance, they being so obvious, and so completely similar to what is called "raking fore and aft," in naval warfare.

The most powerful ricochet takes place at an angle under ten degrees of elevation; fifteen degrees are the utmost that are allowed, both because the effect produced is less when the elevation is encreased, and the gun-carriage is proportionally injured by the direction of the recoil deviating from

the horizontal, so as to depress and strain the hinder parts of the frame work; while, at the same time, the wheels are lifted in the fore part, and return to the ground with undue force. When mortars are used in ricochet firing, they are commonly charged with a number of shots, or of shells, forming in the whole, what we may term, a round of grape proportioned to the calibre of the piece. In batteries intended solely for ricochet firing, the embrasures should have their superior slope outwards, as seen at K in the plate; whereby the enemy could not fire into it so easily as if the embrasures were made in the usual way: in fact, they could not distinguish them, as the whole would be nearly solid, much the same as a mortar-battery. Where infantry or cavalry are to be fired at in ricochet, the pieces must not be elevated more than three degrees, otherwise their greatest effect would not be produced. Ships may likewise be acted upon by ricochet, if the shots are caused to strike the water at a *depressed* (instead of an *elevated*) angle of about four degrees, so as to touch the surface at from two hundred to two hundred and fifty yards from the battery. But this applies only to particular cases; for if the vessel be remote, or that any object is to be fired over, the same angle of elevation may be used, taking care so to proportion the charge, that the shot may light upon the water at about two hundred yards from the vessel, if she be large; but if small, the shot must light nearer to her, in proportion to her want of bulk.

It was necessary to say thus much of ricochet firing, in order to give a complete insight into the manner of enfilading by means of small charges of powder. The reader will likewise perceive that several guns may enfilade the same battery, in exactly the same line, merely by causing them to be removed farther from the object of attack, the one behind the other, only taking care that the parapet before each be sufficiently substantial to prevent accident to the other batteries in its front, and causing the more remote to charge higher, in order that their shot may be thrown sufficiently far to make the first bound in a proper manner, over the epaulement of the defence to be enfiladed. We should observe that the mode of enfilading before-mentioned, namely, by grazing directly over the crest of the parapet, may be extended to remote works; but unless they are manned for action little damage will be done, as the besieged will rarely fail to *house* their cannon, by pointing them towards the enfilading-battery; so that they may be far less exposed than when standing in their proper directions.

We shall annex to this article, which we have dwelt upon in deference to its importance in military affairs, a few general principles. 1st. That the descending enfilade is the most destructive in long ranges. 2dly. That the ricochet-enfilade is peculiarly adapted to short distances. 3dly. That the angle should, if practicable, be kept under ten degrees of elevation; the greater effect being generally in proportion to the less deviation from the horizontal direction. 4thly. That the more direct the fire may be along the line, or defence, to be enfiladed, the greater will be the damage done thereto, provided it be within such a parallel with the parapet as may subject both the cannon and the gunners to its range. 5thly. That if any angle is to be made with the line to be enfiladed, a few degrees in reverse are better than even half their number in advance; because, though the former may not strike any object in its original course, the shots may, after having grazed against the interior of the parapet, *genouillere*, &c. still do considerable damage; and, even though they should not either dismount a cannon, or kill any of the men on the battery, they must tear the garon-revetement far more than one of masonry, which is often put exteriorly, though not within: the latter would turn the shots

off, in all probability, and cause them to have only the effect of a weak fire *razant*. 6thly. It will be necessary to ascertain the thickness of the parapet behind which the enfilading shots are to trundle: in common fortifications it may suffice to compute, as nearly as may be practicable, upon about four toises, (or eight yards,) from the extremity of the superior slope of the angle; but in places where the parapets are made of masonry, less will commonly be necessary, for the purpose of striking somewhere upon the line of platforms, and of thereby dismounting the cannon. 7thly. Where howitzers are used for the enfilade, the traverses must be very numerous, to prevent the pieces of bursten shells from spreading to any extent. But, in such case, the traverses will not require so much solidity, as if opposed to heavy shots. 8thly. Where a remote battery is to be enfiladed, especially if the enfilade be direct, that is, in a line with the prolongation of such battery, great care must be taken to be exact in ascertaining its distance from that part of the defences which may be nearest to the enfilading party. This may, in general, be done, with precision, by means of two long ladders placed face to face, and elevated during the night, so as to give a command of the works then in a state of actual opposition; when the flashes from their cannon will prove a sufficient guide. This may, however, be done with more precision during the day time, though certainly with more danger; but the operation being certain and speedy, compensates for the risk. The enfilade on such occasion must not be by ricochet, but by descent. Those who are in front of the enfiladed battery, or nearly so, will see the effects of the shots, and can, by means of pre-concerted signals, give information accordingly to the enfiladers.

The following references to the figures in *Plate III. Fortification, fig. 1*, will explain more fully what has been said.

Let *AB* be the face of a bastion, whose salient or flanked angle, *B*, is battered in breach from *CC*. In such case, the besieged must make a very strong epaulement from *B* to *P*, on the adjoining face, to prevent the shots from the enfilading battery at *D* trundling upon the terre-pleine of the face *AB*; in aid of this resistance, the traverses, *S, S, S*, must likewise be thrown up. The battery at *D* being a direct enfilade, that is, in the line of the face *AB*, is highly destructive; while that at *E*, which is only  $15^\circ$  in reverse, is far less so. It is indeed evident, that one cannon at *D* would be more effectual than two at *E*; unless the shots from the latter should be thrown in so as to fall upon the nearest part of the interior of the parapet, as has been already implied: they would then be capable of tearing away the interior of the merlons, and of causing great numbers of splinters, &c. The battery at *F* is a direct-enfilade of the face of the remote bastion *H*; but its fire must not be in ricochet, (as that could never reach its object,) but by descent. At *I*, an enfilading battery is shewn in profile, the cannon being sunk, and the embrasure, *K*, having an inverted slope, covering the cannon from the fire of the battery at *L*. This slope being only  $10^\circ$ , admits the shots from the cannon to ascend, by means of a small charge, in a curve meeting the ground at *N*; thence reascending over the face *L*. (corresponding with *BP* in the upper figure,) so as to light again at *O*, upon the terre-pleins of the face *M*, (here seen in reverse, and corresponding with the interior of *AB* in the upper-figure;) whence it will again rise, and, if unimpeded, bound on in successively diminishing curves, until its force be expended. The dotted line, from the cannon *I* to *O*, on the bastion *M*, shews the direct or plunging-enfilade by descent, which is best adapted to cannon of a smaller calibre; the force of the shot being, in

this instance, unabated by any bound; as must be the case in ricochet, wherein, by striking at *N*, the impetus is considerably diminished. This diminution will be greater, in proportion as the elevation of the cannon is increased. As already stated, the enfilade of *H* from *F* will be of little moment, unless the battery at *H* be in action; but, as the obliquity of the embrasures may enable the enfiladers at *F* to act either in ricochet, or by descent into the reverse of *AC*, or even of *AB*, there might be considerable advantage gained by such a position. It is proper to state, that this does not appear to be generally practicable; as the distance from *C, C*, (the main breaching-batteries,) to *F* must render the latter rather insecure, and expose it both to the batteries of the place, and to the fallies of the garrison: it is therefore given merely as an illustration of the terms used in the explanation of all that relates to enfilade. When shipping, or craft of any description, lie behind a mole, so as to be secure from the direct fire of any battery, the ricochet-enfilade may be adopted, either by elevation, as shewn above; or by depression, as from the cannon at *P* directed downwards to *Q*; whence the shots will bound over the mole *R*, and fall among the vessels behind it. This is occasionally done to destroy vessels in a harbour, or to enfilade such as may be actively employed in any attack; and thus to force them to a change of position, rather than suffer themselves to be raked fore and aft with hot balls.

**ENFILED**, in *Heraldry*, is applied to a sword, on which is placed the head of a man or beast, or any other charge.

**ENFRANCHISEMENT**, the incorporating any man into a society or body politic. See **FREEDOM** and **FRANCHISE**.

Thus, he that by charter is made denizen of England, is said to be enfranchised. The like is understood of a person made a citizen of London, or other city or corporate town; because he is thereby made partaker of the liberties appertaining to the corporation whereof he is enfranchised.

**ENFRAPPANT**, *Fr.*, in *Music*, a term applied, in beating time, to the first note of a bar.

**ENGADINE**, in *Geography*, one of the highest vallies of Switzerland, in the canton of the Grisons. It is divided into the Upper and Lower Engadine. St. Martin's bridge on the river Inn separates the Lower Engadine from the Tyrol. The towns of this valley are less agreeable than those of the upper one; but the soil is uncommonly productive. In some places the roads are narrow and rocky, and nature displays its wildest scenes. The river Inn is often compressed in a narrow deep channel: there are, however, a few fine plains, where fruits come sooner to maturity than in the Upper Engadine, from which it is divided by the Pont-Alta. The situation of the upper valley is much higher; it has very long winters, and the air is generally cold. In the midst of summer, night frosts nip the corn and fruits. The towns are agreeably situated, and mostly handsome, built of free-stone, and painted white; even the barns are fine buildings. The river Inn flows slowly in a larger bed; there are several beautiful bridges of a single arch thrown over it. Near the pretty town of Schoulz are fourteen springs of mineral water of different qualities. There are several manufactures, chiefly iron works and founderies, in the Engadine, which give employment to a great number of its inhabitants, and an appearance of cheerfulness and comfort to their habitations.

**ENGAGE**, *To*, when applied to *Military* or *Naval Affairs*, means to attack. Perhaps no circumstance incident to warfare requires more precaution, or indeed more judgment,

judgment, than that relating to the giving battle to an enemy. The general, or commander of any description, who neglects to provide against those checks which arise, often when least expected, or for following up any advantage he may gain, especially if it be within the limits of his anticipations, must be totally unqualified for so responsible and so important a situation. We speak principally of proceedings in the field, where many alterations and much diversity may be perpetually offering; for we consider the manner in which battles on the ocean generally proceed, and in which they almost invariably terminate, to be so pre-eminent as to leave us only the opportunity of describing them, (as we shall do under the head of *ENGAGEMENT*;) and to debar us, unless indeed we wished to incur the charge of presumption, from stating when or how single ships or fleets should engage the enemy.

In the first instance, it will be absolutely necessary for the commander of an army to know, with precision, the states of health, of discipline, of fatigue, of supply, and of competency in general, of every corps composing his army. He must be thoroughly informed as to the condition and numbers of his cattle, of the amount of his provisions, and of the manner in which the several corps, the cattle, and the supplies, are distributed along his line. He must have a thorough knowledge of the numbers, the disposition, the supplies, and the probable resources, of the forces opposed to him; as well as of the nature of their warfare, their general habits, the strong posts in their rear, the opportunities they may have of forming ambuscades, or of retreating to advantage; and especially whether, in case of success, he may be able to avail himself of those invaluable opportunities which the valour and discipline of his troops may offer to his acceptance.

However confident a general may be of success, he must never lose sight of the possibility of a reverse: in truth, it is most generally found, that where the best preparations are made against disaster, the most decided victories are obtained. This is natural, both because the whole of a line feel inspired by the reflection, that due provision is made for the worst; and because, where such arrangements are carefully preconcerted, the appropriate remedy is prompt for application, and the enemy are rendered unable to continue in that line of successes, which, but for such apt opposition to their momentary or local advantages, must inevitably be at their command.

Whenever we observe that a commander courts the opinions of those whose rank and experience may qualify them to offer advice, we may consider it a most fortunate omen. The immortal Nelson always disclosed his plans, and opened his mind fully, to the admirals and captains under his command: he solicited the correction of whatever errors might have crept into his projects, and was eagerly anxious that all should have a competent understanding of his intentions. This ought ever to be the study of a commander; else, should he fall, or should unforeseen accidents occur in any part of his line, his successor, as well as his subordinates, must be totally at a loss either to continue victorious, or to arrest the progress of the enemy.

But perhaps the most essential point may be for a commander to ascertain how far his troops are well disposed to the cause; whether they proceed to engage with alacrity and zeal; and whether they have an entire confidence in the courage and abilities of their leaders. This part of the subject is sometimes overlooked, until it is too late to be remedied; and the moment of engaging is the moment of treason, or of cowardice. It is true, the British army may claim an exemption from these ungovernable mischiefs; but

no commander should be indifferent to matters which are within the scope of possibility, and which may often be avoided by a little courtesy, or by some well directed policy. We should consider, that in our time the most unforeseen events are daily brought forth; that the opinions of persons inimical to the welfare of the state are every day promulgated; and that, within these very few years, even a field officer of our army endeavoured to mislead those guards, who are exclusively appointed to protect his majesty's sacred and most valuable life. Fortunately for Britain,

“ Such divinity doth hedge our king,  
That Treason dared but peep at what it would !”

Therefore we may ever hope that the disposition of our soldiery will remain unshaken; and that we may find them, as they ever have been, bold, active, and obedient in the field, and ready on all occasions to engage in support of our king, and our constitution.

It may be proper to add, that too much ardour to engage may exist in an army: this is assuredly dangerous. There is a certain established coolness in veteran regiments, resulting from the presence of perhaps only a small portion of veterans among them, which is highly conducive to the character and to the prowess of the corps at large. Such regiments are admirably calculated for resistance; while new levies are generally more suited to the charge, and to those tremendous conflicts which speedily terminate the struggle in their quarter. In truth, we are well assured from the most respectable authorities, as well as from the numerous facts which proudly and pre-eminently offer themselves to our notice, that nothing can resist the attack of our new regiments; while, on the other hand, nothing can subdue the firmness and patience of our old ones.

*ENGAGEMENT*, in the *Military Profession*, relates to such conflicts as take place between bodies of armed men, generally regular troops, and especially to that kind of warfare which is carried on between armies of some magnitude, in contradistinction to those less extensive contests, which ordinarily are considered as skirmishes. Engagements may be either partial or general; in the latter case, they are commonly attended with marked and decided consequences; whereas, in the former instance, little or no difference may be made in the positions of the contending powers. We generally find, that, according to the modern mode of warfare, great ingenuity and cunning are exerted, for the purpose of deceiving the adversary into an opinion of a general attack. This is done with the intention of preventing reinforcements being sent from any part, the whole being kept in action, while the main attack is made on some point, either naturally weak, or by gaining which the fortune of the day may be determined in favour of the assailants. This, although it bears the appearance of a general engagement, is in fact but a partial assault; the greater portion of the contest falling upon a few regiments, which, unless properly supported, are commonly swept away: to say the least, they must suffer very considerably.

Previous to engaging the enemy, every attention must be paid to securing a retreat, in case of a check. This precaution is indispensable in all ordinary instances; though, in some situations, it may be found the best policy to destroy the means of evasion, under the intention of convincing the army that it has only the alternatives of victory or death. Thus, when Cæsar landed in Britain, he destroyed the fleet which had brought him to our shores; a measure which, in those times, compelled the invaders to fight to the last. They knew they had to contend with an enemy, from whom

## ENGAGEMENT.

whom no quarter was to be expected; therefore, like rebels, they struggled for life; they fought virtually with halters around their necks; and, thus rendered desperate, contended with such savage, such unrelenting fury, as necessarily caused the engagement to be sanguinary to an extreme.

Engagements are of two kinds; namely, either in the field, where the opposing parties are both divested of the protection of fortifications of any description, such as we ordinarily find to take place in open countries; the other consisting of that mixed kind of warfare, which comprises the attack and defence of *abbaties*, the crossing of rivers in the face of an enemy, and, on many occasions, the attacks made upon open towns, &c. With respect to those engagements which are connected with the forming of lines, or of fortifications of any description, we consider such to appertain to that protracted system included under the head of *siege*, which see; and the attacks upon such to be, not engagements, but assaults.

It is scarcely to be credited upon what very slight incidents the fate of an engagement may depend! Circumstances, which, if considered in the cabinet, should appear to be akin to impossibility, arise unexpectedly, and change the face of affairs instantaneously. Hence, during the moment of contest, a commander should be intent on obviating those mischiefs which must result from the falling back, or the failure, of any part of his army. He must carry in mind, and perhaps might advantageously delineate on a card, the great outline of the engagement; studying to choose such a position as may give him a general view of the field, but most especially of such portions as may either appear to him either weak, *ab origine*, or to be hard pressed by the enemy.

To describe an engagement is next to impossible; for though we might perhaps afford some general idea of the incidents usually occurring during a battle, such is the diversity to be found in the localities, as well as in the systems of warfare adopted even by persons in the same service, that to enter upon the investigation of the subject in all its bearings, and throughout its amplifications, would be to comprise a volume of no small magnitude. We must, therefore, content ourselves with observing, that the ordinary disposition for an engagement, where no particular *point d'appui* is in question, consists of two or more lines, composed chiefly of infantry, properly supported by artillery of various natures, that is to say, of brass 18 pounders, also of 12, 9, 6, and 3 pounders, with a portion of howitzers, commonly of  $4\frac{1}{2}$ , or  $5\frac{3}{4}$  inches diameter in the bore, or eventually up to 8 inches. These are placed in the intervals between the several regiments, while one or more parks of artillery are arranged in such parts of the several lines, as may appear to require that powerful aid; or on such commanding spots as may enable the artilleryists to act with greater effect against the enemy. See *TACTICS, Military*.

Where the ground may admit, the cavalry often commences the action, by endeavouring to prevent the enemy from forming upon, or taking possession of, strong positions. The horse artillery, together with the pieces of lighter construction which can be speedily withdrawn, advance to cannonade; while the infantry may be deploying from column into line, or forming according to the instructions of the generals commanding in the several quarters of the army; to whom the commander in chief previously communicates his intentions. During this time, the greatest order, coolness, and promptness, are indispensably necessary: it is now that superior discipline will manifest itself, and that the real powers of an army will be ascertained. Let it not,

however, be supposed, that that kind of symmetrical order which is the boast of our parade *martinets*, is to be found in the field of battle! Far otherwise; in lieu of regular firings by divisions, each individual loads and discharges his piece when, and how he can; in place of a regulated pace conforming to any particular cadence, the advances and retreats are generally too much divested of that order, and of that systematic uniformity, which so highly delight the fair sex when they visit our summer camps, to witness the splendid array attendant upon parade evolutions. In short, the celebrated song in the "Recruiting Serjeant" is the best, and most pithy description of an engagement we have ever heard, especially that part which relates to the most arduous portions of the contest.

" But the merriest joke of all,  
Is when to close attack we fall.  
Killing, wounding, maiming, butting,  
Dashing, flashing, slaying, cutting:  
Horse and foot,  
Both go to't;  
Blood and thunder!  
Then to plunder,  
Oh! what a charming thing's a battle!"

A very charming thing, indeed; especially when we consider that many of the wounded are often murdered by persons, chiefly women, who follow the several armies, for the purpose of plundering such unfortunate brave men as may be incapable of making resistance. It is, indeed, a well-known fact, that this iniquitous and disgraceful practice, is more than ever prevalent in many countries, whose inhabitants, being at least on a par with those of the most enlightened parts of the world, should rather endeavour to soften the rigours of war, than to perpetrate the most savage cruelties on those whose misfortune it may be to be disabled in the course of an engagement.

These fluctuations between victory and defeat, which sometimes alternate for hours together between contending armies, must afford the most lively interest to a spectator, and cannot fail to produce the most exquisite sensations of joy, or of misery, in the breasts of the respective commanders. What can afford a greater gratification than the complete success of an army? or what can occasion more pointed chagrin than the evidence of its defeat? Perhaps, of all the men who ever experienced such reverses, the old king of Prussia may be considered as the most illustrious instance of fortitude under disaster, and of moderation when successful. These good qualities, though they may have been coeval with his birth, must necessarily have been considerably enhanced, by that intense application the monarch paid to the discipline of his army. Hence, we are informed, that no reverse appeared to him irremediable, and that no victory was considered by him to be permanent. Such a man must have viewed an engagement under very peculiar impressions: he must have been most ardently intent upon the consideration of what evolutions would be most suited to the events passing under his notice; while at the same moment, his mind must have been actively employed in the consideration of resources, wherewith he might, according to the modern cant term, "carry on the war." We must, however, remark, that the great Frederick rarely had a large army; but that which he had, though comparatively small, was of immense strength: every part was systematically organized under the most severe code of discipline, and under the most penetrating observation. We have heard old officers state, that the Prussian army, under their immortal royal general, performed its evolutions, and preserved the

## ENGAGEMENT.

the same order, and went through their firings, as regularly while in action as when on their several parades. We fear this singular instance of military consistency, is not likely to be again displayed by the Prussian army at this date; nor, indeed, have we any authority, if past events are to guide us, for expecting to see, or hear, that they should throughout an engagement display those qualities which, however much we may commiserate the sufferings of those individuals whereof it was composed, characterized the military establishment of that now ill-fated country! We leave to our readers to contemplate what must be the feelings of the brave marshal Mollendorff, who, we believe, is the only surviving general now of the many that held commands under that military prince, whose existence in these times would, no doubt, have given a very different aspect to the affairs of Europe.

ENGAGEMENT, in a *Naval Sense*, denotes a particular or general battle at sea, or an action of hostility between single ships, or detachments, or squadrons of men of war: the whole economy of which may be arranged under the heads of preparation, action, and repair. The preparation is begun by issuing the order to clear the ship for action, which is repeated by the boatswain and his mates at all the hatchways. The hammocks are first removed; every sailor stowing his own bedding properly and firmly cording it with a lashing, or line provided for that purpose: as each side of the quarter deck and poop is furnished with a double network, supported by iron cranes fixed immediately above the gunnel or top of the ship's side; the hammocks, thus corded, are firmly stowed by the quarter-master between the two parts of the netting, so as to form an excellent barrier or fort of parapet, to prevent the execution of small shot on the quarter-deck: the tops, waite, and fore-castle, are fenced in the same manner.

At this time all heavy luggage, such as chests, &c. are handed down into the hold, and the surgeon, with his mates and assistants, together with whatever women may be on board, descend into a part called the cock-pit; which, being below the level of the water, is considered to be tolerably secure; various instances have, however, been known of shots, between wind and water, finding their way to that retirement.

At the same time the boatswain and his mates are employed in securing the sail-yards, to prevent them from tumbling down when the ship is cannonaded, whereby it might be disabled. The yards are secured by strong chains or ropes, besides those by which they are usually suspended. The boatswain also provides the necessary materials for repairing the rigging; and the carpenter and his crew prepare shot-plugs and mauls to close up any breach that may be made near the surface of the water, and provide their iron-works necessary to refit the chain-pumps. The gunner, with his mates and quarter-gunners, examine the cannon of the different batteries, and provide proper charges, &c. The master and his mates attend to the mending and trimming of the sails, &c. The lieutenants visit the different decks, taking care that all incumbrances are removed, and giving instructions to the other officers, that every thing may be ready for the expected engagement at a moment's warning. When the hostile ships have approached each other to a competent distance, the drums beat to arms: the boatswain and his mate pipe "all hands to quarters!" at every hatch-way. The persons appointed to manage the great guns immediately repair to their respective stations; crows, hand-spikes, rammers, sponges, powder-horns, matches, and train-tackles are placed in order by the side of every cannon. The hatches are laid to prevent any one from creeping into the lower

apartments. The marines are drawn up in rank and file, on the quarter-deck, poop, and fore-castle. The lashings of the great guns are let loose, and the tompions withdrawn: the whole artillery, above and below, is run out at the ports, and levelled to the point-blank range ready for firing. When the necessary preparations are finished, the commencement of the action is determined by the mutual distance and situation of the adverse ships, or by the signal from the commander in chief of the fleet or squadron. The cannon being levelled in parallel rows, projecting from the ship's side, the most natural order of battle is evidently to range the ships a-breast of each other, especially if the engagement is general. The most convenient distance is probably within the point-blank range of a musket, so that all the artillery may do effectual execution. The combat usually begins by a vigorous cannonade, accompanied with the united efforts of all the swivel-guns and small arms. Instead of firing platoons, or volleys of cannon at once, the general rule throughout the ship on these occasions is to load, sponge, and fire the guns with all possible expedition, yet without confusion or precipitation. The captain of each gun is enjoined to fire only when the piece is properly directed to its object. The lieutenants who command the different batteries traverse the deck, to see that the battle is prosecuted with vigour, and to animate the men in their duty. The midshipmen second these injunctions, and give assistance where it is required at the guns committed to their charge. The gunner takes care that the artillery is supplied with powder, and that the cartridges are conveyed along the decks in covered boxes.

During the action, the captain manœuvres his ship to the best advantage; causing the master so to lay her on the enemies' bows, or quarters, and especially under her stern, as may give those favourable results attendant upon a safe, but annoying, position. Should any intervals arise, owing to the situations of the several ships, it is employed in clearing the decks, in repairing the damaged rigging, and in providing for a renewal of the engagement. If, as very often happens, the enemy make sail with the view to escape, the guns are secured, while all hands turn to for the purpose of giving chase: in this instance, the great object is to come up with the flying foe; therefore all these sails which were furled or clued up, with the intention of either having less to manage, or to keep them free from danger, are now spread to the gale, and every effort is made to regain a position within such a distance as may cause the enemy to strike his flag, and to surrender. Should he still persist, the engagement must continue, until, being a complete wreck, he may consider further opposition useless. So soon as he has struck, his ship is taken possession of by a detachment from the victor's crew, and the whole of the subdued party are put under hatches in the hold, or, if necessary, are otherwise secured in the bilboes, &c. while a prize master, generally a lieutenant, is put on board, for the purpose of navigating the prize, according to such orders as he may receive.

It sometimes happens, that, where an enemy is very determined, it is necessary to board; indeed, this not unfrequently occurs, owing to vessels adventitiously coming in contact. Previous to the adoption of this desperate measure, it will be absolutely necessary to consider well how far it may be likely to succeed. If the opposing crew be numerous, and especially if abounding in marines, or if there be any number of military on board, much management, activity, and resolution will be required to carry the point; which is generally effected by laying along the lee waite or quarter, or perhaps upon the bow, and, after having grappled,

grappled, by means of chains, or of small boarding grap-nails suspended by chains from the yards, to lower down the boarding platforms, (if there be any,) and thus to rush upon the enemy's deck. In some instances, ships have been boarded by entering at the ports, stern, or quarter gallery, &c. either of which modes will often succeed, where the whole of the opposing crew rush with too much precipitation, to the upper works, with the intention of resisting those who are about to board upon the deck. The bowsprit is frequently resorted to, as the means of entering an enemy's ship: this, being laid over the stem, or taffrail, will generally enable the boarders to proceed with sufficient facility, while the marines are employed in keeping up a sharp fire, to drive the defenders off the poop. It is, however, a very hazardous concern, and chiefly resorted to on desperate occasions, by privateers, or where, though strong in point of crew, a vessel may not be of sufficient force to lie alongside her opponent. A repulse in boarding is peculiarly dangerous, and very commonly leads to defeat. It almost invariably happens, that, on such occasions, great numbers of the boarders are destroyed; whereby the residue of the ship's company are considerably dispirited; at least, this is an ordinary result among foreigners; British tars are not so easily daunted, but may be again, and again, led to the attack.

When the engagement is concluded, they begin the repair. The cannon are secured by their breachings and tackles; the sails that have been rendered unserviceable, are unbent; and the wounded masts and yards struck upon the deck, and fished or replaced by others. The standing rigging is knotted, and the running rigging spliced wherever this is necessary. Proper sails are bent in the room of those that are become useless. The carpenter and his crew repair breaches in the ship's hull by shot-plugs, pieces of plank, and sheet-lead. The gunner and his assistants replenish the allotted number of charged cartridges, and refit the damaged furniture of the cannon.

When two fleets or squadrons are preparing for engagement, it will be the endeavour of the admiral or commander in chief to come to action as soon as possible. To facilitate the execution of the admiral's orders, the whole fleet is ranged into three squadrons; each of which is classed into three divisions, under the command of different officers. Before the action begins, the adverse fleets are commonly drawn up in two lines parallel to each other, and close-hauled. When the admiral displays the signal for the line of battle, the several divisions separate from the colours in which they were disposed according to the usual order of sailing, and every ship crowds into its station in the wake of the next a-head, at the distance generally of about fifty fathom; which distance is regularly observed from the van to the rear: though the admiral may sometimes find it necessary to contract or extend his line, according to the length of that of his adversary; always taking care that his own line be secure from being doubled, which might throw his van and rear into confusion. When the reverse fleets approach each other, the courses are commonly hauled up in the brails, and the top-gallant sails and stay-sails, furled; the frigates, tenders, and fire-ships, being hauled upon the wind; lie at some distance behind the line of battle; and transports and store ships lie beyond these, at a still greater distance from the scene of action; and if the number of ships allows it, a body of reserve from the different squadrons is selected to cover the fire-ships, &c. and stationed opposite to the weakest parts of the line, so that they may readily fall into the line in case of necessity. Each ship forming the line should keep close to its station during the engagement; the assault of

boarding being seldom permitted unless in single action: because the regularity of a close line constitutes the principal force of the fleet; and the skill of the admiral is greatly concerned in keeping his line, notwithstanding unequal attacks and damage, as complete as possible. If he proves victorious, he should prosecute his victory as much as possible, by seizing, burning, or destroying the enemies' ships. If he is defeated and reduced to the necessity of retreating, he may judge it expedient, for greater security, to range his fleet into the form of a half-moon, placing himself in the centre. The enemies' ships that attempt to fall upon his rear will thus be exposed to the fire of the admiral and his seconds, and the escape of his own ships will be facilitated, whilst the pursuit of his adversary is retarded. Upon the whole, the real force of superiority of a fleet, consists less in the number of vessels and the vivacity of the action, than in good order, dexterity in working the ships, presence of mind, and skilful conduct in the admiral and captains. Falconer's Marine Dict. art. *Engagement*.

There formerly existed certain supposed axioms, in regard to the several modes of forming in line of battle a-head, or a-breast; and much attention was paid to the weather-gage, as well as to other such matters: fleets used then to manoeuvre for several days, obviously intent upon gaining some particular position, which was supposed to be indispensably necessary towards a successful issue. Of late years this has been totally, or at least very generally neglected; for in lieu of fleets, or single ships, now dancing minuets for such a purpose, we see them ranging up with little ceremony, and intent only on getting into action; whatever may be the state of the wind or of the weather. All that a British commander requires of his master, nowadays, is, "Lay me alongside the enemy;" a few guns more or less, or even an extra deck, on the part of the enemy, being disregarded. It is to this spirit, that our shores are indebted for safety, and our commerce to that wide range afforded by the universal command which Britain holds over the ocean. It is with the utmost pride and satisfaction, we witness the glorious exertions of our invincible tars: for such we may fairly designate men who, regardless of every danger, and urged by the most patriotic zeal, bear away the palm when, and wherever the enemy, however superior in guns, or in numbers, give them the opportunity of displaying that valour which, though uncontrollable in opposing a foe, is rapidly metamorphosed into humanity, so soon as the victory may be proclaimed, or that the voice of distress may be heard! Surely we never can sufficiently reward those heroes who, as Hudibras says, stand forward—

"To fight our battles in our steads,  
And have their brains beat out o' their heads;  
Encounter in despite of nature,  
And fight at once with fire and water,  
With pirates, rocks, and storms, and seas."

A naval engagement is a branch of warfare in which the British character appears to the utmost advantage, and in which we stand confessedly pre-eminent over the whole universe. We derive the more satisfaction, from the reflection, that our credit and prowess are not ephemeral, nor dependant upon any temporary weakness on the part of our opponents: we contemplate them as heir-looms, bequeathed to us from a noble and brave ancestry, whose examples have been duly followed, and whose reputation has, no doubt, contributed to that zeal, and to that emulation, which pervade every part of the British navy, and induce our tars to persevere in their struggles for the preservation of our rights and liberties as a people; while,

at the same time, each individual aims to uphold his own character for bravery, subordination, and generosity. See **BATTLE**, **BOARDING**, **LINE of Battle**, and **SIGNAL**.

**ENGAGEMENT**, in *English History*, was the obligation imposed by Oliver Cromwell required to be signed by every member of the First Parliament in 1654, assembled by his authority, after he was declared Protector, viz. "I. A. B. do hereby freely promise and engage myself to be true and faithful to the Lord Protector, and to the commonwealth of England, Scotland, and Ireland, and shall not (according to the tenure of the indenture whereby I am returned to serve in this present parliament) propose or give any consent to alter the government, as it is settled in one single person and a parliament." Many, who refused to sign this engagement, were excluded from the house.

**ENGALLA**, in *Zoology*, the Ethiopian hog or African wild boar. See *Sus Æthiopicus*.

**ENGALLIM**, in *Ancient Geography*, a town of Judea, in the tribe of Benjamin, situated on the coast of the Dead sea, where, according to St. Jerom, the river Jordan discharged itself into that sea.

**ENGAMOS**, in *Natural History*, the name given by the people of some parts of Guinea to a root very common there, and much resembling our larger sort of turnips, but not so sweet or juicy. They commonly boil these with their battatas, in the same kettle with their meat. The latter of these roots, which is considerably different from our potatoe, gives a fine flavour to the whole, and makes the broth and meat taste as if rose-water were added to it. The engamos also partakes of the flavour, and in this case becomes very agreeable. Phil. Trans. N<sup>o</sup> 108.

**ENGANNIM**, in *Ancient Geography*, a city in the plain belonging to Judah, Josh. xv. 34.—Also, a city of Issachar; given to the Levites of Gerihon's family. Josh. xix. 21. xx. 29.

**ENGANNO**, or **DECEIT Island**, in *Geography*, an island in the Eastern sea, at a small distance from the S.W. coast of the island of Sumatra. S. lat. 5 9'. E. long. 102° 44'.

Ships that pass the straits of Sunda, in the westerly monsoon, generally run in sight of Enganno. This island is 6 or 7 leagues in length, and not quite half as broad. It is not high, and can only be discerned at the distance of 5 leagues. It is covered with trees, and always appears green. For a more particular account of this island, see Phil. Trans. for 1778.

**ENGANO, CAPE**, a cape on the east coast of the island of St. Domingo. N. lat. 18° 27'. W. long. 68° 52'.

**ENGANO**, or **ENGANNO, Cape**, the N.E. point of the island of Luçon, in the East Indian sea. N. lat. 17° 45'. E. long. 121° 20'.

**ENGASTRIMANTES**, *Ἐγαστρίμαντες*, in *Antiquity*, called also *Engastrimythi*, *Ἐγαστρίμυθοι*, a designation given to such diviners as were possessed with demons, which either lodged or spoke within their bodies. Pott. Archæol. Græc. lib. ii. cap. 12. tom. i. p. 301.

**ENGASTRIMYTHUS**, *Ἐγαστρίμυθος*, or *Engastrimander*, a person who speaks from, or with the belly, without opening his mouth; or, if open, without stirring the lips.

Thus called by the Greeks, from *ἔγαστρον*, belly, and *μῦθος*, speech; and by the Latins, *ventriloquus*, quasi *ex ventre loquens*.

The ancient philosophers, &c. are divided on the subject of the *engastrimythi*: Hippocrates mentions it as a disease. Others will have it a kind of divination, and ascribe the

origin and first discipline thereof to one Euryelus, whom nobody knows any thing of. Others attribute it to the operation or possession of an evil spirit; and others, to art and mechanism.

The most eminent *engastrimythi* were the Pythians or priestesses of Apollo, who delivered oracles from within, without any action of the mouth or lips.

St. Chrysostom and Occumenius make express mention of a sort of divine men, called by the Greeks *engastrimandri*, whose prophetic bellies pronounced oracles.

M. Schottus, library-keeper to the king of Prussia, in a Dissertation on the Apotheosis of Homer, maintained that the *engastrimythi* of the ancients were only poets; who, when the priests could not speak in verse, supplied the defect, by explaining or delivering in verse what Apollo dictated in the cavity of the basin, placed on the sacred tripod.

Leo Allatius has an express treatise on the *engastrimythi*. See **VENTRI-LOQUISTS**.

**ENGEDI**, in *Ancient Geography*, *q. d.* the fountain of the goat, called also *Hazazon-Tamar*, or the palm-tree city, from the great quantity of palm-trees that surrounded it, a city of Palestine, in the tribe of Judah (Josh. xv. 62.), situated near the lake of Sodom, 300 furlongs from Jerusalem, not far from Jericho, and the mouth of the river Jordan. It was in a cave of the wilderness of Engedi, that David had an opportunity of killing Saul, and of sparing his life, then in pursuit of him. 1 Sam. xxiv. 1, 2, 3; &c.

**ENGEL**. See **ANGLEN** and **ANGLES**.

**ENGELACH**, in *Geography*, a town of Germany, in the circle of Lower Saxony; and bishopric of Hildesheim; 15 miles S.W. of Alfeld.

**ENGELBERG**, an extensive narrow valley of Switzerland, in the canton of Underwalden; its length exceeds twelve miles, and it is hardly six miles broad. It was formerly called the *Hahnenberg* (Cocks' mountain), but when the abbey church was consecrated, some inhabitants pretended they had heard the melodious concerts of the angels in heaven, which made them call it *Engelberg*, (the Angels' mountain). The inhabitants are numerous and remarkable for the innocence of their manners, and for their hospitality to strangers.

The abbey of Engelberg is 9 miles S.W. of Altorf. It was founded in the year 1125.

**ENGELBRECHTS**, a town of Germany, in the archduchy of Austria; 95 miles N.N.W. of Bavarian Waidhoben.

**ENGELHARTZEL**, a town of Germany, in the archduchy of Austria; 9 miles E. of Passau.

**ENGELHAUS**, a town of Bohemia, in the circle of Saatz; 2 miles E.S.E. of Carlsbad.

**ENGELHOLM**, a town of Sweden, in the province of Schonen, or Scania, situated at the mouth of a river which runs into the Cattegat, 12 miles from Helsingborg. It is the twentieth town in rank among those which vote in the Swedish diet. Its name is said to be derived from the Angles, who either first came from this neighbourhood, or passed over to it from Denmark, and built the place for the convenience of trade. The latter conjecture is the most probable.

**ENGELSBURG**, a town of Silesia, in the principality of Appau; 5 miles N.N.W. of Freudenthal.

**ENGELSBURG**, a small town of Prussia, in the district of Culm, with an ancient castle not far from Graudontz.

**ENGELSDORF**, a town of Bohemia, in the circle of Boleslaw; 10 miles N.N.E. of Krottau.

**ENGELSTEIN**,

ENGELSTEIN, a town of Prussia, in the province of Natangen; 48 miles S.E. of Königsberg.

ENGELSTETTEN, a town of Germany, in the archduchy of Austria; 23 miles E. of Vienna.

ENGEN, a town of Germany, in the circle of Swabia, and principality of Stullingen; 12 miles N.N.E. of Schaffhausen, and 20 N.N.W. of Constance.

ENGENDERING, or INGENDERING, the act of begetting or producing the kind, by way of generation.

The term is likewise applied to other productions of nature: thus, meteors are said to be engendered in the middle region of the air. Crude fruits engender worms. The ancients believed, that insects were engendered of putrefaction.

ENGENTHAL, in *Geography*, a town of Germany, in the circle of Franconia; 13 miles E. of Nuremberg.

ENGER, a town of Germany, in the kingdom of Westphalia, and county of Ravensburg; 3 miles W. of Herwarden.

ENGER Sea, a lake of Carinthia, 10 miles N.N.W. of Feltkirchen.

ENGERSTORFF, a town of Germany, in the archduchy of Austria; 10 miles S.W. of Zistersdorf.

ENGETAL, a valley of Switzerland, in the canton of Basle, remarkable for its abbey, which was secularized in 1534, and where a bible was printed at the end of the fifteenth century, with N. Lyra's notes.

ENGGISTEIN, a small town of Switzerland, one mile from Worbe, remarkable for its mineral springs, on whose account it is much visited in the summer season. The water contains a little copper. The accommodations of the place are very good.

ENGHELBRECHT, CORNELIUS, in *Biography*, a painter, born at Leyden in 1468. Having imitated the works of John Van Eyck, at Bruges, he returned to his own country, and had the honour of being the first who taught the Dutch to paint in oil; in which he wrought with very great reputation in his time, as well as in distemper; and was then accounted among those most deserving of estimation.

He was not quite so dry or formal in his manner of design as the painters of that period; and he cast his draperies with more care, and better style, than they. His most admired performance is the representation of the "Lamb" in the Revelation, which he painted for a chapel in the church of St. Peter at Leyden. The composition consists of an immense crowd of figures, angels, martyrs, doctors, and fathers of the church, &c. and all the "holy hierarchy of heaven," combined together with an immense multitude of persons of all nations. This picture is very ingenious in the painting of the various parts, but it must owe its reputation more to the lack of knowledge of the better qualities of art at the time it was painted, than to its own intrinsic worth. This artist died in 1533, at 65.

ENGHIEN, or ENGUIEN, in *Geography*, a small town of France, in the department of Jemmappe, chief place of a canton, in the district of Mons, with a population of 3045 individuals. It is 18 miles S.W. of Brussels, and 15 N. of Mons. N. lat. 50° 40'.

The canton contains 10 communes, and 13,674 inhabitants, on a territorial extent of 140 kilometres. It is from this place that the eldest sons of the princes of Condé in France, the last of whom was so basely murdered by the orders of the French emperor Napoleon, derived the title of duke.

ENGINIA, an island near the coast of the Morea, an-

ciently called *Ægina*, which see. *Ægia* gives name to a gulf on the S.E. coast of European Turkey, formerly denominated *Sinus Saronicus*. See *ÆGINA*.

ENGINE, in *Mechanics*, a compound machine, consisting of several simple ones, as wheels, screws, levers, or the like, combined together, in order to lift, call, or sustain a weight, or produce some other considerable effect, so as to save either time or force.

The word is formed of the French *engine*; of the Latin *ingenium*, wit; because of the ingenuity required in the contrivance of engines, to augment the effect of moving powers.

The kinds of engines are innumerable; some for war, as the ballista, catapulta, scorpio, aries, &c. others for the arts of peace, as mills, cranes, presses, clocks, watches; engines to drive piles, to bore cannon and water-pipes, (see BORING), to raise water, wheel and water-works; to extinguish fire, see FIRE-engine, &c. See HYDROCANISTERIUM. See STEAM-engine, &c. See also INSTRUMENT.

ENGINE for cutting Wheels. See CUTTING-Engine.

ENGINE for cutting Fusées. See FUSEE-Engine.

ENGINE for ornamenting a Watch-case. See ROWS-Engine, or ROSE-Engine.

ENGINE for dividing Circles, Quadrants, Sextants, and Octants. It is not our intention in this place to enter into the history of the different methods of dividing astronomical instruments into degrees and their sub-divisions, as successively practised by Tycho Brahe, Hevelius, Dr. Hook, Mr. Abraham Sharp, Olaus Roemer, Mr. Graham, Mr. Jon. Sisson, Mr. Bird, Mr. Ramsden, and Mr. Troughton, without the aid of an engine; but, as we propose to treat the subject at some length under our article GRADUATION of *Astronomical Instruments*, we beg leave to refer the reader to that head for such particulars as relate to the manual operations performed by the beam-compass and otherwise, which are necessary for graduating all circles and other instruments, that are too large to be graduated by an engine.

Among all the improvements in chronometers and nautical instruments, that owed their origin, during the last century, to the munificent encouragement of the honourable Board of Longitude, there is none that has so much contributed to the interest of navigation, considered as a science, as the engine at present to be described; the facility, and at the same time the accuracy, with which the measuring portion of any nautical instrument, however portable, can now be divided by our best engines, are truly astonishing; the fine dividing-strokes, which, in many instances, are scarcely visible to, and not legible by the naked eye, when magnified by a suitable lens, are perceived to be laid down with such perfect equality, as to relative distances, that no one who has not examined the means by which they were effected, can conceive the possibility that the expedition, with which the divisions are made, is equal to the accuracy with which they are measured and marked down. In Mr. Smeaton's paper, read to the Royal Society of London, on Nov. 17, 1785, on the "Graduation of Astronomical Instruments," he mentions an engine, made by Mr. Henry Hindley of York, which indented the edge of any circle in such a way, that a screw with fifteen threads acting at once, would, by means of a micrometer, read off any given number of divisions, so as to answer the purpose of sub-dividing the circle. It does not, however, appear that this engine, though it divided the circles of Hindley's equatorial instruments, was intended or adapted so much for graduating circles as for cutting the teeth of wheels in clock-work. (See CUTTING-Engine.) The year in which it was seen by

## ENGINE.

by Mr. Smeaton was 1741, and, consequently, was in Graham's time, who died in 1751. According to the same author, Mr. Ramsden, in consequence of the reward offered by the Board of Longitude to Mr. Bird, for his method of dividing, in the year 1760, turned his thoughts towards the contrivance of an engine that would divide nautical instruments with sufficient accuracy, without the tediousness of manipulation. Accordingly, considering the nature and properties of the endless screw, and probably contemplating what Hindley had previously done in this way, he completed an engine with an indented plate, or wheel, of thirty inches diameter, which, though it did not completely answer his expectations to their full extent, yet was found very useful for dividing theodolites and such common instruments with great facility. This was effected before the spring of 1768, and, in 1774, a much larger and better engine was produced, with an indented plate of 45 inches diameter, which divided a sextant for Mr. Bird's examination so accurately, that the Board of Longitude, ever ready to remunerate any successful endeavour to promote the lunar method of determining the longitude at sea, did not hesitate to confer an handsome reward on the inventor, but on condition that the said engine might be at the service of the public, and that Mr. Ramsden would publish an explanation of his method of making and using it, which he accordingly did in a quarto pamphlet in the year 1777. The sum of money given to Mr. Ramsden was 615*l.*, of which 300*l.* was considered as a reward for his improvement in the art of dividing instruments by means of his engine, and the remaining 315*l.* was paid in consideration of his making over the property of the said engine to the Commissioners of Longitude, for the good of the public. The description which Mr. Ramsden published, being short and explicit, cannot well be abridged, and the drawings, intended as a guide for other artists to work by, are explanatory of all the parts of the engine, as detached from one another; we have therefore given reduced engravings of all the figures, as they were originally arranged, and propose to copy the description without any other alteration than what the references to our plates required.

*Mr. Ramsden's Engine.*—“This engine consists of a large wheel of bell-metal, supported on a mahogany stand, having three legs, which are strongly connected together by braces, so as to make it perfectly steady; *fig. 1. Plate VII. of Engines*, is a perspective representation of the body thus united. On each leg of the stand is placed a conical friction-pulley, whereon the dividing-wheel rests: to prevent the wheel from sliding off the friction-pulleys, the bell-metal centre under it turns in a socket on the top of the stand. The circumference of the wheel is ratched or cut, by a method to be hereafter described, into 2160 teeth, in which an endless screw acts. Six revolutions of the screw will move the wheel a space equal to one degree. Now a circle of brass being fixed on the screw-arbor, having its circumference divided into 60 parts, each division will answer to a motion of the wheel of ten seconds; six of them will be equal to a minute, &c. Several different arbors of tempered steel are truly ground into the socket in the centre of the wheel. The upper parts of the arbor, that stand above the plane, are turned of various sizes, to suit the centres of different pieces of work to be divided. When any instrument is to be divided, the centre of it is very exactly fitted to one of these arbors, and the instrument is fixed down to the plane of the dividing wheel, by means of screws, which fit into holes made in the radii of the wheel for that purpose. The instrument being thus fitted on the plane of the wheel, the frame which carries the dividing-point is connected at one

end by finger-screws with the frame which carries the endless screw; while the other end embraces that part of the steel arbor which stands above the instrument to be divided, by an angular notch in a piece of hardened steel; by these means both ends of the frame are kept perfectly steady and free from shake.

The frame carrying the dividing-point, or tracer, is made to slide on the frame which carries the endless screw to any distance from the centre of the wheel, that the radius of the instrument to be divided may require, and may be there fastened by a pair of clamps; and the dividing-point, being connected with the clamps by the double-jointed frame, admits a free and easy motion towards or from the centre, for cutting the divisions without any lateral shake. From what has been said it appears, that an instrument thus fitted on the dividing-wheel may be moved to any angle by the screw and divided micrometer circle on its arbor, and that this angle may be marked on the limb of the instrument with the greatest exactness by the dividing-point, which can only move in a direct line tending to the centre, and is altogether freed from those inconveniences that attend cutting by means of a straight edge. This method of drawing lines will also prevent any error that might arise from an expansion or contraction of the metal, during the time of dividing. The screw-frame is fixed on the top of a conical pillar, which turns freely round its axis, and also moves freely towards or from the centre of the wheel, so that the screw-frame may be entirely guided by the frame which connects it with the centre: by these means any eccentricity of the wheel and the arbor would not produce any error in the dividing; and by a particular contrivance, hereafter described, the screw, when pressed against the teeth of the wheel, always moves parallel to itself; so that a line joining the centre of the arbor and the dividing-point, continued, will always make equal angles with the screw. The rest of the parts are represented in *Plates VIII. and IX. of Engines*, where the figures are numbered in succession from 2 to 14 inclusively, which are more easily referred to than the figures in the original plates. *Fig. 2* is a plan of reduced dimensions, of which *fig. 3* represents a section on the line  $\Pi A$ . The large wheel, *A*, is 45 inches in diameter, and has 10 radii, each supported by edge-bars, as seen in *fig. 3*. These bars and radii are connected by the circular ring *B*, 24 inches in diameter, and 3 deep; and, for greater strength, the whole is cast in one piece in bell-metal. As the whole weight of the wheel, *A*, rests on its ring *B*, the edge-bars are deeper where they join it; and from thence their depth diminishes, both towards the centre and circumference, as seen in the figure. The surface of the wheel, *A*, was worked very even and flat, and its circumference turned true. The ring *C*, of which a section is seen in *fig. 3*, made of fine brass, was fitted very exactly on the circumference of the wheel, and was fastened thereon with screws, which, after being screwed as tight as possible, were well rivetted. The face of a large chuck being turned very true and flat in the lathe, the flattened surface, *A*, of the wheel was fastened against it with hold-fasts; and the two surfaces and circumference of the ring *C*, a hole through the centre, and the plane part round it, together with the lower edge of the ring *B*, were all turned at the same time. *D* is a piece of hard bell-metal, having the hole that receives the steel-arbor made very straight and true. This bell-metal was turned very true on its arbor, and its face, that rests against the wheel, was made very flat, so that the steel-arbor might stand perpendicular to the plane of the wheel: this bell-metal was fastened to the wheel by six steel screws. A brass socket, *Z*, is fastened on the centre of the mahogany stand,

## ENGINE.

and receives the lower part of the bell-metal piece D, being made to touch the bell-metal in a narrow part near the mouth, to prevent any obliquity of the wheel from bending the arbor: good fitting is by no means necessary here, since any shake in this socket will produce no bad effect, as will appear when the cutting-frame is described. The wheel was then put on its stand, the lower edge of the ring, B, resting on the circumference of the three conical friction-pulleys W, to facilitate its motion round its centre. The axis of one of those pulleys is in a line joining the centre of the wheel and the middle of the endless screw, and the other two placed so as to be at equal distances from each other. F is a block of wood (*fig. 1.*), strongly fastened to one of the legs of the stand; the piece, *g* (*figs. 1 and 12.*), is screwed to the upper side of the block, and has half holes, in which the transverse axis, *b*, (*figs. 1 and 11.*) turns; the half holes are kept together by the screws *i*. The lower extremity of the conical pillar, P, (*figs. 1 and 11.*) terminates in a cylindrical steel pin *k*, which passes through and turns in the transverse axis *b*, and is confined by a cheek and screw. To the upper end of the said conical pillar is fastened the frame G, (*figs. 5 and 9.*), in which the endless screw turns; the pivots of the screw are formed in the manner of two frusta of cones joined by a cylinder, as represented at X, in *fig. 9.* These pivots are confined between half holes, which press only on the conical parts, but do not touch the cylindrical parts; the half holes are kept together by screws, *a, a*, which may be tightened at any time, to prevent the screw from shaking in the frame. On the screw-arbor is a small wheel of brass, K, having its outside edge divided into 60 parts, and numbered at every 6th division with 1, 2, &c. to 10. The motion of this wheel is shewn by the index, *y*, on the screw-frame G. H represents part of the stand (*fig. 1.*) having a parallel slit in the direction towards the centre of the wheel, large enough to receive the upper part of the conical brass pillar P, which carries the screw and its frame; and as the resistance, when the wheel is moved by the endless screw, is against that side of the slit, H, which is towards the left hand, that side of the slit is faced with brass, and the pillar is pressed against it by a steel spring on the opposite side: thus is the pillar strongly supported laterally, and yet the screw may be easily moved from or against the circumference of the wheel, and the pillar will turn freely on its axis, to take any direction given it by the frame L, lying over the wheel in *fig. 1.* and seen more distinctly in *fig. 13.*

At each corner of the piece I, seen in *fig. 1.* and also detached in *fig. 8.* are as many screws, *n*, of tempered steel with polished conical points: two of them turn in conical holes in the screw-frame, near *o*, *fig. 9.*; and the points of the other two turn in holes in the piece Q, *fig. 7.*: the small end screws, *p*, are of steel, which, being tightened, prevent the conical pointed screws from unturning, when the frame is moved. The brass frame L, *figs. 1 and 13.* serves to connect the endless screw, its frame, &c. with the centre of the wheel; each arm of this frame is terminated by a steel screw, that may be passed through any of the holes, *q*, in the piece Q, *fig. 7.* as the thickness of the work to be divided on the wheel may require, and are fastened by the finger-nuts *r*, seen in *figs. 1 and 2.* At the other end of this frame is a flat piece of tempered steel *b*, wherein is an angular notch: when the endless screw is pressed against the teeth of the circumference of the wheel, which may be done by turning the finger-screw S, seen in *figs. 1 and 2.* to press against the spring *t*, this notch embraces and presses against the steel-arbor *d*. This end of the frame, too, may be raised or depressed, by moving the tri-

angular or prismatic slide *u* (*fig. 14.*), which may be fixed at any height by the four steel screws *v*. The bottom of this slide has a notch *k*, having its plane parallel to the endless screw; and by the point of the arbor *d*, resting in this notch, this end of the frame is prevented from tilting: the screw, S, also is kept fast by the finger-nut *w*, in *fig. 2.*

The teeth on the circumference of the wheel were cut by the following method. Having considered what number of teeth on the circumference would be most convenient, which in this engine is 2160 or  $360 \times 6$ , I made, says Mr. Ramden, two screws of the same dimensions of tempered steel, the interval between the threads of which being such as I knew by calculation would come within the limits of what might be turned off the circumference of the wheel; one of these screws, which was intended for ratcheting or cutting the teeth, was notched across the threads, so that the screw, when pressed against the edge of the wheel and turned round, cut in the manner of a saw. Then having a segment of a circle a little greater than  $60^\circ$ , of about the same radius with the wheel, and its circumference made true from a very fine centre, I described an arch near the edge, and set off the chord of  $60^\circ$  on this arch. This segment was substituted for the wheel, and had its edge ratched or indented; and the number of revolutions and parts of the screw head contained within the arch of  $60^\circ$  were counted. The radius was corrected in the proportion of 360 revolutions, which ought to have been in  $60^\circ$ , to the number actually found; and the radius so corrected was taken in a pair of beam compasses: while the wheel was on the lathe, one foot of the compasses was put in the centre, and with the other a circle was described on the ring; then half the depth of the threads of the screw being taken in the dividers, was set from this circle outwards, and another circle was described cutting this point; a hollow was then turned on the edge of the wheel of the same curvature as that of the screw, at the bottom of its threads; the bottom of this hollow was turned to the same radius as the outward one of the two circles before-mentioned.

The wheel was now taken off the lathe, and the bell-metal piece D, *fig. 3.* was again screwed to its place; not to be removed any more. From a very exact centre, a circle was described on the ring C, *fig. 4.* about  $\frac{1}{16}$ ths of an inch within where the bottom of the teeth would come; this circle was divided with the greatest possible exactness, first into 5 parts, and each of these again into 3; these parts were then bisected 4 times; *i. e.* supposing the whole circumference of the wheel to contain 2160 teeth, a fifth part would be 432, a fifteenth part (or  $5 \times 3$ ) would be 144, and this last number bisected four times would give 72, 36, 18, and 9 respectively; but as it was apprehended that some inaccuracy would arise from quinquesection and trisection, another circle was described on the same ring, at  $\frac{1}{16}$ th of an inch within the former circle, and divided by continual bisections into the portions 2160, 1080, 540, 270, 135,  $67\frac{1}{2}$ , and  $33\frac{3}{4}$ ; and as the fixed wire, to be described presently, crossed both the circles, it was a check on their agreement at every 135 revolutions, and after ratcheting at every  $33\frac{3}{4}$ ; but as no sensible difference was perceived in the two circles, the former was chosen for ratcheting: and as the coincidence of the fixed wire with an intersection would be more exactly determined than with a dot or division, the intersections in both circles were used.

The arms of the frame L, *figs. 1 and 13.* were connected by a thin piece of brass  $\frac{1}{4}$  of an inch broad, having a hole of  $\frac{1}{16}$ ths of an inch diameter in the middle; across this hole a silver wire was fixed exactly in a line to the centre of the wheel;

## ENGINE.

wheel; the coincidence of this wire with the intersections was examined by a lens of  $\frac{7}{8}$ ths of an inch focus, fixed in a tube, that was attached to one of the arms L. Now a handle, or winch, being fixed on the end of the screw-arbor, the division marked 10 on the circle K was set to its index, and, by means of a clamp and adjusting screw for that purpose, the intersection marked 1 on the circle C was set exactly to coincide with the fixed wire; the screw was then carefully pressed against the circumference of the wheel, by turning the finger-screw S; then, the clamp being removed, the screw was turned by its handle just 9 revolutions, till the intersection marked 240, *fig. 4*, came nearly to the wire; the finger-screw S was now turned back, and the dividing screw released from the edge of the wheel, which was here turned back till the intersection marked 2 exactly coincided with the wire; the division 10 on the micrometer circle was then set to its index as before, and the screw pressed against the edge of the wheel by the finger-screw S; then, the clamps being removed, the screw was turned a second 9 revolutions, till the intersection marked 1 nearly coincided with the fixed wire; the screw was again released, and the same operation was repeated till the teeth were faintly marked all round the circumference of the wheel. The impression was made deeper by thus going three times round; after which the wheel was ratcheted continually round 300 times in the same direction, without disengaging the screw, when the teeth were found sufficiently indented. Now, it is evident, that, if the circumference of the wheel were even a whole tooth or ten minutes space greater than the screw would require, this error would, in the first instance, be reduced to  $\frac{1}{240}$ th part of a revolution, or two seconds and a half; and these errors or inequalities of the teeth were equally distributed round the wheel at the distance of 9 teeth from each other; but, as the screw in ratcheting had continually hold of several teeth at the same time, and as these were constantly changing, the above-mentioned inequalities soon corrected themselves, and the teeth were reduced into a perfect equality.

The piece of brass which carries the wire was now taken away, and the cutting-screw also removed, and replaced by the plane one of the same dimensions; on one end of its arbor was put the micrometer circular plate divided into 60, and numbered at every six divisions, as already stated; and on the other end was placed a ratchet-wheel of 60 teeth, seen in *fig. 6*, which is covered by the hollowed circle *d*, carrying two clicks, that catch upon the opposite sides of the ratchet, when the screw is to be moved forwards. The cylinder S, *figs. 5* and 9, turns on a strong steel arbor F, seen in *fig. 5*, which passes through, and is firmly screwed to the piece Y; this piece, for greater firmness, is attached to the screw frame G by the braces *v*: a spiral groove or thread is cut on the outside of the cylinder S, which serves both for holding the string, and also for giving motion to the lever J on its centre, *figs. 9* and 10, by means of a steel tooth *n* that works between the threads of the spiral. To the lever is attached a strong steel pin *m*, *fig. 10*, on which a brass socket *t* turns: this socket passes through a slit in the piece *p*, and may be tightened in any part of the slit by the finger-nut *f*: this piece serves to regulate a number of revolutions of the screw for each tread of the treadle R, seen in *fig. 1*. T, in *fig. 1*, is a brass box, containing a spiral spring: a strong gut is fastened and turned three or four times round the circumference of this box; the gut then passes several times round the cylinder S, *figs. 1* and 9, and from thence down to the treadle R. Now, when the treadle is pressed down, the string pulls the cylinder S round its axis, and the clicks laying hold of the teeth on the ratchet, carry the

screw round with it, till, by the tooth *n* working in the spiral groove, the lever J is brought near the wheel *d*, *fig. 6*, and the cylinder is stopped by the screw-head *x*, *fig. 9*, striking on the top of the lever J: at the same time the spring is wound up by the other end of the gut passing round the box T, *fig. 1*. Now, when the foot is taken from the treadle, the spring in the box unbending itself, pulls back the cylinder, the clicks leaving the ratchet and attached screw at rest till the piece *t* strikes on the end of the piece *p*, *fig. 10*; and the number of revolutions of the screw at each tread is limited by the number of revolutions that the cylinder is allowed to turn back before the stop strikes on the piece *p*. When the endless screw is moved round its axis with a considerable velocity, it will continue that motion a little after the cylinder S is stopped; to prevent which angular motion, the angular lever *n* was made, that when the lever J comes near to stop the screw *x*, it, by a small chamfre, presses down the piece *x* of the angular lever; this brings the other end *n* of the same lever forwards, and stops the endless screw by the steel pin *u* striking on its top; the foot of the lever is again raised by a small spring pressing on the brace *v*.

Two clamps D, *fig. 13*, connected by the piece *a*, *fig. 1*, slide, one on each arm of the frame L, and may be fixed at pleasure by the four finger-screws *e*, which press against steel springs, to avoid spoiling the arms; the piece *q*, *fig. 13*, is made to turn without shake between the two conical pointed screws *f, f*, set fast by the finger-nuts N, N. The piece M is made to turn on the piece *q*, by the conical pointed screws resting in the hollow centres *e, e*. As there is frequent occasion to cut divisions on inclined planes, for that purpose the piece *g*, in which the tracer or dividing point is fixed, has a conical axis at each end, which turn in half holes; so that when the tracer is set to any inclination, it may be fixed there, by tightening the steel screws  $\beta\beta$ .

Subsequently to the time of Mr. Ramsden's dividing engine being constructed, Mr. Edward Troughton constructed one to answer the same purpose, which it does in the most perfect manner; and it was our intention to have described it also in this place, but on application to him for permission to inspect its parts and manner of operating, we were sorry to learn that he has pledged himself to give an account of it himself in another work.

ENGINE (by Ramsden) for cutting the Screws of the circular Dividing-Engine.—We mean not to enter here into the history of the screw-engine, as it may be, and has been applied to various purposes, but to describe the engine made and used by Mr. Ramsden for making the individual screws which he used for ratcheting his engine for dividing circles, &c., and for measuring the angular distance on his circle when ratcheted. This apparatus, indeed, may be considered as an appendage to the other, and therefore ought to be introduced in this place. *Fig. 1*, of *Plate X*, of *Engines*, represents this engine as seen from one side of reduced dimensions; and *fig. 2*, the same as seen from above, of the same dimensions. A represents a triangular bar of steel, to which the triangular holes in the pieces B and C are accurately fitted, and may be fixed on any part of the bar by the screw D. E is a piece of steel whereon the screw is intended to be cut, which, after being hardened and tempered, has its pivots turned in the form of two frustra of cones, as represented in the drawings of the dividing-engine. These pivots were very exactly fitted to the half holes F and T, which were kept together by the screws Z. H represents a screw of untempered steel, having a pivot I, which turns in the hole K. At the other end of the screw is a hollow centre, which

## ENGINE.

receives the hardened conical point of the steel pin M. When this point is sufficiently pressed against the screw, to prevent its shaking, the steel pin may be fixed by tightening the screws Y. N is a cylindrical nut, moveable on the screw H, which, to prevent any shake, may be tightened by the screws O. This nut is connected with the saddle-piece P, by means of the intermediate universal joint W, through which the arbor of the screw H passes. A front view of this piece, with a section across the screw-arbor, is represented at X, *fig. 3*. This joint is connected with the nut by means of two steel slips S, which turn on pins between the checks T, on the nut N. The other end of these slips S turn in like manner on pins *a*. One axis of this joint turns in a hole in the cock *b*, which is fixed to the saddle-piece, and the other turns in a hole *d*, made for that purpose in the same piece on which the cock *b* is fixed. By these means, when the screw is turned round, the saddle-piece will slide uniformly along the triangular bar A. K is a small triangular bar of well-tempered steel, which slides in a groove of the same form on the saddle-piece P. The point of this bar or cutter is formed to the shape of the thread intended to be cut on the endless screw. When the cutter is to take proper hold of the intended screw, it may be fixed by tightening the screw *e*, which presses the two pieces of brass G upon it. Having measured the circumference of the dividing-wheel, it was found to require about one thread in a hundred, coarser than the guide-screw H. The wheels on the guide-screw arbor H, and that on the steel arbor E, on which the screw was to be cut, were proportioned to each other to produce that effect, by giving the wheel L 198 teeth, and the wheel Q 200. These wheels communicated with each other by means of the intermediate wheel R, which also served to give the threads on the two screws the same direction. The saddle-piece P is confined on the bar A by means of the pieces *g*, and may be made to slide with a proper degree of tightness by the screws *n*.

*ENGINE for cutting the Screw of Ramsden's Engine for dividing Straight Lines.*—The exactness of the straight line engine, as made by Ramsden, depends very much on the correctness of the endless screw, which requires some properties that are not absolutely necessary in the endless screw for the circular engine. In that, as there are but a few threads of the endless screw engaged in the teeth of the wheel; it required only that those threads should have a similar inclination to the axis of the screw all round; but in the straight-line engine, where the whole length of the screw is engaged in the moveable plate, it is necessary that the distances also between the threads should be precisely the same throughout the whole length of the screw: as this is effected in a manner in some respects different from the mode of cutting the screw we have just described, we shall subjoin it here, that the reader may take a comparative view of the two methods adopted, by that great artist Ramsden. In *fig. 1*, of *Plate XI*, of *Engines*, is a plan of the engine for cutting the screw for dividing straight lines; and in *fig. 2*, is an elevation of the same. The section, as given in the original account published in 1779, does not seem to be necessary for explaining the engine, and is therefore omitted in our account. A, in *fig. 1*, represents a strong circular plate of brass, having its edge ratched, as described in our account of the circular dividing-engine; on its centre is firmly fixed the pulley B by four screws, having a groove turned on its cylindrical part, perfectly concentric with the plate A. C, in *fig. 2*, is a steel axis two feet long, terminating in a point, whereon it rests; the upper part of the axis being firmly screwed to the plate A, and turning in the collar D.

E represents an endless screw, *fig. 1*, which being turned on its horizontal axis, moves the circular plate A round its centre: F is a circular divided small plate, or micrometer-head, which may be turned with or without the endless screw; and on the other end of this screw-arbor is a large pinion *a*, with levelled teeth on its edge, together with the winch X to turn it by. G, seen in both figures, is a triangular bar of steel, which passes over the circular plate A, and is firmly screwed to the frame of the engine at H, *fig. 1*, and I, *fig. 2*. K is a piece of steel forming the arbor of the screw intended to be cut, having a wheel L, on one end acting with the pinion *a* before-mentioned. M and N, *fig. 1*, are two strong pieces of brass, in which the arbor just mentioned turns, and are firmly fixed to the triangular bar G, by means of the screws *n, n*, seen at I, in *fig. 2*. O, seen in both figures, is a piece of brass that slides on the triangular bar G, the two extremities of which are made exactly to fit the bar; it slides regularly thereon, and is prevented from rising by the two spring pieces *c, c*; near one end of the piece O is an angular groove *q*, *fig. 1*, that holds the tool by which the threads are cut, and is pointed with a diamond, in order to cut the steel after it is hardened and tempered: the cock *w* serves to fasten the tool, which may be set to take proper hold on the steel by turning the finger-screw *s*, and is fixed there by the screw *v*.

To make a perfect screw, it is only required to give the point that cuts the threads an uniform motion parallel to itself, and also to the axis of the intended screw, and that this motion be proportioned to the revolutions of the intended screw as the number of threads may require. To effect this, a piece of thin tempered steel *t*, exactly of the same thickness throughout, is fastened to the slide O at *r*; the other end of the spring being fastened to the pulley B in the groove: now while the circle A, with the pulley, is turned round its centre by turning the endless screw to the right hand, the spring *t* draws the slider O, with the attached cutter *q*, along the triangular bar; at the same time the steel-arbor K of the screw to be cut revolves by means of the communication of its wheel L with the revolving pinion *a*.

The screw, E, of the circular plate has 20 threads per inch, therefore if the number of teeth on the pinion, *a*, be to the number in the wheel L, as the number of teeth on the circular plate, A, is to the number of 20ths of an inch round the circumference of the pulley B, allowing for part of the thickness at the spring *t*, the spaces between each of the threads of the screw to be cut will be also 20ths of an inch. The size of the pulley, B, was determined thus: the endless screw, E, being disengaged from the circular plate A, the slider, O, was drawn back till the end of it came nearly to the piece M; the endless screw was again engaged in the plate A; then having two very small dots on the slider O, set off parallel to one side, at exactly five inches distance from each other, the slider was moved by turning the endless screw E, till one of its dots was bisected by a small silver wire fixed across a hole made in a thin piece of brass fast to the piece N; then O on the micrometer head, F, being put to the index without moving the screw, the pulley was tried and reduced, till just 600 revolutions of the endless screw, E, brought the second dot to be exactly bisected by the fixed wire. These bisections were examined by a lens of half an inch focus, set in a small brass tube, that was fixed perpendicularly over the wire.

*ENGINE for dividing straight Lines, by Ramsden.*—When Mr. Ramsden had succeeded in dividing sextants, &c. by his circular dividing engine, and was rewarded by the honourable Board of Longitude, he turned his mind towards

## ENGINE.

wards the contrivance of an engine that would divide straight lines into any number of assignable parts, and that might be useful in laying down with extreme accuracy the lines of fines, tangents, secants, &c. on sectors and plane scales. The project was realized, and the account was ordered to be published by the Board of Longitude, in the year 1779. We do not find, however, that the original model, which we come now to describe, has been found desirable to copy by succeeding mathematical instrument makers: more simple and less expensive means have been adopted, which are found to answer practically as good a purpose. A beam-compass, aided by proper tables, is quite accurate enough for the nicest purposes of dividing unequal, as well as equal, divisions by bisection; and a pattern once carefully laid down can be used, for transferring the divisions on the common cases of instruments, with greater facility than the engine itself can be worked; and, provided great care be taken to prevent the parallax of the transferring point, the accuracy will be sufficient for all ordinary uses. This engine, which professes to divide any line without an error of  $\frac{1}{10000}$ th of an inch, has its principal parts represented in *Plate XII. of Engines*; where *fig. 1*, represents a plan of the dividing portion, as seen from above; *fig. 2*, an elevation of the same seen across; and *fig. 3*, the under side of *fig. 1*, when turned up. The original account contains some sections, which are more useful for the workmen as patterns, than for a general description, which may dispense with them altogether. *A*, in *fig. 1*, is a strong brass plate, 27 inches long, 4 broad, and  $\frac{1}{7}$ ths thick; worked exceedingly flat, and of the same thickness throughout, with its two edges parallel. One of these edges is ratched, or cut into teeth, of which there are just 20 in an inch, and is moved by an endless screw, containing just 20 threads in an inch, which actuates the teeth. (See *ENGINE for cutting the Screw of Ramsden's straight-line Engine*.) Each revolution of the endless screw round its axis will move the plate  $\frac{1}{1000}$ ths of an inch along an iron frame, hereafter to be described. A micrometer head is fixed at one end of the screw arbor, divided into 50 divisions, which, by means of a vernier subdividing into 5 parts, measures  $\frac{1}{10000}$ ths of an inch along the frame. Any rule or other instrument may be fastened on this plate, and may have a line drawn on it divided by a point or tracer, fixed in a proper frame, whereby it has a rectilinear motion without any lateral shake. When lines are to be divided by divisions not commensurable with English inches, which constitute the scale, the line to be so divided may be laid down, not parallel to the plate *A*, but obliquely, so as to make an angle with it, or become the hypotenuse line of a right-angled triangle; which line, by calculation, shall be to the base as the denomination of measure, when longer, is to the English inch; that is, as the secant is to the radius of the triangle, provided the tracer draws lines at right angles to the side of the plate; but if the traced lines be at right angles to the line to be divided, then the divisions on that line will be shorter than they would be on a parallel line of the plate, and in the proportion of the co-sine of the angle of inclination to radius. In order to adjust the inclination of a ruler laid on the plate *A*, two sectoral portions of a circle are laid down on one of its ends, with an extent from the point *J*, near the fixing screws on the edge of this plate. The outer sector is divided into proper degrees, and is numbered from 1 to 9, which degrees are subdivided into 6, or 10 minutes spaces; but the inner sector is divided into the proportion of the co-sines to radius 10,000, and its divisions are numbered 10, 20, 30, &c. to 140. The use of this contrivance will be best understood by an example: for instance, if a line of

$9\frac{1}{2}$  inches were to be divided into the same number of divisions, and in the same manner as if it were 10 inches long exactly; put the ruler to be divided to the cutting frame, hereafter described, and turn the handle, *T*, that moves the apparatus, till the same edge of the ruler cuts the central point *J*, and the first division from the *O* of the inner sector; then screw the ruler fast to the plate *A*, and when it has moved ten inches in its own direction, the whole length of the divisions on the line divided will be only  $9\frac{1}{2}$  inches, though the divided spaces will be respectively equal among themselves. It is not necessary for us to particularize the precautions taken, in making all the spaces of the teeth ratched equal to each other, during the act of ratching, which was done with a notched screw: this was done by means of points previously made and examined, with a wire at every 16 revolutions of the screw, till the teeth were a little indented to guide the screw along the whole line by continual revolutions, as was the case in the circular dividing instrument, more particularly described, because found more particularly useful. *B*, in *fig. 1*, is a strong iron frame, 43 inches long, having two edges, *a* and *b*, rising half an inch above its surface; these two edges are made very straight, and are in the same plane; the inside of the edge *a* is also made as straight as possible. The plate, *A*, slides on the two edges of the iron frame; beneath it are two springs, *c, c*, seen in *fig. 3*, each fastened at the extreme ends to the plate *A*, by the screws, *s, s*; at the other end of each spring is a roller, *e*, of tempered steel, turning on an axis in these springs; there is also a third roller, *d*, of tempered steel, let into the iron frame, not seen, near where the threads of the endless screw act; this roller has a long axis, so situated that it may be raised or depressed as occasion may require, to bear the weight of the plate *A*, and rule or instrument placed on it. *C*, in *figs. 1* and *2*, is the endless screw of tempered steel, with pivots of two sorts of inverted cones, similar to those described in the engine for dividing circles, &c. which turn in adjustable half holes in brass cocks screwed to the iron frame. *G, G*, in *fig. 3*; are two small steel frames turning on centres, *k*, fastened to the under side of the plate *A*, and equidistant from the edge of it; in each frame is a roller, *y*, of tempered steel, turning very concentric with their pivots, and exactly of the same diameter. The two small frames are connected together by the long brass bar *E*, which turns on a stud in each frame, and which preserves its parallelism, on the principle of a common parallel ruler. This apparatus serves to press the edge of the plate, *A*, with a motion parallel to itself against the threads of the endless screw. On the end of the plate, *A*, is a spring of tempered steel, acting as a bent lever. The spring end of this lever has a ketch which passes under the head of the stud *l*, that is on the end of the connecting piece *E*. While the other end of the lever is pressed gradually down towards the plate *A*, by turning the finger-screw *F*, the connecting piece, *E*, is drawn forward, so that the steel rollers, borne by the springs *T*, in *fig. 3*, pressing against the edge, *a*, of the iron frame, in *fig. 1*, may force the side of the plate against the endless screw.

Besides the micrometer head, already named, the arbor of the dividing screw, which has its threads similar to those of the notched ratching screw, has at its opposite end two sets of ratched wheels; one set for turning the screw, and the other set for stopping it at the proper times. These sets are each composed of three wheels, of which one has 32 teeth, another 48, and the third 50, which afford the means of subdividing the inch into spaces of different denominations; those wheels used in stopping the screw are ratched, with the teeth pointing in a contrary direction to those

those of the wheels for putting it in motion. I represents a cylinder of brass, having on one end two steel rings, *a* and *b*, with their contiguous edges cut into ratched teeth, in contrary directions, so as to fit each other as seen in the figure; on one of these rings is an index, and the other has its teeth numbered 10, 20, &c. up to 50; the other end of the cylinder is made hollow, and contains one of the sets of ratched wheels, already named. There are two slits opposite each other, pierced through the hollow part of the cylinder *W*; in each of which slits is a click turning on an axis, and pressed into the teeth of the ratched wheel by a small spring; these clicks may be moved along their axis, so as to catch in any one of the three ratched wheels, and may be fastened at that place by a small tightening screw *s*. The cylinder *I*, with the clicks, &c. turns on a steel axis, attached to the piece *K*, in a line with the axis of the endless screw. Motion is given to this cylinder round its axis by a piece of catgut, which hath one end fastened to the ratched ring *b*; and the other end, after passing four or five times round the cylinder, is fastened to a treadle, and, on pressing the treadle down, the clicks, *s*, catch in the teeth of one of the ratched wheels; by which contrivance the cylinder *I*, together with the endless screw, is turned round its axis, and its motion carries the plate, *A*, along the iron frame, and at the same time winds up the spiral spring *u*; but on releasing the treadle, the said spring unbends itself, the clicks quit the ratched wheel, and leave the endless screw at rest, whilst the cylinder, *I*, turns in an opposite direction, and raises the treadle to its former situation. *V*, in *fig. 2*, is a small square bar of steel, having both its extremities cylindrical; these cylinders move in holes lined with hardened steel, one in the piece *D*, and the other in the piece *K*. This bar carries three different pieces, which are of tempered steel; the middle one, *t*, is made to lie in the interval between the threads of the screw cut on the cylinder, and passes nearly half round its circumference: it is kept in the threads by a spring, *e*, that presses on a piece, *g*, screwed to the iron frame; this piece being attached to the bar, *V*, by a screw, turning the cylinder, *I*, on its axis, will give a longitudinal motion to the bar *V*. The upper end of the piece *f*, *fig. 2*, is formed into a hook, and may be set to catch in the teeth of any of the ratchet wheels, and then be fastened to the bar, *V*, by a screw *i*; towards the other end of the bar is a piece *j*, which serves to stop the cylinder in turning back, so as to limit the number of revolutions and parts of a revolution required, and is fastened to any required place on the bar, *V*, by the finger-screw *s*.

When the engine is used, the treadle is pressed down, and the catgut turns the cylinder *I*; in the mean time, the piece, *t*, moves along the thread till a stud, *r*, on the cylinder, striking on the top of the curved piece *t*, bends the spring *e*, until that piece rests on the piece *g*; by bending this spring, the square bar is turned a little on its axis, and pulls the hook, *f*, into the teeth on the ratched wheel *R*: then the treadle being released, the spiral spring turns back the cylinder till the piece, *j*, is brought under the stop on the ratchet ring *b*. The parts of a revolution are regulated by setting the number required on the ratchet ring, *b*, to the index on the fixed ring *a*; each of the teeth answers to the motion of  $\frac{1}{100}$ th of an inch of the plate *A*; and the number of revolutions, each of which moves the plate, *A*,  $\frac{1}{10}$ ths of an inch, is regulated by setting the piece, *j*, on the bar. *I*, in *fig. 1*, represents the steel frame in which the tracer is fixed; this frame turns between the conical points of two screws, *n, n*, of tempered steel, which are screwed in the frame *Q*, *fig. 2*; there are also two similar

screws in the same frame *Q*, at *m, m*; the points of these screws, which are also of tempered steel, turn in conical holes in the piece *P*; by means of this parallel motion, the tracing point, by which the dividing lines are cut, will always describe the same line without any lateral bending; the tracer is put on the hole in the axis *b*, *fig. 1*, and is fixed there by the four tightening screws, *f*, that press the holding piece, *e*, against the flattened part of the axis of motion. This small axis, which has its pivots formed of double cones, turns between half holes, and may be fixed when the tracer is set to any required inclination, by tightening the screws of pressure, *s, s, s, s*. Besides these parts of the engine, there is a brass ruler made as an appendage for setting the line to be divided in its true situation, but is not necessary to be particularly described: this ruler may be set parallel to the edge of the plate *A*, or to any angle of inclination, by turning the handle *T*, which moves the piece *P*, with the cutting frame and ruler, on the centre *x*; and the required position may be rendered permanent by tightening the capstan screw *p*.

*ENGINE-Shaft*, in *Mining*, is generally applied to the shaft or well wherein the pumps are erected for freeing a mine of its water; but in districts where the mines are relieved of water by soughs, as in the mountainous part of Derbyshire, it is common to find the shafts at which they draw ore by a horse-gin, called the engine-shaft, and the gin itself an engine.

*ENGINE to draw Fuzes*, in *Gunnery*, consists of a wheel with a handle to it, to raise a certain weight, and to let it fall upon the driver, by which the strokes become more equal.

*ENGINE to draw Fuzes* has a screw fixed upon a three-legged stand, the bottom of which has a ring to place it upon the shell; and at the end of the screw is fixed a hand-screw, by means of a collar, which, being screwed on the fuze, by turning the upper screw, draws out or raises the fuze.

*ENGINEER*, or *ENGINEER*, in its general sense; is applied to a contriver or maker of any kind of useful engines or machines.

In its more proper sense, it denotes an officer in an army or fortified place, whose business it is to contrive and inspect attacks, defences, works, &c. The term engineer is said to be of modern date, and to have been first used in the year 1650, when one Cap. Thomas Rudd had the title of chief engineer to the king. In 1634 an engineer was called camp-master general, and sometimes engine-master, being always subordinate to the master of the ordnance.

An engineer should be an able and expert mathematician, particularly versed in military architecture and gunnery; being often sent to view and examine the places intended to be attacked; to choose out and shew the general the weakest place; to draw the trenches, assign the places of arms, galleries, lodgments on the counter-scarp and half-moons; conduct the works, saps, mines, &c. and appoint the workmen their nightly task; he is also to make the lines of contravallation; with the redoubts, &c.

Under the establishment of the office of his majesty's ordnance in England, the corps of *royal engineers* consists of one colonel in chief, one colonel in second, three colonels commandant, six colonels, 12 lieutenant-colonels, 27 captains, 28 second-captains, 55 first-lieutenants, 28 second-lieutenants, an inspector-general of fortifications, his deputy brigade-major, adjutant, and quarter-master.

The establishment of the corps of *invalid engineers* comprehends a colonel, lieutenant-colonel, captain, captain-lieutenant and captain, first-lieutenant and second-lieutenant.

The corps of *royal engineers* in Ireland consists of a director, colonel, lieutenant-colonel, major, captain, captain-lieutenant, and captain, and two first-lieutenants. See **ORDNANCE**.

**ENGINEERS, Civil**, a denomination which comprises an order or profession of persons highly respectable for their talents and scientific attainments, and eminently useful under this appellation, as the canals, docks, harbours, light houses, &c. amply and honourably testify. This order of artists is said to have commenced in this country about the year 1760, at which period the advancement of the arts and sciences was singularly rapid. In 1771, Mr. Smeaton, so well known in this department of science, projected and established an association, or society of engineers. During an interval of 20 years, the number of members of this society increased to 65, of whom 15 were real engineers, and the residue being composed either of amateurs, or of ingenious workmen and artificers. In May 1792 this society was dissolved in consequence of an unpleasant circumstance, which had interrupted its harmony; but a renewal of it, under a better form, was soon intended, though not accomplished during the life-time of Mr. Smeaton. His death happened in October 1792, and the first meeting of the new institution, entitled "The Society of Civil Engineers," was held on April 15, 1793, by Mr. Jessop, Mr. Mylne, Mr. Rennie, and Mr. Whitworth. According to the new constitution of the society, it is divided into three classes. The first class, as ordinary members, consists of real engineers. The second class, as honorary members, is composed of men of science, and gentlemen of rank and fortune, who have attended to the subject of civil engineering. The third class, as honorary members also, consists of artists, whose professions and employments are connected with what is called civil engineering. The meetings are held at the Crown and Anchor, in the Strand, every other Friday, during the session of parliament. See Reports of the late Mr. John Smeaton, F.R.S. &c. vol. i. 4to. 1797.

**ENGISOMA**, from *επισημα*, to draw near, in *Surgery*, an instrument formerly used by surgeons in cases of fractures of the skull. Hence, the word has been applied to such fractures of the cranium as are attended with a depression of the bone in the middle, so as to produce pressure on the membranes of the brain.

**ENGLAND**, in *Geography*. The southern, most opulent, and most important part of Britain, has been distinguished among European nations, ever since the days of venerable Bede, by the appellation of "Anglia," or England; which has been generally ascribed to the Angles, who conquered and took possession of a considerable part of the country. (See **ANGLIEN**, **ANGLES**, and **CimbriC CHERSONESUS**.) England is bounded on the east by the German ocean; on the south by the English channel; on the west by St. George's channel; on the north by the Cheviot hills, by the river Tweed, and an imaginary line extending south-west to the Frith of Solway. The extent of England and Wales is estimated at 49,450 square miles, and if we allow the population to be 9,500,000, the number of inhabitants to a square mile will be 192. The original population of England is involved in obscurity; but as far as it can be traced by any authentic records of history, it seems to have consisted of a tribe of Celts (see **CELTS**), denominated Gael or Southern Celts, and distinguished by the Welsh under the appellation of "Guydels," who migrated hither from the nearest shores of France and Flanders. These southern Celts were compelled to evacuate the country, and to retire to Ireland, by another tribe, composed of the Cimbri of the

north, whence the modern Welsh derive their origin and name of Cymru. The Cimbri, or Northern Celts, were displaced by the Scythians, or Goths, who, at a period long preceding the Christian era, settled in that part of Gaul which is nearest to Great Britain, and acquired the provincial denomination of Belgæ. (See **BELGÆ**.) We learn from Cæsar (lib. v. c. 10.) that the primitive inhabitants were driven into the interior parts of the country by Belgic colonies, which occupied the regions on the south-east, probably about three centuries before the Christian era. These Belgæ seem to have constituted the chief ancestors of the English nation; but during a subjection of four centuries to the Roman power, after Britain was rendered a Roman province by the talents and virtue of Agricola, (see **AGRICOLA**,) they lost their primitive valour, and were unable to contend with their fierce invaders from Scotland and Ireland. In these circumstances the continent supplied them either by accident or at their own request, with new emigrants. The Jutes arrived in the year 449, and about the year 460 founded the kingdom of Kent. The Saxons first appeared in 477, and the kingdom of the South Saxons commenced about this period. The West Saxons arrived in the year 495, and the East Saxons in the year 527. The Angles, who gave their name to the country, were led by the valiant Ida to Bernicia, in the year 547. The East Angles took possession of Norfolk in 575; and the coasts on the south and east were over-run by them. Hence they soon penetrated into the interior of the country, and in 585 founded the kingdom of Mercia, which was the last of the heptarchy. (See **HEPTARCHY** and **SAXONS**.) The kingdom of Northumberland existed under its peculiar sovereign, the last of whom was Eric, till the year 950; and the three counties of modern Northumberland, Cumberland, and Westmoreland, were regarded at that period, when *Domesday-book* was compiled, as part of Scotland. Bernicia (which see) extended at one period to the Frith of Forth; but in the later Saxon times the boundaries of England on the north fell considerably within the present extent. On the west the Welsh were restricted by Offa's dyke, (see **DYKE**), which extended from the river Wye, through the counties of Hereford and Radnor, into that of Montgomery, where it entered North Wales. It afterwards passes by Chirk-castle to the river Dee, and terminates in the parish of Mold. During the Norman period, the northern limits of England were extended to their present circuit. Cumberland and Westmoreland were wrested from the Scots, and the provinces north of the Humber were completely incorporated. The dominion of the Danes commenced in the year 1016, but returned to the Saxon line in the year 1042. On the death of Edward the Confessor, the conquest, as it is called, under William the Norman, took place in 1066. (See **CONQUEST**.) For a farther account of the history of England, see **BRITAIN**, and the sequel of this article.

The antiquities of England are distributed by Mr. Pinkerton (*Geog.* vol. i.) into six classes, *viz.* those belonging to the primitive Celtic inhabitants; those of the Belgic colonies; those of the Romans; those of the Saxons; relics of the Danes; and Norman monuments. It is not easy, says our author, to discriminate the remains of the earliest inhabitants from those of the Druidic period, which he supposes to have originated with the Phœnician factories, established in wooden fortresses on the coast, which was the usual practice of commercial nations, when trading with a savage or barbarous race. The tenets of Druidism correspond, as he conceives, with the little that is known of Phœnician mythology, in the diffusion of which the missionaries of these refined people might be not a little zealous. However this

# ENGLAND.

be, the ancient authors, from whom we derive our only authentic information concerning the Druids, minutely describe their religious rites; but they are altogether silent concerning any monuments of stone being used among them. On the contrary, they mention gloomy groves, and spreading oaks, as the only scenes of the Druidic ceremonies. (See DRUIDS.) Nevertheless, our learned antiquarian, Borlase, refers to the class of Druidic monuments such as follow, viz. single stones erect; rock idols and pierced stones; rocking-stones used as ordeals; sepulchres of two, three, or more stones; circular temples, or rather circles of erect stones; rock-basins, supposed to have been used in the expiations of the Druids; and caves, used as places of retreat in time of war. But Mr. Pinkerton observing, that most of these relics may be found in Germany, (where no Druids existed,) and Scandinavia, thinks it hazardous to pronounce whether they be Gothic or Celtic. It is most probable, he imagines, that the earliest inhabitants, like others who exist in the infancy of society, made use of wood, not stone, in their religious, as well as in their domestic structures. He thinks it most reasonable to refer monuments of this kind to a more advanced stage of society, when the Belgic colonies introduced agriculture, and had made somewhat farther progress in the rude arts of barbarism. See BARROW and CROMLECH, STONE-HENGE, &c.

The Roman relics are amphitheatres, castles, ways, or roads, pavements, hypocausts, walls, inscriptions, altars, &c. &c. which are described under these articles respectively; to these we might add coins, gems, weapons, ornaments, and the like. The Saxon antiquities in England are chiefly edifices, sacred or secular, castles, vaults, shrines, illuminated manuscripts, &c. The relics of the Danes are castles, stones with Runic inscriptions, and camps, which were constructed in a circular form, like those of the Belgæ and Saxons, while those of the Roman armies are distinguished by their square form. The Norman monuments are reputed to commence after the conquest, and to extend to the 14th century, when that which is called the rich Gothic began to appear. This latter was supplanted, in the 16th century, by the mixed, which in its turn yielded to the Grecian. The Norman style in general far exceeds the Saxon in the size of the edifices, and the decorations of the parts. The churches became more extensive and lofty; and though the windows retain the circular arch, they are larger and more diversified, the circular doors are festooned with more freedom and elegance; and uncouth animals begin to yield to wreaths of leaves and flowers. The solitary keep, or tower, of the Saxon castle, is surrounded with a double wall, inclosing courts and dwellings of large extent, defended by turrets and double ditches, with a separate watch-tower, called the Barbican. Among others the cathedrals of Durham and Winchester may be mentioned as venerable monuments of Anglo-Norman architecture; and the castles are numerous and well-known. What is called the Gothic, or pointed arch, is generally supposed to have first appeared in the 13th century; and in the next it became universal in religious edifices. The windows diffused to great breadth and loftiness, and divided into branching interstices, enriched with painted glass, the clustering pillars of excessive height, spreading into various fret-work on the roof, constitute, with decorations of smaller note, what is called the rich Gothic style, visible in the chapel of King's college at Cambridge, and many other grand specimens in this kingdom. The spire corresponds with the interior; and begins, about the 13th century, to rise boldly from the ancient tower, and diminishes from the sight in a gradation of pinnacles and ornaments. See GOTHIC.

England is now distributed into 40 shires or counties. See COUNTY and SHIRE.

	Population.	Chief Towns.
Six Northern Counties.	Northumberland,	157,101 Newcastle.
	Cumberland,	117,230 Carlisle.
	Durham,	160,361 Durham.
	Yorkshire,	563,953 York.
	Westmorland,	41,617 Appleby.
Four bordering on Wales.	Lancashire,	672,731 Lancaster.
	Cheshire,	191,751 Chester.
	Shropshire,	167,639 Shrewsbury.
	Herefordshire,	81,191 Hereford.
Twelve Midland.	Monmouthshire,	45,582 Monmouth.
	Nottinghamshire,	140,350 Nottingham.
	Derbyshire,	161,142 Derby.
	Staffordshire,	239,153 Stafford.
	Leicestershire,	130,081 Leicester.
	Rutlandshire,	16,356 Okeham.
	Northamptonshire,	131,757 Northampton.
	Warwickshire,	208,190 Warwick.
	Worcestershire,	139,333 Worcester.
	Gloucestershire,	250,809 Gloucester.
	Oxfordshire,	109,620 Oxford.
	Buckinghamshire,	107,444 Aylesbury.
Bedfordshire,	63,393 Bedford.	
Eight Eastern.	Lincolnshire,	208,557 Lincoln.
	Huntingdonshire,	37,568 Huntingdon.
	Cambridgeshire,	89,346 Cambridg.
	Norfolk,	273,371 Norwich.
	Suffolk,	210,431 Ipswich.
	Essex,	226,437 Chelmsford.
	Hertfordshire,	97,577 Hertford.
	Middlesex, (capital excluded,)	535,329 London.
Three Southern.	Surry,	269,043 Guilford.
	Kent,	307,624 Maidstone.
	Suffex,	159,311 Lewes.
Four Southern.	Berkshire,	109,215 Reading.
	Wiltshire,	185,107 Salisbury.
	Hampshire,	219,656 Winchester.
	Dorsetshire,	115,319 Dorchester.
Three Southern.	Somerfeshire,	273,750 Taunton.
	Devonshire,	343,001 Exeter.
	Cornwall,	188,269 Launceston.

For a more particular account of each county, see the separate articles.

It is hardly necessary to mention, that London is the capital of England, or in this place to enumerate its principal towns, which are described under their several appellations. Canterbury and York are the sees of archbishops: Oxford and Cambridge are universities. The principal rivers of England are the Thames, the Severn, the Humber, the Mersey, &c. which feed respectively. For an account of our inland navigation, see CANAL; and for our bridges, see BRIDGE. The mountains with their productions, will occur under that article. For the climate, see BRITAIN; and of the soil, and agriculture, &c. an account will be found under the name and description of each county; and under the appropriate terms of cattle, dog, hog, horse, sheep, goats, &c. and wheat, rye, barley, oats, apples and cyder, pears and perry. Our forests (see FOREST) anciently abounded in stags and rein-deer, as the cultivated lands now do with sheep and cattle. The principal wild animals, wolves and bears having been totally destroyed,

destroyed, are the fox, wild-cat, badger, fitchet, martin, otter, squirrel, &c. Among our birds of prey may be reckoned the black eagle, and many kinds of hawks. Our smallest bird is the gold-crested wren, and our largest the bustard. Our poultry seem to have been originally derived from Asia; our peacocks from India; our pheasants from Colchis; the guinea fowl from Africa; and our turkeys from America. One of the most singular of our water-fowl is the long-legged plover, and the most useful is the mallard or wild duck, chiefly abounding in the fens of Lincolnshire. The reptiles of England are the coriaceous tortoise, frogs, toads, and several kinds of lizards; among our serpents are the viper, which alone is venomous, the ringed snake and the blind worm, all of which, together with other species, are enumerated and described in their proper places. Our edible sea-fish are very numerous; among which we may reckon the turbot, dorie, seal, cod, plaise, smelt, mullet, &c. Herrings and mackarel extend to most parts of the kingdom; but pilchards are restricted to the coasts of Cornwall. The whale seldom appears on the English coast, nor the dolphin; but the porpoise is not uncommon. Our principal river fish comprehend the salmon and trout. The lobster is found on most of the rocky coasts, particularly of Scarborough. The crawfish, muscle and oysters, are abundant. The flora of Britain contains as great a variety of genera and species as any other country of equal extent; and those that are most worthy of notice, on account either of their variety or utility, or other peculiar circumstances attending them, are enumerated and described under their proper heads. Our native fruits are few, but others have been introduced and our own improved, so that plumbs, cherries, peaches, nectarines, apricots, figs, grapes, &c. are by the skill and care of the English gardeners raised in the greatest plenty and variety. The oak and beech are natives of England: the elm is probably an exotic; but there are few plants in any part of the known world, which have not been introduced into our plantations, nurseries, green-houses, and hot-houses.

The constitution of England is a limited monarchy counterpoised by two senates, one of hereditary peers, the other of representatives chosen by the people. (See CONSTITUTION, CROWN, KING, COMMONS, PEERS, PARLIAMENT.) For an account of the judicature of England, we refer to the articles JUDGE, JURY, COURT, CIRCUIT, JUSTICE, SHERIFF, &c. The established religion of England is that of the reformed church under the administration of the king, as supreme head, archbishops, bishops, deans, archdeacons, rectors, vicars, curates, &c. See each of these titles. See also CHURCH, CLERGY, CONVOCATION, Ecclesiastical COURTS, &c. Besides those who are members of the established church, England abounds with dissidents or dissenters of various descriptions. See these terms, and also INDEPENDENTS, PRESBYTERIANS, BAPTISTS, QUAKERS, METHODISTS, PAPISTS, &c. For the army and navy of England; its manufactures and commerce; its land and revenue; its population; and various other particulars; see BRITAIN, and the appropriate articles in this work.

ENGLAND, *history of*. The principal events belonging to the history of our country will be found under the names of the several kings who have reigned over it. To the articles attached to those names we might refer generally for a compressed detail of all the changes and revolutions to which England has, at its several periods, been subject; but in conformity to the plan sketched out in the article BRITAIN, we must in this place give a very brief outline of the history of England, from the Norman conquest to the accession of James I.; and likewise the history from that period to the present times. After the conquest, our history is represented

in so clear a light, as leaves little either obscure or uncertain. The only difficulty we shall find will be in condensing into a small space the leading facts that are not immediately connected with the lives of the sovereigns.

The Saxon monarchy (see SAXONS) had continued for more than six hundred years: during which, as we shall hereafter see, they enforced many of their own laws and customs, though they readily adopted others congenial to the country; and which were derived, as well from the Romans, as the ancient Britons, and which they found in the island upon their invasion of it. The habits and manners of this race were melted down and amalgamated with those of Norman institutions. Every thing was changed; the laws in some respects were improved, but there was still little taste for literature and science. From this period, however, we are to date the commencement of certain institutions which, though they required centuries to ripen into maturity, have nevertheless given this country a superiority over every other in the civilized world. The variety of dispositions of several foreign countries being imported into our island, at length blended into one national character, celebrated for its courage, its love of freedom, and its pride.

Immediately after the victory of Hastings, the conqueror marched towards London, carrying before him a standard which had been blessed by the pope; and to this the clergy, as is usual, hastily resorted. The bishops and magistrates came out to meet him, and offered him the crown, which he had won by his intrigues and valour. They stipulated terms to which he readily acceded, being desirous of a sovereignty by the free choice of the people rather than as claimed by the power of the sword. Though he knew himself to be their conqueror, he desired to be thought their lawful king. William felt that he had power to enforce obedience, but affecting the voice of the people, they imputed his elevation to their own generosity; and when they felt themselves oppressed or aggrieved, did not scruple to resist his power by open revolt and insurrection. The English hated the Normans, and were jealous of the power which they sustained in the new government; they envied the wealth which went to enrich those who were truly denominated adventurers in a foreign land, and which was raised by loading the natives with heavy taxes, that in those times were with difficulty sustained. At length William saw he must act with energy if he meant to reign, and from this time he seems to have regarded England rather as a conquest, than a justly acquired dominion. He deprived the bishops of all judgment in civil causes, a right which they had assumed during the Saxon succession. He restrained the clergy to the exercise of their ecclesiastical power, and he endeavoured to abolish trials by ordeal and camp fight. See CAMP-FIGHT, and ORDEAL.

We do not intend to recount the acts of the kings of England in this article, but shall rather give a general sketch of the changes and revolutions in the constitution, government, manners, &c. of England. The changes introduced by the Norman conquest were not very material to the interests of the people. Those who occupied the lowest ranks, still continued in a state of slavery; and their numbers were rather increased than diminished. The conquerors treated their slaves with so much severity, that a contemporary writer declined to give a description of it, lest its inhuman cruelty should appear incredible to posterity. As the children of slaves were also slaves, this order of the people would have increased exceedingly; if many of them had not from time to time obtained their freedom, either by fidelity, or uncommon acts of diligence. In some cases the clergy had the power of granting freedom to slaves, and sometimes

the office was performed voluntarily by penitents, who hoped thereby to obtain the pardon of their sins. The middle ranks in society, that filled up the interval between the freedmen and the barons, were composed of different bodies of men, from whom, in process of time, the yeomanry and many of the gentry of England are descended. The inhabitants of towns and cities were generally of this middle rank. The barons were a numerous, opulent, and powerful body of men, and comprehended all the considerable proprietors of land in England. The accession of the Normans produced many important changes in the political circumstances of the people—in the tenures by which they held their lands—the services to which they were subjected—the magistrates by whom they were governed—the courts in which they were judged,—and the laws they were obliged to obey. These changes were chiefly owing to the establishment of the *feudal system* (which see) of police and government in England, by William, in the same state of maturity to which it had then attained in his dominions on the continent.

As the most important changes in the English constitution were made either in the reign of John, by the limitation of the severities of that system, it will not be necessary to dwell on the intermediate reigns. The succession of the crown of England, after the death of Edward the Confessor, became so unsettled, that it seemed to be the object of ambition to every bold invader, who possessed the slightest pretence, together with power and courage, to seize the glittering prize. The second William, Henry, and Stephen, are regarded as usurpers, and did, at the time, reign with a disputed title. This was a fortunate circumstance to the natives and their posterity, as it contributed not a little to raise them from that insignificance into which they had been depressed, to the preservation of what was left, and to the restoration of what had been lost of their ancient liberties. For the Norman barons, having estates both in Normandy and England, were anxious that the ducal and royal crown should rest on the same head, that they might enjoy their estates in both countries. Many of these barons therefore favoured the pretensions of Robert duke of Normandy, eldest son of William I., to the crown of England. This obliged his opponents William and Henry to have recourse to the native English, who were still formidable by their numbers, after all the losses which they had sustained. Hence they felt their own importance in the scale of being, and obtained for themselves certain rights and immunities which their sovereigns were ill disposed to grant of their own free will. Henry I. granted them a charter, which proved a model on which the famous charter of liberties in the reign of John was formed. He also promulgated a system of laws consisting chiefly of those of Edward the Confessor. Stephen, as his title to the throne was more disputed, was more liberal of his promises; but as he was less disposed to perform what he had bound himself to do, his whole reign was a scene of contention and civil war. At this period the civil law was brought into England from Rome, but not without considerable opposition on the part of the people, who were so much enraged against it, that whenever they met with a copy of the Roman law, they destroyed it with every mark of indignation. Henry II. conciliated the affections of his subjects by granting them a charter, confirming that of his grandfather Henry I. To this prince, whose reign was protracted to a great length, the country was indebted for many improvements in the law, as well in its administration, as in the forms and practice of the courts. At this period the clergy, who were screened from punishment on account of their profession, committed every species of crime, which

led (A. D. 1164,) to the enactment of the celebrated constitutions which had the effect of reducing the clergy to the rank of subjects. Still, however, justice was not always administered in those ancient times with wisdom and impartiality, partly owing to the ignorance of the judges, and partly to the prevalence of faction among the suitors of the courts. Nor was it an easy matter to procure relief from an iniquitous sentence pronounced by a baron or sheriff, on account of the great distance and unsettled state of the king's court, which constantly attended his person. To remedy this inconvenience Henry II. with the advice of a great council of his prelates, earls and barons, at Northampton, A. D. 1176, divided the whole kingdom into six circuits, and appointed three judges to hold courts in each of these, by a commission from the king, empowering them to hear and determine all causes not exceeding the value of one half of a knight's fee, unless the matter was of such importance or difficulty as to require the judgment of the king's court in the royal presence. These itinerant justices took an oath to administer justice to all persons with impartiality. They had also authority to judge in all criminal causes and pleas of the crown, and to transact a variety of other affairs for the public good. Under the reign of Richard, besides laws relating to the voyage of his fleet to the Holy Land, and those connected with commerce, were others of an excellent nature, in which he attempted to establish an uniformity of weights and measures over the whole kingdom, a thing greatly wanted, but which has not even yet been accomplished. The changes introduced by John have been recited under the article CONSTITUTION. The barons, who procured the famous charter, have been viewed as acting in two capacities, 1, as military vassals of the crown: 2, as subjects of the kingdom. They consulted their own interest in the first capacity, by the limitations of the rigours of the feudal tenures which they procured, and in which all who held lands by military services shared with them. They consulted their interest in the second capacity, by the amendments which they procured in the general police of the kingdom, in which all their fellow subjects were partakers. These amendments tended to remove or alleviate the several grievances of which the people in general complained; of these, the greatest and most important was, that the mere will and command of the sovereign were substituted in the place of law, and men were seized, imprisoned, stripped of their estates, outlawed, banished, and even destroyed, without the form of trial. Next to the substitution of arbitrary will in place of law, was the king's personal interference in law-suits depending before his courts, in order to interrupt or pervert the regular course of justice. These flagrant outrages at length wrought their own cure, and those who had tyrannized over the people were obliged to submit to their power.

The common, as well as the statute law of England, received considerable improvements in the reign of Henry III.; but his successor Edward I. was, as a general and legislator, equalled by few of the kings of England, and surpassed by none. He was satisfied with a moderate degree of power, and only laboured to render himself terrible to his enemies. The English, now incorporated with their fierce Norman conquerors, were no longer the tame consenting people they formerly appeared, but were always prepared to reason with that authority which could not easily be resisted. This spirit of opposition was tinged with cruelty: regardless of their own lives, the people did not seem very solicitous about the lives of others. Penal laws began to assume more rigour: in the times of William the Conqueror, it was a law, that no man should be punished with death; in the

the reign of Edward, that law was entirely laid aside, and several crimes were rendered capital. But what gave permanence to the reputation of this monarch, was the degree of power the people began to assume during this period. The clergy and barons he regarded as rivals; and to weaken their force, he gave authority to the commons: a law was enacted, by which no tax could be levied without their consent. On account of the many wise laws made in this reign, the monarch has been styled the English Justinian. Some of these statutes respected the church, and were intended to fet bounds to the power of the pope, the riches of the clergy, and the encroachments of the spiritual courts. Others were calculated for explaining, confirming, and enlarging the liberties which had been granted by the great charter. According to sir Matthew Hale, "the model of the common law, especially in relation to the administration of common justice between party and party, as it was rectified by this king, so in a great measure it has continued the same in all succeeding ages to this day; so that the mark or epocha we are to take for the true dating of the law of England, what it is, is to be considered, stated, and estimated, from what it was when this king left it. Before his time it was in a great measure rude and unpolished, in comparison of what it was thus polished and ordered by him, so hath it stood hitherto, without any great or considerable alteration." Edward made great efforts to reduce the whole island of Britain into one kingdom, governed by the same sovereign, and subject to the same laws; and with respect to Wales, he completely succeeded so as to introduce into it many of the English laws, customs, courts, and magistrates. His efforts to unite Scotland with England finally failed, and they served only to kindle a most violent and implacable animosity between the people of these two kingdoms, which gradually rendered their manners, laws, and customs more dissimilar than they had been in more ancient and amicable times. In the following reign, the Scots gained a complete victory over the greatest army ever sent into their country: but Edward III., the next in order of succession, contested, with Philip de Valois, his right to the kingdom of France. He therefore made an expedition into that country, and in the celebrated battles of Cressly and Poictiers, entirely destroyed the French army, and carried the monarch captive to England. See EDWARD III.

This wise prince never neglected to consult his parliament in affairs of moment. There are still extant his writs of summons to no fewer than seventy parliaments and great councils. The distinction between these assemblies was this; when he desired only the advice and assistance of his great barons who still possessed the greatest part of the power and property of the kingdom, he called the great council, consisting of all the great men, both of the clergy and laity, who held of the crown by barony, and were entitled to a particular summons. When he stood in need of the counsel and aid of all his subjects, he called a full parliament, which consisted not only of the barons spiritual and temporal, but also of the representatives of the inferior clergy,—of the smaller barons, or freeholders,—and of the citizens and burghesses of the kingdom; and those representatives of the clergy and laity, below the rank of barons, were called the spiritual and temporal commons.

Richard II. came to the crown a minor, and by his heroism in crushing the rebellion of Wat Tyler excited considerable expectation, which was completely disappointed by all the subsequent acts of his life. He submitted himself to evil counsellors, who took possession of his mind, and by their advice he sacrificed his best and ablest friends, and endeavoured to render himself despotic. But he was over-

powered, subdued, and obliged to resign his crown in favour of his cousin Henry duke of Lancaster; and this was the commencement of those contests between the houses of York and Lancaster, which for several years after deluged the kingdom with blood, and which nevertheless contributed in no small degree to give strength and consistency to the constitution. In the reign of Richard, Wickliffe began the great work of reformation. The deposed monarch was murdered with a pole-ax in Pontefract castle in the 34th year of his age, having reigned 22 years. His successor, Henry IV. surnamed Bolingbroke, had to contend with much internal trouble, and had so little claim to the sovereignty which he assumed, that conspiracies were speedily formed against him; these, however, were quelled and the leaders of them were executed. "If," says a good writer, "we compare the times at this period of our history with those of king John, or those of some reigns before him, we shall find a great change with respect to the insurgent barons. In the former period they made frequent insurrections, were often taken in open rebellion, and as frequently pardoned: but in this period they were seldom taken without suffering the utmost rigour of the law. This plainly shews how much the power of the barons was sunk in the course of a couple of centuries. This revolution of power is, notwithstanding, natural and obvious: as the people began to share the government with the nobles, the king was fixed upon as a third person to secure the balance, and both were contented to make him great from a jealousy of each other. Noblemen were therefore now executed, not as petty monarchs, but offending subjects, and none but kings were considered as exempt from penal laws."

In this reign the suppression of one rebellion seemed only to make way for another more formidable than the former, and more extensive in its consequences. The calamities of this period were not, however, confined to internal factions excited by discontented barons: the country was threatened with foreign invasions, and the clergy added not a little to the disturbance of the public peace. Ever since Wickliffe had published his opinions, his doctrine had been gaining ground, and the clergy were in dread of its prevailing to the exclusion of their system and to the ruin of their emoluments. Henry joined the clergy, considering that they might be made a powerful engine in establishing his usurped throne, and he recommended the parliament to the care of the church. At first the house of commons seemed reluctant in drawing the sword of persecution; they had not, however, vigour sufficient to oppose the power of the court and the clamours of the priests, but became instruments in their hands for the perpetration of much mischief. An act was passed for burning obstinate heretics; and William Sawfre, a follower of Wickliffe, was, by virtue of the king's writ, delivered to the mayor of London, and burned alive. This was the first martyr in England, on account of religion; but the fires, being once lighted, were not suffered to be extinguished. The clergy, under a mask of hypocrisy, and pretending a regard to truth, took every means that cruelty could suggest of establishing that degree of temporal power, which they had possessed three centuries before. They succeeded, but with this striking difference, that, as in the times of the Saxon heptarchy, their power was founded in the love of the people, in the present case it had its origin in, and was wholly maintained by, their fears. By these means, Henry surmounted all his troubles, and the kingdom enjoyed tranquillity. Towards the close of life he determined to embark upon an expedition to Jerusalem, as well to expiate, as he imagined, the sins of former years, as to induce his maker to protract the term of his life. His

increasing infirmities prevented him from executing his plan; and in his 46th year he resigned, by death, his crown to his son Henry V. During this reign, if allowance be made for the rancour of the priests, to whom the king was too subservient, the government may be said to have assumed a form and liberty; the distinction between the nobility and the people was rendered less considerable, and the magistrates were less arbitrary and less venal.

Henry V. was the great hero of his age, and the courage which he had manifested from his earliest years laid claim to the esteem and affection of the people over whom he was destined to reign. At this period, courage in the great was regarded as almost the only virtue: courage and superstition then made up the whole system of human duty. The clergy, notwithstanding their revenues, paid very little attention to the morals of the people, and were, if possible, less solicitous about their own character: the vices in which they openly indulged, and the passions to which they gave free reins, drew upon them a just degree of contempt; of which they avenged themselves, by having recourse to the engine of persecution. In this they were encouraged by the king, who, by not opposing, may be regarded as a participator of their crimes. One of the early acts of this reign was an attempt to suppress the doctrines of Wickliffe; and John Oldcastle, baron Cobham, was the principal sufferer in their defence. This excellent man was doomed to bear the most excruciating torments: he was hung up by the middle with a chain, and by a slow fire literally roasted alive. The deed was scarcely perpetrated when the king, probably disgusted with the cruelty that had been perpetrated by his sanction and authority, resolved to take advantage of the troubles existing in France to make a conquest of that country. Thither he led a very large army, with which he defeated and almost wholly destroyed one six times larger than his own: he immediately advanced into the heart of the country, making himself master of many towns. At length he married Catherine, daughter of the French king, and acquired thereby the administration of affairs in that kingdom, during the life of his father-in-law, fully expecting to be appointed his successor. But his death, in the year 1422, frustrated his own and the nation's hopes. His son, an infant, was afterwards declared king of France and England; but, possessing none of his father's heroism, he soon lost in France all that Henry V. had acquired. The triumphs in France produced scarcely any advantages at home. As the English grew more warlike, they became more brutal; and in their eagerness after foreign possessions, they neglected the cultivation and improvement of those at home. The language became more barbarous. Chaucer and others, about a century before, seemed to have drawn it from obscurity, and enriched it with new terms and combinations; but at this period it relapsed into its former grossness.

The reign of Henry VI. witnessed much bloodshed, owing to the rival families of York and Lancaster. These calamities did not subside till the reign of Henry VII., who was himself of the house of Lancaster, and married the daughter of Edward IV. of the house of York, when an end was put to the dissensions between the different factions of the white and red rose. In the famous battle that fixed Edward IV. on the throne of England, it is said that 40,000 men were left dead in the field. In this dreadful contest, each party, as it happened to be victorious, called in the executioner to complete the bloody tragedy begun in the field. In the reign of Henry VI. the art of printing was first practised in England by William Caxton. He translated some French works, which he printed; and, by

his new art, gave currency and celebrity to the translations of others. The priests at this period possessed no small share of erudition, as is evident from some Latin productions still extant; but learning was separated from the purposes of common life, and though not neglected by the clergy, yet it descended no lower, the people at large not considering it as any concern of theirs.

The wars in which Edward IV. engaged were long and bloody; and, upon a suspension of arms at home, he proclaimed war with France, which he knew would gratify his subjects, who have been, at almost every period of their history, more fond of splendid than useful acquisitions. To prosecute this scheme, he sent to his ally, the duke of Burgundy, a reinforcement of 8000 men; and soon after followed himself, at the head of a very numerous army. The French king was alarmed at this formidable invasion, and feeling that he was unable to contend with his antagonist, he had recourse to treaty; and for a stipulated sum, Edward agreed to lead back his forces to England. Towards the close of life he indulged the hope of invading France again: his parliament consented, and in that assembly of the nation the project was unanimously declared to be just and necessary. The people seemed pleased with the prospect, and great preparations were made for the expedition, when, fortunately for the interests of humanity, Edward died after a reign of little more than 22 years.

Edward V. succeeded, as we have seen, (see EDWARD,) to the kingdom in name, but not in fact: for, long before he was capable of acting for himself, he was deposed and murdered at the instigation of his uncle, the duke of Gloucester, who secured to himself the crown under the title of Richard III. The infamy of this prince's character has been fully described by every historian of authority. As he obtained the government by treachery and murder, so he lost his life in support of what he had unlawfully gained. At the battle of Bosworth Richard had to contend with Henry, earl of Richmond, who was not only completely victorious, but was proclaimed king by the unanimous voice of the army, on the very spot in which the cruel Richard was slain. By the death of this king, the Plantagenet race, which had been in possession of the throne more than 300 years, became extinct. With him also terminated the contests between the houses of York and Lancaster, in which, in the course of about 30 years, an hundred thousand lives were lost either in battle or by the hands of the executioner. These dissensions had reduced the kingdom to a state of almost savage barbarity: laws, arts, and commerce were entirely neglected; every thing laudable gave place to the practice of arms. The people had attained no ideas of pacific government, nor could they applaud or justify those who cultivated it. In their wars, it is recorded to their credit, that the women, however formidable and active, were exempted from capital punishment, unless accused of the undefined and undefinable crime of witchcraft. The clergy were distinct from the laity in customs, constitutions, and learning: they were governed by the common law, which was delivered to them by the traditions of their ancestors. As a body, they did not interest themselves in the civil polity; and were not displeased to see the laity, whom they did not deign to regard as fellow-subjects, but rivals for power, weakening themselves by continual contests: the laity, on the other hand, regarded the clergy with blind veneration, which lessened their respect and attachment to the monarch on the throne. There was little virtue among individuals of the nation, and the government was subject to disorders of the most fatal kind, which perpetually produced all the horrors of civil war.

With

## ENGLAND.

With the reign of Henry VII. we commence a new era in the history of our country. Under his sway we behold one of the greatest revolutions that was ever effected by the prudence and perseverance of one great prince: a nation of tumult reduced to civil subordination; a haughty aristocracy humbled; wise laws enacted; commerce restored; and the arts of peace cultivated and encouraged by a people, to whom before, war, only was delightful. The whole government put on a new form, and Henry was one of the most useful monarchs that ever held the sceptre of these kingdoms. —

The first care of Henry was to unite the interests of the houses of Lancaster and York, by marrying Elizabeth, the daughter of Edward IV. His reign began very auspiciously by a strict obedience to the laws, which he ever after enforced with firmness and dignity. Before his reign it had been usual to take away the lives of those attainted of treason; but Henry thought it sufficient, in most cases, to deprive those taken in arms of their fortune and estates, which he applied to his own use. By these means he deprived his enemies of the power of injuring him; and he was enabled, by new accessions of wealth, to perform many acts of liberality. He is said to have released all prisoners for debt in his dominions, whose debts did not amount to forty shillings, and paid the creditors their whole demand from his own coffers. He has been accused of avarice, but it is doubtful whether his conduct in this respect does not rather merit the applause of useful economy. His government was disturbed by attempts at setting on the throne Lambert Simnel, as earl of Warwick; and afterwards by a similar attempt with regard to Perkin Warbeck. In the year 1499 he freed himself from these conspiracies, by the conviction and execution of Perkin and the feigned earl of Warwick. After this, the reign of Henry was truly respectable: his government was formidable to his own subjects, and claimed the respect of rival potentates. He paid much attention to the wants of the lower classes, and was anxious to depress in the scale of power the nobility and clergy. From these most of the calamities of former reigns had resulted; and on that account he contrived means to lessen their authority in the state. He allowed the nobility, by a law passed in his reign, to alienate their estates; and he diminished, as far as he was able, the privileges claimed by the clergy as their right. He was, at the same time, a friend to the people, who in former periods were the sure victims of powerful ambition and revenge. They, in all cases, were the sufferers, on whatever side they fought, if they had the misfortune to lose the victory. To remedy this, in a great degree, Henry procured the passing of an act, by which it was established that no person should be impeached or attainted for assisting the king for the time being. This wise statute served to repress the desire of civil war, as multitudes would naturally take arms in defence of that side on which they were sure of losing nothing by defeat, and their numbers would intimidate insurgents. But the greatest efforts of this king were directed to promote trade and commerce, which naturally introduced a spirit of liberty among the people, and disengaged them from their dependence on the nobility. Before this era, the towns owed their original to some strong castle in the neighbourhood, where the great lord generally resided, maintaining at his expence a very large retinue, who, as dependents on his bounty, were on all occasions bound to vindicate his cause. The number of these drew together, in or near the same place, artificers, victuallers, and shop-keepers, to furnish the lord and his attendants with the necessaries of which they stood in need. It was the wise policy of Henry to

bring the towns from such a neighbourhood, by inviting the inhabitants to a more commercial situation. He attempted to teach them frugality and the payment of debts; the life of industry, by his own example; and never omitted to include the rights and principles of commerce, in all his treaties with foreign princes.

At this period the continent, as well as the British isles, seemed to be making great advances to improvement. The sovereigns of Sweden, France, and Spain, were the encouragers and protectors of the rising arts. The Portuguese had sailed round the Cape of Good Hope, and Columbus had just made the discovery of a new world. Henry was desirous of following the example set him, and granted to certain enterprising merchants to go in quest of new countries. By these and similar exertions the king saw his country civilized, the people pay their taxes without insurrection; the nobility learning a just subordination, the laws alone suffered to inflict punishment, towns begun to separate from the castles of the nobility; commerce every day increased, and the spirit of faction was in a great measure extinguished. He was at peace with all the world, and having issued a general pardon to his own subjects, he had reason to expect the happiness to which wise measures and true patriotism are justly entitled; when, at the age of 52, he died of the gout in his stomach. In some respects he has been regarded as the second Alfred, a title to which he has a good claim, on account of the great changes which he introduced in his kingdom;—changes which had the most favourable tendency to effect the improvement and happiness of his subjects.

Henry VIII., the son to the late king, assumed the reins of power under the most fortunate auspices. He found himself in possession of a peaceable and flourishing kingdom; prudent ministers, who knew the wants of the people, and were ready to provide for them; and a well-stored treasury. The young king, however, made but an ill use of the bounties of providence, with which he was so abundantly surrounded. He had been diligently instructed in all the learning of the times; but his stock of knowledge served only to inflame his pride, and not to control his vicious affections. The love of his subjects was testified by an adulation, which produced the most mischievous effects. His vast wealth, instead of relieving his subjects, or of increasing the national honour, only contributed to supply his debaucheries, or gratify the rapacity of the ministers of his pleasure. The acts of his life will come more properly under the article devoted to his name. In this place it will be sufficient to observe, that he was perpetually falling from one extreme to another, and agitated by contrary passions; it became doubtful to his subjects in what manner they should act, or what they should believe, so as to obtain his approbation. His conduct as a king was marked with the most atrocious acts of tyranny; he expected every one to submit to his will, however frequently that will was changed: yet his reign is memorable on account of the great revolution that was achieved in it by the celebrated Luther, for a full account of which we refer to the article LUTHER. At first the king wrote against the doctrines avowed by the former; and for his ability and learning, obtained from the pope the title of “Defender of the Faith,” a title which has been continued to his successors to the present time. He afterwards revolted from the Roman church, and required that his subjects should acknowledge him, and him only as head of the church of England. The parliament, entirely dependent on the king, sided with him in his views of separating from the church of Rome, and readily complied with his other measures to strengthen

the reformation. Henry, who was an artful politician, knowing that his parliament was devoted to his will, made use of the opportunity to render himself absolute. He accordingly opposed the parliament against the monks, and obtained their suppression. While parliament was busy in suppressing the religious houses, most of which were houses of infamy, the king was devising methods of destroying the power of the suppressors. This was the origin of the unlimited power which he now assumed: he had a most complying parliament, ready to sanction not only what he did, which in many instances were deeds of the darkest hue, but likewise what he intended to do. He was not wanting to strengthen his own power, and claimed the same obedience to his proclamation as to the acts of the whole legislature. No king of England, as will be seen hereafter, lived so much the terror of his people. Some persons wielding a sceptre have been tyrants, from the frequent revolt of their subjects; some, from being misled by favourites; and some, from a spirit of party: but Henry VIII. was cruel, from a disposition which seemed prone to inflict misery on all about him; he was a savage in government, in religion, and in his own family: yet such are the inscrutable dispensations of heaven, that while the harmless Henry VI. was dethroned, imprisoned, and assassinated, the present tyrant was permitted to die a peaceable and natural death, if we except the sufferings which a guilty conscience cannot fail to inflict. Fortunately perhaps for the people, Henry contrived to dissipate all those treasures of which his tyranny plundered his subjects: he died poor, and transmitted the crown to his son and successor as dependent on the people for their supplies in parliament as at any former period. The wanton profusion of princes is always hurtful to themselves; but in many instances it has been beneficial to their subjects, by preventing greater evils. If Henry VIII. had been more frugal, he would probably have been more dangerous.

The character of Edward VI. has, under his own name, been described. He died at too early an age to act for himself; but during his short reign, the principles of the reformation were encouraged; people were allowed to use or disuse the practice of confession, as they thought fit; images were taken from the churches, priests were allowed to marry, the mass was abolished, and a liturgy was drawn up, which, with very few alterations, has been continued to the present times. Such important changes could not be effected without danger: insurrections were excited in many parts of the kingdom, which were without much difficulty suppressed, though many were the victims of the unhappy contests.

The reign of queen Mary was marked with cruelty and bloodshed. She restored the Roman Catholic religion, and without hesitation burnt, or otherwise destroyed, all who fearlessly opposed her will, and the will of her infamous ministers, Bonner and Gardiner. The reign of this sovereign was fortunately short; yet, in somewhat less than four years, five eminent and conscientious prelates, twenty-one ministers, and more than eight hundred subjects of lower rank in life, were consigned to the flames for maintaining what they believed to be truth: besides these, we have no accurate account of the numbers who died in prison, by more lingering and more cruel deaths than even the flames of Smithfield could inflict; nor has it been recorded how many, through fear of death, sacrificed a good conscience, and thereby endured for the remainder of their lives sufferings a thousand times worse than the death which a tyrant is enabled to order.

Elizabeth, whose character and government have been delineated in the last volume, restored the principles of the

reformation, and advanced the kingdom to the highest pitch of splendour. She had been nurtured in the school of adversity, and drew from it lessons of the highest importance to her future conduct. While secluded from the busy world in a lonesome prison, she was employed in the improvement of her mind; and in devising methods of reforming the church, so soon as providence should make way for her government; and one of her earliest acts as sovereign was to establish the reformed religion. The people readily seconded her designs: they perceived the ill use which the papists had made of their power in the last reign; and they were willing to suppose that the savage acts, which had been committed by Mary and her bishops, were the necessary consequences of the faith which they espoused, and in behalf of which they effected their cruel purposes. Elizabeth soon assembled her parliament, the reformation was finished, and that form of religion was established which is now deemed the religion of the country. The clergy, in general, subscribed to the new forms: of nearly ten thousand who were in possession of benefices of different degrees of rank and value, scarcely more than an hundred chose to quit the emoluments of their office, rather than abandon the principles to which they had adhered in the last reign. "Thus," says an historian, "England changed its belief four times since the accession of Henry VIII." Strange that a people, who are so resolute, should be guilty of so much inconsistency! that the same people, who this day publicly burn heretics, should the next not only think them guiltless, but conform to their opinions. Elizabeth, though firmly fixed on her throne, had enemies in almost all the neighbouring potentates; who endeavoured by every means in their power to excite discontent among her own Catholic subjects. In this situation, she could only rely upon the resources which proceeded from the affection of her subjects, and the wisdom of her administration. Her governing maxim was unquestionably founded in wisdom; it consisted in acquiring the esteem and affection of her people. She was an economist of the nation's money, and sparing in her rewards to her favourites. She distributed rewards and punishments with impartiality; knew when to flatter and when to upbraid; could dissemble submission and preserve her prerogatives; she studied the people she was to govern, and not unfrequently flattered their follies in order to secure their hearts.

The errors of this sovereign, and the acts of cruelty to which she gave her sanction, have been described in her own life, or in that of archbishop Cranmer, or will be found hereafter in the article Mary queen of Scots, or in other parts of this work of minor consideration; but it must be observed here, that whatever punishments or cruelties were exercised in this reign, they mostly fell upon the great, and in no instance were the people more happy internally, or more formidable abroad, than during this period. It will, however, be readily admitted, that it was not owing entirely to the queen that the nation was so completely prosperous at this period; the people, as if spontaneously, began to exert their native powers, and every art, and every genius put forth all their vigour. The English could not boast of new or splendid acquisitions: their influence in foreign courts was extremely limited, but commerce grew up and flourished. The people began to feel the effects of their own exertions, and to understand in what consisted the independency of a great nation; and England became at once laborious, enterprising, powerful, and in a degree polished and polite. The successful voyages of the Spaniards and Portuguese excited their emulation: they fitted out several expeditions with a view of discovering a northern passage to China, and, though

## ENGLAND.

though disappointed in their first and principal object, their voyages were not wholly fruitless. Our countrymen, Cavendish and sir Francis Drake, circumnavigated the globe, and discovered in the prosecution of their voyages a skill and prowess very superior to the most experienced navigators of those nations who led the way in nautical discovery. Sir Walter Raleigh, without any assistance from government, colonized New England; and these expeditions at length formed one of the most powerful marines of Europe, which in a very short time was enabled to oppose the fleet of Spain. (See ARMADA.) The superiority obtained by the English at sea, at this period, gave them a sort of naval sovereignty which they have ever since inviolably preserved, and which, we trust, they will very long maintain, notwithstanding the boastful language of the present emperor of France. If, for wise purposes, he must subject the continent to his power and controul, we trust that our own islands will, by union among the people, be freed from the tyranny which he has for many years been exercising among other nations, which have evidently been sacrificed by their own want of unanimity, and by the mismanagement of their sovereigns.

In the reign of Elizabeth, external commerce was not more cultivated than internal manufactures. Flemish manufacturers, who had been persecuted at home, fled to England for an asylum, which they found, and for which they made ample amends by the arts which they introduced, and the industry which was excited by their example, and by the wealth which their labours acquired. In polite arts and in literature the English excelled all other nations. The reign of Elizabeth has by some writers been denominated the Augustan age of literature. The disputes caused by the reformation of religion had retarded the progress of our language among the powerful, but they excited a spirit of enquiry among the middling and lower orders of society. The people began to read, and being allowed to peruse the bible in their own language, their morals, and perhaps their taste, rapidly improved. The reformers, who had fled from the persecutions of Mary, returned to promulgate their doctrines at home, and by a residence abroad their language was corrupted by foreign idioms and barbarous phrases. These archbishop Parker set himself assiduously to reform, as well by his own excellent example as by precept. He corrected the English translation of the bible, and printed it with royal magnificence. His own style possessed all the eloquence of the times; it was manly and concise, but wanted smoothness.

Such were the leading improvements in Elizabeth's reign; and, says a good writer, "if we look through history and consider the rise of kingdoms, we shall not find, in all its volumes, such an instance of a nation becoming wise, powerful, and happy in so short a time. The source of our felicity may be traced to the reign of Henry VII., and though the stream was interrupted by intervening tyrannies, yet, before the end of Elizabeth's life, who was his grand-daughter, the people became the most polished and the most happy people upon earth. Liberty, it is true, as yet continued to fluctuate: Elizabeth knew her own power, and often stretched it to the very limits of despotism; but when commerce was introduced, liberty necessarily entered in its train; for there never was a nation completely commercial, and at the same time perfectly despotic."

On the death of Elizabeth James VI. of Scotland succeeded to the throne of England, with the universal approbation of all orders of the state. Elizabeth bequeathed him her crown almost with her last breath; he was the nearest in the order of succession, and he had all the sanction which parliament could confer. He began his reign by a laudable

attempt to unite both kingdoms into one, which he effected without much difficulty, and from that period the two kingdoms have been governed by one sovereign. James, though used to arbitrary power, set himself to study the English laws, by the authority of which he resolved to govern. Whether he did not comprehend their full import, or that his habits were too much fixed to submit to the necessary changes which his new situation required, it would be useless to enquire; but it is certain that his whole reign was marked with disputes between him and his parliament. The king was ever attempting to keep the royal splendour unfulfilled; the other aiming at lessening the dangerous part of the prerogative: the one labouring to preserve the laws and institutions of former reigns; the other as steadfast in asserting the inherent privileges of mankind. When the parliament refused a subsidy, the king was desirous of availing himself of the precedents set by other monarchs, by extorting a benevolence. The house of commons felt their consequence as the protectors of the people, and remonstrated against every act of arbitrary power, as incompatible with their rights and privileges. These attempts of the crown, and the resistance of the people, continued through the whole reign, and first gave rise to that spirit of party which has ever subsisted in England, the one side declaring for the king's prerogative, the other for the rights and liberties of the subject.

James exhibited much moderation with regard to those who did not think on religious subjects as he was accustomed to think, and who did not conform to the established forms of church discipline, wisely judging that men should be punished for evil actions, and not for erroneous opinions. The conspirators against his government, as will be seen in his life, were severely punished; but he cultivated the arts of peace, and obtained as a just reward the general good will of the nation. It has been ascribed to this monarch that the English have attained to a noble freedom of thought, and the dignity of justifying their opinions. James neither cultivated nor understood foreign negotiations or alliances. His reign was marked with none of the splendours of triumph, nor with new conquests and acquired dominions; but the arts were silently advancing in improvement: reason was extending her influence, and desecrating a thousand errors in religion and government that had been rivetted by long prescription. The people began to think for themselves, to estimate their rights and consequence: the reformation had introduced a spirit of liberty, even at the time that the constitution and the laws were built upon arbitrary power. "James," says the historian, "taught them, by his own example, to argue upon these topics: he vindicated the divine right of kings against the natural privileges of the people: the subject began in the controversy, and it was soon discovered that the monarch's was the weakest side of the question."

Charles I. ascended the throne in the year 1625, and was extremely popular, as well on account of his own virtues and address, as in respect to the fortunate circumstances in which he was placed. The country was in a peaceable and flourishing state: his title to the crown was undisputed, and he had formed an alliance with one of the most powerful monarchs that ever reigned in France, whose sister he had married. The pleasing prospect was of short continuance; the people had learned to reason: they felt their own power, and it was determined in parliament to oppose the ancient claims of the crown. Charles had been taught to consider the royal privileges as sacred pledges, which it was his duty to defend: his father had implanted the doctrines of hereditary and indefeasible right early in his mind. James contemplated these

these doctrines in theory, but it was soon the fate of Charles to assert and defend them by action. He mistook the genius of the people he had to govern; they had imbibed the principles of liberty; but he wished to act by maxims and precedents that had their origin in times of ignorance and slavery. The late king had been forced into breach with Spain, and Charles gave early indications of a despotic temper, which rendered the parliament remiss in furnishing him with money for carrying on the war. In a short time his favourite Buckingham persuaded him to take the part of the French Hugonots, in their quarrel with the crown. They were ill supported, and the protestant interest received an irrecoverable blow in France. The blame was attributed by the people and parliament to Buckingham, who was assassinated by Felton. This the king laid seriously to heart, though it did not deter him from his arbitrary proceedings. For several years Charles reigned without assembling a parliament, during which he did as he pleased, promulgating laws, and imposing taxes on his subjects to the great mortification of those who felt for their liberties as men and Englishmen. He laid arbitrary impositions upon trade, which many resisted: he levied monies upon monopolies of salt, soap, and other necessaries of life. His government became every day more unpopular, and Burton and Pryne wrote against the proceedings of the court. They were prosecuted for their writings in the star-chamber in a very arbitrary and cruel manner, and punished with so much severity as excited an almost universal indignation against the authors of their sufferings. The king next made use of Laud and Strafford as instruments in carrying on his despotic measures. These he was in a short time obliged to abandon to an ignominious death on the scaffold. Charles, in the early part of his reign, had passed the petition of rights into a law, which was intended by parliament for the future security of the liberty of the subject, by which it was enacted "that no man hereafter should be compelled to make any gift, loan, benevolence, tax, &c. without common consent of parliament." This principle he perpetually violated till at length a civil war broke out. Notwithstanding the many acts of tyranny and oppression, of which the king and his ministers had been guilty, yet multitudes sided with the court and joined the standard of Charles. Many of the nobility and gentry were attached to the crown, and considered their own honours as connected with it, and no inconsiderable part of the landed interest joined the king. The parliament claimed for themselves the executive power, and were favoured by most of the trading towns and corporations; but its great resource lay in London. The first battle was fought at Edge-hill, in Warwickshire, in which the royalists were so far triumphant that parliament was obliged to invite the assistance of the Scots, who entered England with 20,000 horse and foot. From this period war was carried on with various success, till at length the king was overpowered, reduced, imprisoned, tried, and finally beheaded. The character of this prince will be found under the article CHARLES I. With the death of the king, the miseries of civil war terminated, and the parliament, which was triumphant, had now no enemy to fear, except those very troops which hitherto had been instruments in their hands, in achieving their designs. At first they hoped to disband the troops; but Cromwell, who was the rival power in the state, had other projects to accomplish. He had already rendered the army in a great measure independent of the parliament; and now formed a council of officers, and another of common soldiers, called agitators, who were appointed to enquire into the grievances of the military, and lay them before parliament. As the commons, from neces-

sity, granted their requests, the army rose in their demand, till at length the parliament enjoyed but the shadow of authority. It, however, passed an act, making it high treason to acknowledge Charles Stewart, son of the deceased king, as successor to the throne. They likewise voted the house of lords useless and dangerous, and passed an act for the abolition of all kingly power. A great seal was made, on one side of which were engraved the arms of England and Ireland, and on the reverse was represented the house of commons sitting, with the motto, "The first year of freedom, by God's blessing restored 1648." No measure was omitted that could probably establish the power of the usurper, and exclude for ever the kingly power in England. Much was done for retrieving the glory of England at sea. Cromwell and Ireton excited the jealousy of the republicans, who contrived first to employ them in the reduction of Ireland, and afterwards against the Scots, who had acknowledged and received Charles II. as their king. Almost immediately, by the most unparalleled exertions, a fleet was produced superior to any that had ever been seen in Europe. An act of navigation was passed, and war was declared against the Dutch, who were till then regarded as invincible at sea. Cromwell, from his successes in Scotland, found little difficulty in obtaining the honour of being declared commander in chief of the English army. Admiral Blake, and other naval commanders, carried the terror of the English name by sea to all quarters of the globe, and Cromwell, having little employment, began to think how he might establish his own authority paramount to that of the state. On the 20th of April 1653, at the head of 300 musqueteers, he dissolved the parliament, opprobriously driving the members, about one hundred in number, out of their house. He next annihilated the council of state, with which the executive power was lodged, and transferred the administration of government to about 140 persons, whom he summoned to Whitehall on the 4th of July 1653. After this he was declared lord protector; which, however, did not comport with his ambitious views; he was desirous of the name; as well as the power of king, to which he could never arrive; and in September 1658, he died after an usurpation of nearly five years. See CROMWELL.

From Charles's death in 1648, to the decease of Cromwell in 1658, England was unquestionably improved equally in riches and power; besides the introduction of the navigation act, which was established in the reign of Charles II. and which has been regarded as the palladium of English trade; monopolies of all kinds were abolished, and liberty of conscience to all sects was granted, which was highly advantageous to the population and manufactures of the country. Under Cromwell, the arts, sciences, and literature were not much encouraged, yet he did many things worthy of praise; and as his genius and capacity led him to the choice of fit persons for the several parts of administration, so he paid some regard to men of learning, and particularly to those entrusted with the care of youth at the universities. Richard, his successor, possessed none of the talents for business, nor indeed any activity of disposition, for which his late brother was so celebrated, and was in a very short time driven, without resistance, into that obscurity for which his temper was better adapted, than for the business of government. The resignation of his power made way for

Charles II. who returned to the throne of his father by the general concurrence of the people; this was in the year 1660, and for some time he seemed desirous of promoting the people's happiness, though he did not forget to avenge himself on the enemies of the late king; the bodies of Cromwell, Ireton, and Bradshaw were taken from the tomb,

and treated with every indignity. Of those who sat in judgment on Charles I. some were dead, others had left the country, and some the reigning prince thought deserving of mercy, but ten were devoted to almost immediate destruction. These bore their sufferings with the constancy of martyrs dying in a good cause, thanking heaven in the extreme of their torments, that they were allowed to be witnesses of the truth. It was now to be feared that the tide of loyalty would bear away in its course all the former moulds of freedom. Parliament seemed to concur in all the designs of the court, and even to anticipate its wishes; but the monarch was by no means attentive to those who had followed him in his misfortunes; his pleasures and his flatteries engrossed all his cares, and exhausted his finances, so that he had nothing left, and, apparently, no wish to pay the debt of gratitude. From those who would willingly have expostulated with him on his misconduct, he fled, and endeavoured to forget every kind of serious business in scenes of mirth, riot, and debauchery. By his own example, he undermined the principles of religion, and the nation, prone to extremes, exhibited every species of licentiousness, which was practised in the most dissolute court that ever existed in England. Charles II. though without a pretence to religion, permitted the persecution of sectaries, which excited among those, who were objects of it, a plan for a general insurrection. The plot was discovered, and the conspirators were taken and executed. This circumstance afforded a pretext for continuing the parliament then sitting; and repealing the act for triennial parliaments, as being dangerous in times of commotion. This parliament was so completely subservient to the will of the king, that he might, with activity, have become absolute. They confirmed the infamous doctrine of passive obedience by a solemn act, and assigned the king a revenue of twelve hundred thousand pounds, a sum which none of his predecessors had ever possessed; nevertheless his prodigality rendered him indigent, and instead of desiring an ascendancy over his parliament, he was content to be a perpetual dependent on their bounty. His prodigality and libertinism soon alienated the affections of his subjects, which in the short period of two years were changed to a contempt of his person and administration. The war, in which he engaged with the Dutch, was unattended with any brilliant success, and the enemy's attempting to sail up the river Thames excited clamours against the government. The people began to compare the present state of things with the measures and administration of Cromwell; in the one case they enjoyed security at home, and claimed the highest respect from surrounding nations; in the other every principle, private and public, was forced to give way to the passions of the sovereign, which he was determined to gratify at any expence. Uniformity in religion became the popular cry, and, in 1673, the test act was passed, obliging every person in or under government, not only to take the oaths of allegiance and supremacy, but receive the sacrament of the Lord's-supper in some parish church, before competent witnesses, and subscribe a declaration renouncing the doctrine of transubstantiation. This was levelled against the duke of York, the king's brother, who was an avowed papist, and whom the parliament wished to exclude from the throne. The fears and discontents of the nation were vented without restraint, which gave great offence to the court. A great degree of severity was exercised against the nonconformists to episcopacy, and every means taken that was likely to repress the rising spirit of the country. It was known or violently suspected that Charles was a pensioner on the court of France, his parliament in 1677, addressed him to make war upon that country, which

he refused. The people became exasperated against almost all public measures; the king was alarmed with the prospect of a civil war, and made considerable concessions to avoid the odium which his past conduct had justly incurred. Many of the leading members of parliament had however determined on such a change as should exclude the duke of York from the crown. To forward this the famous plot of Titus Oates was contrived, which charged the papists with a design of murdering the king, and of introducing popery by means of the Jesuits, as the established religion of the country. Several respectable persons were tried and convicted, principally on the evidence of Oates, who was unworthy of credit. A bill was brought into parliament to exclude the duke from the throne, which was passed in the commons, but was thrown out in the house of lords. A plot was now invented on the other side, in which the principal protestants were accused of an endeavour to destroy the king. For this, on the evidence of lord Howard, a man of infamous character, lord Russel, who had been zealous in his opposition to the popish succession, Algernon Sidney, and other distinguished characters, were tried and executed. The terror which the measure carried with it intimidated the best friends to their country; it silenced the opposition of the city of London and other corporations, and the duke of York triumphed in the victory which had been obtained by perjury. From this period the reign of Charles was as absolute as that of any monarch in Christendom, but the spirit of freedom, which the people had imbibed, struggled hard against the spirit of obedience, which the clergy attempted to inculcate. Another civil war threatened the nation still more dreadful than the former, as the forces were more equally divided; but fortunately for the peace of the country, the king was suddenly seized with an apoplectic fit, and died in the fifty-fourth year of his age.

Though England, during the reign of the second Charles, was agitated by contending interests, yet commerce continued to increase; its good effects had been duly appreciated, and multitudes were ready to turn their wealth and industry into this course. Many new manufactures were introduced, and many old ones brought to perfection. When France, by shameful and wicked policy, banished her best subjects, the protestants, England opened her arms to receive them, and with them she received large accessions of national wealth. To the afflictions and exile of this monarch we are indebted for many of our best vegetables which were introduced by his followers from the continent. Science and literature made rapid progress during this reign: Newton and Tillotson; Burnet and Shaftsbury; Butler and Dryden flourished at this period: the Royal Society was instituted, and from this time our countrymen took the lead in every useful science, and they have maintained their superiority to the present hour. Nor must it be forgotten, that if Charles was the first of our monarchs who claimed the protection of standing forces, yet to him and his brother we are indebted for some very important improvements in the art of ship-building, an art which has given us a preponderating balance among the nations of the world, and which, we trust, will, in the hands of an over-ruling providence, preserve us from that overwhelming ruin in which almost all the empires of the continent are involved.

The opposition, which during the late reign had shaken the throne, vanished almost entirely at the accession of James II. The affection of the people seemed to know no bounds when the king, as it were, spontaneously made a declaration in favour of the church of England. That church, to flatter the prejudices of the present and late monarchs, had authoritatively from the pulpit and press pronounced all resistance to a

reigning sovereign unlawful: a doctrine which, however pleasing it might be to the feelings of the king, proved fatal to his peace, and, in the event, drove him from the kingdom. The army and people supported him in crushing an ill-concerted rebellion of the duke of Monmouth, who pretended to be the lawful son and heir of Charles II., and had assumed the title of king. The duke was taken and was beheaded; and some hundreds of his adherents lost their lives likewise by the instrumentality of judge Jeffries and colonel Kirke, names that have been deservedly handed down to posterity with every infamy that can attach to human nature. James, with such assistance, determined to try how far the church of England would agree in the practical assertion of the doctrine of non-resistance. He was set upon introducing popery as the established religion of the country. He laid pretensions to a power of dispensing with the known laws; he instituted an illegal ecclesiastical court, and openly received and admitted into his privy council the pope's emissaries, and gave them more respect than was due to the ministers of a sovereign prince. He sent an embassy to Rome, and received, at his court, the pope's nuncio, and, to crown all, his encroachments upon the civil and religious liberties of his people were carried beyond all bounds, even to the disgust of Roman catholics themselves; and the pope was too good a politician not to know that the course taken by James must eventually ruin the cause which he professed to advocate. The church of England took the alarm, when the king had ordered a declaration to be read, by which every restraint on popery was removed. Seven bishops refused to comply with their sovereign's order, and presented a petition to excuse their refusal. They were cited before the council to answer for their conduct, and adhering to their resolution, were committed to the Tower, prosecuted by the attorney-general for sedition, tried, and gloriously acquitted. The joy of the people, on this occasion, was inexpressible: the city and the country seemed at once to catch the shouts of exultation. James heard the intelligence with fullen silence, and evident indignation, while he was at dinner in his camp. From the church he turned to his army, who proved equally hostile to his views. Opposition, however, served only to increase his zeal, till at length some of the principal people in the country resolved to apply for relief to William, prince of Orange, who was at once the nephew and son-in-law of James II. William, who was an able politician, and ambitious of wearing the crown of England, readily listened to the proposals made him, embarked in their cause, and landed a large army almost before his designs were suspected by the court of James, who, in a few days deserted their old master, and sought protection from the new. The old king was now deeply convinced of his errors, and would gladly have retracted his measures, but it was too late: he found himself abandoned by his army and fleet, and learnt, with apparent consternation and horror, that the prince of Denmark and his favourite daughter Anne had gone over to the prince of Orange. On this intelligence he is said to have wept bitterly, exclaiming, "God help me, my own children have forsaken me." He now hung over the precipice of destruction, invaded by one son-in-law, abandoned by another, hated by his subjects, and held in utter detestation by the friends and relations of those who had suffered by his cruelty. He assembled the few noblemen who still adhered to his cause, and demanded their advice and assistance. Addressing himself to the earl of Bedford, father to lord Russel, who had been beheaded at the instigation of James in the preceding reign, "My lord," said the dejected monarch, "you are an honest man, have great credit, and can do

me signal service." "Alas! sir," replied the earl, "I am old, and very feeble, and can afford you but little service, but *I once had* a son that could have assisted you in this extremity, but he is no more." James was so struck with the reply, that he could not speak for many minutes. After this he almost instantly resolved to abandon his country, and seek for himself, his queen, and his son, real or pretended, then only six months old, an asylum in France, where he passed the remainder of his life among a people who pitied, ridiculed, and despised him.

From this moment the constitution of England, which had fluctuated for ages, was fixed. The nation, represented by its parliament, determined the long contested limits between the king and the people: they prescribed to the prince of Orange the terms by which he was to rule, and appointed him king jointly with Mary, who was the next protestant heir to the crown. They were shortly after crowned by the titles of William III. and Mary, king and queen of England. The prince had his ambition amply gratified, and his wisdom was repaid with that crown which the folly of his predecessor had thrown away.

The power of William was limited on every side, and he met with an opposition from parliament which he did not expect. His chief object was to humble the power of France, and he fully anticipated the utmost efforts of the English to second his views, but he found them more intent upon guarding their domestic liberties than eager against continental powers; notwithstanding this, his reign was spent in an almost uninterrupted course of hostilities with France, at an expence she had never known before. The nation had grown cautious through the experience of the two last reigns, and he gave his consent to the "bill of rights," by which the liberties of the people were confirmed and secured, though not in so ample a manner as might have been done at a crisis when a crown was bestowed by the free voice of the people. The last two kings had made a very bad use of the whole national revenue, of which they had an unlimited use, and it was found in their hands quite sufficient to raise and maintain a standing army. The revenue was now divided, part of it was allotted for the national service of the year, and was to be accounted for to parliament; and part, which has ever since been denominated the civil list money, was given to the king for the support of his house and dignity.

William was averse from persecution, and began his reign by attempting a repeal of those laws that enjoined uniformity of worship, and though he could not do all he wished, yet he obtained practical toleration for the dissenters; and the laws against the papists were rarely executed. He was, however, a stickler for what he regarded as the privileges of the crown, and often controverted, and remonstrated against the views of his parliament, and was, not unfrequently, arbitrary in his councils. He opposed with the utmost vehemence the bill for triennial parliaments, and, when it had actually passed the two houses, he refused to give it his royal assent. The house of commons, who are or ought to be the representatives of every individual in the country, took fire at this abuse of the royal prerogative, and voted, with becoming spirit, "that whoever advised the king to this measure was an enemy to his country," and no king has since ventured upon so outrageous a proceeding. The bill, thus rejected, lay dormant till the next sessions, when William found himself obliged to comply. The same opposition and the same success attended a bill for regulating trials in cases of high treason, by which the accused was allowed a copy of his indictment, and a list of the names of his jury, two days before his trial, together with counsel to plead in his defence, and that no person should be indicted

but upon the oaths of two witnesses. It was by incessant struggles against the crown that the invaluable rights of the people have been transmitted to their posterity; and a just regard to these rights, civil and religious, was what led them to agree to the revolution. In other respects they had no reason to desire a change, nor can it with justice be imputed to the English that they affect important national revolutions. When James was dismissed, the wealth and prosperity of the nation were at their highest pitch, the tonnage of their shipping, both for merchandize and war, had been nearly doubled in the last 25 years: the increase of the customs, the surest test of increasing commerce, and the annual rental were nearly in the same proportion. Hence a strong party was formed against the king's ambitious and warlike pursuits, which were not always successful, and which drained the country of much wealth. The Irish were still desirous of a Stuart king, as were many of the English, though they spurned the idea of having even James forced upon them by the right of conquest. Parliament enabled the king to reduce Ireland, and to gain the famous battle of Boyne, (see *BOYNE*,) which crushed all the hopes of the exile king, and in 1692 the marine of France, which had hitherto vied with that of England, received an irrecoverable blow in the defeat at La Hogue.

Invasions were threatened, and conspiracies discovered every day against the government, and the supplies required to carry on a continental war obliged the parliament to open new resources for money. A land-tax was imposed, and every one's lands were taxed according to their valuations given in by the several counties. To this reign also we are indebted for the most important operation in finances that ever took place, which was the carrying on the war by borrowing money upon parliamentary securities, and which form what are called the public funds. The projector of this scheme, which has been acted upon, beyond the limits of human imagination, (see *DEBT, National*,) was Mr. Charles Montague, afterwards lord Halifax. The argument on which he depended to carry his plan into effect, was that it would oblige the moneyed part of the nation to become the zealous and steady friends of the revolution, because, after having lent their money to the nation, they could have no hopes of repayment or even of interest for it, but by supporting the existing government.

Notwithstanding the advantages which the nation derived from the administration of William, he was subject to so many mortifications from his parliament, that he seriously resolved to abdicate his throne, a resolution which he with difficulty abandoned, and certainly with the hope of being supported more effectually in the war with France, but he was in a great measure disappointed, and obliged to conclude the peace of Ryswick in the year 1697; and in the general pacification, the only equivalent obtained by the nation for an immense waste of blood and treasure, was the king of France's acknowledgment of king William's title to the crown.

One of the last and most important acts of this reign was the passing of a bill for settling the succession to the crown in the house of Hanover, which received the royal assent in June 1701. Shortly after this the king felt his constitution giving way, which he endeavoured to counteract by the exercise of riding, and in one of his excursions to Hampton court, his horse fell under him, and he himself was thrown off with such violence that his collar-bone was severely fractured, an accident which, in a few days, put an end to his life, in the 52d year of his age, and the eleventh of his reign. The character of this prince will be more particularly given under his own name. It may, however, be observed

in this place, that he was ill formed for acquiring popularity: his manners were cold and forbidding, and he sometimes seemed almost lost to those principles of liberty, for the support of which he had been raised to the throne. Nevertheless, the rescue and preservation of religion, and public liberty, were the chief glory of William's reign, for under his auspices England suffered grievously in her actions both by sea and land, and the public debt at the time of his death amounted to the sum of fourteen millions sterling.

The successor to William was Anne, the second daughter of king James by his first wife. She ascended the throne in the thirty-eighth year of her age, having suffered many severe mortifications during the reign of the late king, but upon her accession she followed his steps, and shortly after declared war against France, appointing the earl, afterwards the duke of Marlborough, to the command of her armies. Under this general many important victories were achieved. Those of Bleenheim and Ramillies gave the first effectual checks to the French power. By the former, in 1704, the emperor of Germany was saved from impending destruction, and 20,000 of the enemy were said to have been killed, wounded, or drowned in the Danube. About the same time sir George Rooke reduced the famous fortress of Gibraltar, which still remains in our possession a monument of the bravery and talents of the English admiral. The battle of Ramillies, fought in 1706, was of the utmost importance to the cause for which the war was undertaken; viz. to place Charles duke of Austria on the throne of Spain, for immediately after that victory, the states of Flanders assembled at Ghent, and recognized Charles for their sovereign. In Spain itself the English were unsuccessful; the burdens of the war falling chiefly on this country, the people, who are ever delighted at victory, began to murmur at the taxes imposed on them. Other circumstances led to disputes respecting the prerogative, the succession, and religion, which created great ferments in the nation and parliament. Negotiations for peace were carried on some time, but without success. At this period the leading parties in the nation were whigs and tories, at the head of the former was the duke of Marlborough, who supported by the queen was for a continuance of the war, in which her majesty concurred, till means were found to convince her, that it would finally prove ruinous to her and the people, and that the whigs were inimical to the national religion. The cry of "the church is in danger," at length displaced the whigs, and even drove the duke of Marlborough from the command of the army, an act which excited the astonishment of all Europe, for so numerous had been the victories acquired by his valour, and so high was his reputation, that his name was equivalent to an army. There is little doubt that whatever the faults of the whigs might have been, the honour and interests of the nation were sacrificed to court intrigues and private cabals. In the midst of all the disputes the whigs accomplished the union between the two kingdoms of England and Scotland, which has proved of great benefit to both, but which at the time excited the most violent clamours against the projectors. The English expected nothing from the union of so poor a nation, but a participation of their necessities: they contended it were unjust that while Scotland was granted an eighth part of the legislature, it yet should be taxed only a fortieth part of the supplies. The Scots, on the other hand, conceived that their independency would be wholly destroyed, and the dignity of the crown betrayed; they dreaded an increase of taxes, and were not very anxious for an increase of trade. After some ineffectual struggles the Union was effected: Scotland was no longer to have a parliament, but to send

## ENGLAND.

sixteen peers, chosen by their nobility, and forty-five commoners, to the English parliament, and from that period the two kingdoms were called by the common name of Great Britain, and all the subjects of both were to enjoy a communication of privileges and advantages.

In 1712 conferences for negotiation between England and France were opened, which led to peace. This was condemned by the whigs as injurious to the honour and interest of the nation. The majority of the house of lords inclined to that party, but that of the other house was tories. The queen, dreading that the lords might reject the terms of peace, by an unprecedented exercise of her authority, created twelve peers at one time, which secured the approbation of the parliament for the peace. The remainder of this reign was a scene of contention between the two parties. Each reviled the other in turn, and these commotions served still more to impair the queen's health, till at length she felt herself unequal to the duties of her station. She sunk into a state of insensibility, and found a refuge from her anxiety and cares in lethargic slumber. Every precaution was taken to secure the succession in the house of Hanover, and orders were sent to the heralds at arms to be in readiness to proclaim the elector of Brunswick king of Great Britain. The day before the queen died she seemed to revive, rose from her bed, and walked about, when, casting her eyes on the clock that stood in her chamber, she continued to gaze for some time, and being asked what she saw more than usual, she replied only with an expressive but dying look, and about seven o'clock the next morning, Aug. 1, 1714, she expired in the thirteenth year of her reign. The national debt had, during this reign, increased from fourteen to fifty millions. See ANNE, CHURCHILL, &c.

With this princess terminated the line of Stuarts, which, from the accession of James I. 1603, had swayed the sceptre of England one hundred and eleven years, and that of Scotland 343 years. On the death of queen Anne, there was still left the son or supposed son of James II. who had been acknowledged king by the court of France on the decease of his father in 1701. In behalf of this prince, rebellions were excited in England in 1715 and 1745. He resided at Rome, and kept up an appearance of a court till his death in 1765, leaving two sons, who are since dead and without issue.

By the act of succession George I. son of Ernest Augustus, first elector of Brunswick, and Sophia grand-daughter of James I. ascended the British throne; his mother, who would have been next in succession, having died a short time before. He arrived in England with strong prepossessions against the tory ministry, most of whom he displaced, without producing much effect in England, but in Scotland a rebellion was excited by some of the leading men of that country, who paid for their temerity the forfeit of their lives. Commotions and riots were raised in London, Oxford, and other parts, but these were happily suppressed, and the ringleaders in various instances were made examples of justice. The earl of Oxford, who had negotiated the peace of Utrecht, was charged with high treason on that account, but the prosecution was abandoned. The situation of affairs would not permit the ministry to venture upon a new parliament, and the members of that which now existed voted a continuance of their duration from three to seven years, one of the greatest and most indefensible stretches of parliamentary power ever known. Several other measures, hostile to liberty and the principles of the existing constitution, took place at the same time. Mr. Shippen, a member of parliament, was committed to the Tower for asserting in his place, that the king's speech was better cal-

culated for the meridian of Hanover than of London; and a young man, a printer, was actually hanged for a pamphlet, said to have been scarcely deserving of animadversion. George I. however sagacious, and in many respects moderate, was too much attached to his German dominions, and rendered England in a great measure subservient to them. He quarrelled with the czar of Muscovy about their German concerns, and had nearly involved this country in a war with Charles XII. of Sweden, for having as elector of Hanover purchased Bremen and Verden of the Danes. In 1718, he quarrelled with Spain on account of the quadruple alliance that had been formed between Great Britain, France, Germany, and the States General, and admiral sir George Byng, by his orders, destroyed the Spanish fleet. The war was quickly terminated by the Spaniards delivering up Sardinia and Sicily, the former to the duke of Savoy, and the latter to the emperor, and by the king of Spain consenting to sign the quadruple alliance, in which England was very little if at all interested. See ALLIANCE.

The next thing of importance was the securing the dependency of the Irish parliament upon that of Great Britain. The house of peers in England had reversed a decree made by the Irish house, which excited long, animated, and even bitter discussions, till at length a bill was brought into the English parliament, by which the Irish house of lords was deprived of all right of final jurisdiction, which, notwithstanding the most violent opposition from several leading members of both houses, was carried by a great majority. The ferment occasioned by these discussions was followed by the South Sea scheme, which promised immense wealth to those who engaged in it, but which left a large part of the nation in distress and ruin. (See BUBBLE.) Justice was demanded, by petitions from all parts, upon the contrivers of the scheme, and the nation seemed, as to a man, highly exasperated. During these transactions, the king, with serenity and wisdom, presided at the helm, influenced his parliament to pursue equitable measures, and, by his councils, endeavoured to restore the credit of the nation. The discontented availed themselves of public calamities, and made another attempt against the reigning sovereign. Their designs were soon detected, and Christopher Layer, a young gentleman of the Middle Temple, was convicted of treasonable acts, and suffered death on the account. Several noblemen and other persons of distinction were suspected of being in the plot, but of these the bishop of Rochester was the only victim who was banished the kingdom for life. After the ferment which this plot occasioned was over, the transactions of the reign were few and less important in their consequences. The ministry, who were all in the interest of Hanover, ventured upon several bold measures, in some of which the national interest, if not honour, was evidently sacrificed to that of the electorate. The crown of Great Britain was engaged in every continental dispute, however remote it was from her own interest. Treaties lately concluded with Spain were again broken, and admiral Hosier was sent to intercept the Spanish galleons from America, an expedition which proved as fatal as it was inglorious. The admiral and most of his men perished by epidemical diseases, and the hulks of his ships rotted so as to render them utterly unfit for service. To retaliate, the Spaniards undertook the siege of Gibraltar, and with similar success. New treaties were set on foot, France offered its mediation, and a reconciliation was effected. The king died, as he was travelling to his Hanoverian dominions, at Osnaburgh, on the 11th June 1727, in the thirteenth year of his reign. During his reign the sinking fund for diminishing the national debt was instituted. See DEBT National, FUNDS, &c.

Upon

Upon the death of George I. his son George II. ascended the throne, with a predilection for his Hanoverian dominions similar to that of the late king. He chose for his first minister sir Robert Walpole, who had filled the same high office under his father. This able minister was a decided enemy to war, which, in some instances, led him into difficulties both at home and abroad. His administration will be more properly considered under the article attached to his name, (see WALPOLE,) but justice requires of us to observe, that notwithstanding some of his measures, as an attempt at the introduction of the excise laws, were liable to great censure, yet he was friendly to the existing laws: he filled the courts with able and upright judges, and he has not been charged with any attempt at the violation of the known law of the kingdom, and under his administration the press was under little or no restraint. His pacific system more than repaid to the nation all that was required to support it, by the increase of her trade and the improvement of her manufactures. The great objects of controversy during the early part of this reign were the national debt, and a standing army. Demands for new supplies were made every session of parliament, either for the purpose of securing friends on the continent, or of guarding the internal polity, or for enabling the ministry to act vigorously in conjunction with their allies abroad. These were as regularly opposed as they were made: the speakers of the country party ever insisted, that the English had no business to embroil themselves with the affairs of the continent; that expences were incurred without prudence or necessity; and that the increase of the national debt by multiplying taxes, would in the end become intolerable to the people. A motion was made to revert to the old system of triennial parliaments, as they had been settled at the revolution. The advocates for this measure asserted that the septennial act was an encroachment on the rights of the people; that it was introductory to the monstrous corruptions of government: that during the continuance of that parliament which prolonged its existence from three to seven years several severe laws had been enacted; that by one of these a man might be removed, and tried at any place where the jury might be found favourable to the crown, and where a prisoner's witnesses could not and dared not come; that by another, a justice of peace was empowered to put the best subjects to death after reading the riot act. The ministry was, however, triumphant, and the opposition, who, unquestionably, had the weight of argument on their sides, complained that debate was useless, and that it was wholly impossible that reasoning could prevail over the corruptions that were secretly practised by the minister. Despairing, therefore, of being able to stem the torrent of corruption, they retired to their seats in the country, and left the ministry an undisputed majority in the house.

In November 1737, queen Caroline, consort to the king died; at this time the king and his son Frederick the prince of Wales were at variance. The latter complained that through Walpole's influence he was deprived not only of the power but the provision to which his birth was entitled. The king forbade him his presence, and gave orders that none of his friends should be admitted at court. A motion was made in the house of commons for increasing the prince's settlement, which was fifty thousand pounds; this was opposed by sir Robert Walpole, and rejected by a large majority. The prince now placed himself at the head of the opposition with so much firmness, that it was seen Walpole's power was drawing to a crisis; but it was not till the year 1742 that he resigned his employments and was created earl of Orford. The king bore the loss of his minister with the

greatest equanimity, and even conferred titles of honour, and posts of distinction upon the heads of opposition. Circumstances also arose which induced him to take a leading part in a continental war: in opposition to which a rebellion in behalf of the pretender was excited in 1745 in Scotland. Charles, the son of the pretender, landed in the Scottish islands, and soon found himself at the head of 1500 men. Manifestoes were widely dispersed, inviting the highlanders to join in the cause: few, however, seemed willing to hazard the dangers of the enterprize. Its boldness astonished Europe; it awakened the fears of the pusillanimous, the pity of the wise, and the loyalty of all. The whole kingdom seemed unanimously bent upon opposing the enterprize which they were sensible, as being supported only by papists, would be instrumental in restoring popery. The rebels advanced to Perth, where, instead of proceeding with increased rapidity, they staid to proclaim the prince's father king. The prince was again successful at Preston Pans, and marched to Edinburgh; here he wasted his time in dissipation and parade, till an opportunity was given to the king to send against him an effectual force under the duke of Cumberland. The battle of Culloden on the 15th of April 1746, put an end to all hopes of the pretender: the victory on behalf of the king was complete, but the merciless fury of the conquerors upon the fallen disgraced the cause, to which every friend of his country wished success. The duke ordered nearly forty deserters to instant execution, and the royal army spread terror wherever it came, and after a few days the whole country was one scene of slaughter, desolation, and plunder; justice was forgotten, and every virtue seemed to be lost in the most savage vengeance. The government on this occasion was not a little indebted for the support it received to the national debt. The Jacobite party had hoped to ruin public credit, but common danger abolished all distinctions, and united them in defence of private property. The merchants agreed to receive bank notes in payment, which prevented the mischief that was hoped for by a run upon the bank. The defeat of this rebellion in the year 1746 did not restore tranquillity to Europe; it was not till after various successes in different parts of the globe that the preliminaries of peace were signed in April 1748, and in the October following a definitive treaty was concluded at Aix-la-Chapelle. In the prosecution of this war the balance of gain, as far as wealth was concerned, was evidently in favour of Great Britain, and many private persons made it subservient to the attainment of vast fortunes. In the following year, the interest of the national debt was reduced from four to three and a half *per cent.* at which rate it was to continue for the next seven years, when it was to suffer a farther reduction to three *per cent.* This, says the historian, was the boldest stroke of financing that ever was attempted perhaps in any country, consistently with public faith, for the creditors of government, after a trifling ineffectual opposition, continued their money in the funds, and a few who at first sold out were glad, in a short time, to have it placed under the same security.

At this period Mr. Pelham was the minister of the country, who turned his attention to the improvement of commerce, manufactures, and fisheries, the benefits of which descended to posterity. A new treaty of commerce was signed at Madrid, between Great Britain and Spain, by which, in consideration of 100,000*l.* the South Sea Company gave up all their future claims to the Assiento contract, by virtue of which that company had supplied the Spanish West Indies with slaves from the coast of Africa. (See ASSIENTO.) In March 1750, his royal highness Frederic prince of Wales died, to the regret of the nation: and in the following year an

act was passed for regulating the commencement of the year, by which the old style was abolished, and the new style established, which was done by linking eleven days in 1752, and from that time the year was to begin the first of January instead of March. (See CALENDAR.) In 1753 the famous act was passed for preventing clandestine marriages, which at the time excited the most violent opposition, as replete with the most injurious consequences to the liberties and morality of the people, and as making an impassable line between the rich and the poor: and about the same time an act equally, or even more unpopular, as attacking the religious prejudices of the people, was passed. This was a law for naturalizing the Jews, which, though carried through great opposition, was in the next session repealed. The game laws were also introduced about this period; by these none but men possessed of certain property could have the privilege of carrying a gun, or of otherwise destroying game, though on grounds which they rented themselves. This measure was supposed to be a violent encroachment on the liberty of the subject; that it would necessarily damp the martial spirit of the lower orders of society, by preventing them from handling those arms which might one day be necessary to defend their country; and at the same time, that it gave the rich the sole enjoyment of a pleasure, which before had been considered as the common privilege of humanity. "Such," says a contemporary writer, "were the laws passed at this period, through all which a spirit of aristocracy was discerned by some. The body of the rich, no longer fearing oppression from the throne, or an infringement of their own liberties, now began to lean heavy on the poor, and to consider the interests of that useful part of the society as entirely distinct from their own. They never omitted, however, their usual addresses to the throne; and this session (1756) was remarkable for an address of thanks to his majesty, for maintaining, and rendering permanent, the general tranquillity of Europe, at a time when war was kindling in almost every quarter of the world."

To the conduct of this war Mr. Pitt was called, as secretary of state, and head of the administration. He had long signalized himself as a bold, eloquent, and energetic speaker, and he soon proved himself a most able and spirited minister. In this war the English in Europe, in Asia, and America, achieved wonders: they were every where victorious: almost all the possessions of the French in North America and in India fell into our hands; and at the battle of Minden, in Germany, seven thousand of our countrymen defeated an army more than ten times as large. The English for some time bore the increasing burdens of warfare with cheerfulness; and rendered, by every means in their power, the just tribute of praise to the talents and activity of the minister. But at length, glutted almost with victory succeeding upon victory, they began to reflect upon the probable advantages that might result from a continuance in war, when it was evident that the conquests made in Germany must ever be foreign to the real interests of Great Britain; that they were waging an unequal war, and adding new loads of taxes to those already difficult to be borne, for conquests which they could neither preserve nor enjoy. Such were the growing discontents of the people, when the French shewing some disposition to treat for peace, and the charges of the war beginning to amount to eighteen millions a-year, inclined the British ministry to listen to the proposals offered them. A negotiation was accordingly entered upon, but without success. This was in the autumn of the year 1760, and on the 25th day of October, 1760, George II., without any apparent symptoms of disorder, was found expiring in his chamber. He had arisen at his usual hour, intending to

walk out, but being left alone, he was heard to fall down upon the floor; the noise of the fall brought his attendants into the room; he desired, in a faint and faltering voice, that the princess Amelia might be sent for, but before her arrival he expired, in the 77th year of his age, and the 33d of his reign, in the midst of victory, and at that very period, when the universal enthusiasm of conquest began to subside into more sober reflections. The character of this prince will be given under his own name. He was succeeded by his grandson George III., the present sovereign, who ascended the throne with great advantages. He took the opportunity which his first speech to parliament gave him, of appealing to the prejudices and affections of his people. "Born and educated in this country," said he, "I glory in the name of Briton, and the peculiar happiness of my life will ever consist in promoting the happiness of a people whose loyalty and warm affection to me I consider as the greatest, and most permanent security of my throne. The civil and religious rights of my loving subjects are equally dear to me with the most valuable prerogatives of my crown." The first acts of this reign were calculated to convince the people that the war in which they were engaged should be carried on with energy; very brilliant successes, and important conquests, were the result of the plans adopted by Mr. Pitt, who felt himself responsible for almost all public measures. When, however, he found his influence in the cabinet declining, through the supposed intrigues of the earl of Bute, he resigned his high situation, declaring he would no longer lie under the responsibility of measures which he was not allowed to guide. Mr. Pitt retired in October 1761, upon a pension of 3000*l.* per ann. and, at the same time, a peerage was conferred upon his lady. These grants were, by his enemies, held out as proper subjects to excite the popular clamours against the patriotic minister. At first they succeeded, but in a short time an almost general discontent prevailed in the nation, on account of his removal from office, in the midst of a war, which he had conducted with so much honour to himself and to his country, and in a manner that had excited the astonishment of Europe. The war was still pursued with vigour, and the plans of Mr. Pitt, of which the new minister availed himself, led to important victories both by sea and land.

Early in the year 1763, peace was agreed upon, and of so little importance had the war been to the interests of the English, who had been almost uniformly victorious, and who had acquired by their valour many foreign possessions, that it was agreed a mutual restitution and oblivion should take place, and each party sit down at the end of the war in the same situation in which they began it. The peace excited much opposition, because the terms were thought extremely inadequate to what might have been expected from the numerous and brilliant victories and advantages obtained in the course of a long war. From this period various causes contributed to occasion a spirit of discontent in the nation. On the 30th of April, 1763, three of the king's messengers entered the house of Mr. Wilkes, member of parliament for Aylesbury, and seized his person by virtue of a warrant from the secretary of state, which directed them to seize the authors, printers, and publishers, of a seditious and treasonable paper, entitled the North Britain, N<sup>o</sup> 45. This work contained strictures on his majesty's speech, and Mr. Wilkes was suspected to be the author. He was accordingly arrested, examined, and closely imprisoned, which gave rise to discussions on the legality of general warrants, which were in the end declared illegal, and a gross violation of the liberty of the subject. (See WARRANTS, General.) Mr. Wilkes was for this and other publications expelled the house,

## ENGLAND.

house, and in 1764 a sentence of outlawry was issued against him.

In 1765, under the administration of Mr. George Grenville, an act was passed for laying a stamp-duty on the British colonies of North America. This kindled a flame in that quarter of the globe, which finally led to a separation of the colonies from the mother country, and established the independence of America. (See AMERICA and UNITED STATES.) In the year 1768 Mr. Wilkes returned to England, was prosecuted, convicted, and fined in the sum of 1000*l*. He carried with him the voice of the people, whose cause he was supposed to vindicate, and was again elected member for Middlesex; and was again expelled. After the expiration of the term of his imprisonment, in the year 1771, he was elected sheriff of London, and afterwards chosen member for the county of Middlesex, when he was permitted quietly to take his seat; and in the year 1775 he was elected lord mayor of London, an office which he executed to the satisfaction of his fellow-citizens. In 1783 all the declarations, orders, and resolutions of the house of commons, respecting his election for the county of Middlesex, were ordered to be expunged from the journals of that house.

In the year 1772 the clergy petitioned the parliament for relief in matters of subscription to the 39 articles, praying to be restored to their undoubted right of interpreting scripture for themselves, without being bound by any human explanation of it, or being required to acknowledge by subscription or declaration, the truth of any formulary of religious faith and doctrine whatever, excepting the Holy Scripture itself. The petition was presented by sir William Meredith, who, with other members favourable to the principle, enforced it by many arguments drawn from the principles of toleration. It was, however, rejected by a large majority. A bill was shortly after brought into the house to prevent the descendants of his late majesty from marrying without the consent of his majesty, his heirs, and successors, which was carried very rapidly through both houses, and passed into a law. A petition was now presented by the dissenters, praying to be relieved from the hardship of subscribing to the articles of a church to which they did not belong. This petition was received, and a bill brought into the house founded upon it, which was carried by a large majority in the commons, but which was rejected in the house of lords. From this period the whole interest of the country was turned to the contests with America, to which we have already referred. The enormous expences occasioned by this war excited much and almost general discontent among the people, who began to call aloud for an economical reform in the various departments of the state. Meetings were held in various counties of the kingdom, at which great numbers of freeholders were present, who agreed to petition the house of commons, "that before any new burdens were laid upon the country, effectual measures might be taken by that house to inquire into, and correct the abuses in the expenditure of the public money; to reduce all exorbitant emoluments; to rescind and abolish all sinecure places, and unmerited pensions; and to appropriate the produce to the necessities of the state." In the beginning of the year 1780 these petitions were taken into consideration, and some trifling reforms took place. In some instances, the minister, lord North, was left in a minority, and in many others he was obliged to use every exertion to carry his measures. In a very full house, and by a small majority, certain officers under the crown were excluded from having seats in the house of commons: this they hoped to follow by other arrangements favourable to the rights of the people; but, in a short interval, the

minister was enabled to apply arguments not generally understood, but strongly suspected, which gave him a preponderance in the house, and which enabled him to stop the progress of reform. The people were dissatisfied, and a spirit of discontent prevailed in almost every part of the kingdom. About this period, the hardships which individuals, professing the Roman Catholic religion, had laboured under, awakened the consideration of the liberal part of the people: and some persons of high consideration in the state undertook their cause, and fully expected they should obtain for them that relief which the nature of their case required. The Catholics presented a dutiful and loyal address to the king, containing the strongest assurances of affection and fidelity to his person and the civil government of the country. This address, which was drawn up with great care, and which contained sentiments of the most unexceptionable nature, was signed by several Roman Catholic peers, and 63 commoners of rank, fortune, and influence in the country. The advocates of the cause were aware that the prejudices of the lower classes were hostile to an extension of the privileges of the Catholics, whom they had been accustomed to regard as persecutors from principle, and as desirous of subverting the Protestant faith. But sir George Saville made a motion for the repeal of certain penalties which were attached to the profession of the Catholic religion. He was seconded in his exertions by Mr. Dunning, who laid before the house an account of the statutes still existing against the Catholics, by which, among other grievances, it was made high treason in any native of these realms to teach the doctrines or perform divine service according to the rites of that church; the estates of persons educated abroad in that persuasion were forfeited to the next Protestant heir; a son, or any other, the nearest relation being a Protestant, was empowered to take possession of his own father's or nearest kin's estate, during their lives; a Roman Catholic was disabled from acquiring any legal property by purchase. In consequence of these and such like representations, the motion made in favour of the Roman Catholics was received without a dissenting voice, and a bill in pursuance of its intent was brought in and passed both houses. This act seemed to give little offence to persons of any class in England, but in Scotland it excited much indignation, riots ensued, and some houses and chapels were destroyed. The contagion at length reached England: a number of persons assembled themselves together with a view of promoting a petition to parliament for a repeal of the late act in favour of the Papists, and they assumed the title of "The Protestant Association." Of this association lord George Gordon was the president: who, at the head of 50,000 men, presented a petition to the house of commons on the 2d day of June 1780. At first the petitioners behaved with order and decency, but they soon became violent against the members of the two houses who had been friendly to the cause of toleration, some of whom narrowly escaped with their lives. From this time till the 7th of June, London was the scene of the most atrocious crimes: houses, chapels, and prisons, were broken open, plundered, and burnt. In one night, and at the same hour, it is said, there were 36 buildings on fire. Attempts were made on the bank, but such precautions had been taken as to render that place invulnerable. At length by the exertions of the military, who killed and wounded great numbers of the rioters, the tumult was suppressed, and the metropolis restored to order and tranquillity. Numbers were afterwards tried for aiding and abetting in these scenes; some were convicted and executed, and others acquitted; and the president lord George Gordon

Gordon was committed to the Tower on a charge of high treason, for which he was afterwards tried and found "Not Guilty."

War continued to rage, and from America it had spread to almost every part of the world, and the English found themselves engaged in a contest with France, Spain, and Holland: but in the beginning of the year 1762 the opposition succeeded in forcing ministers to a pacification. Peace was accordingly concluded, but not such a peace as met the general wishes of the people, and those who had made it were obliged to resign their places to the famous coalition ministry under lord North and Mr. Fox. By the latter a bill was brought into parliament, for newly regulating the government of the East India Company, which occasioned a great ferment in the country, and which finally drove the author of it, and his party from the helm, who were succeeded by the late Mr. Pitt and his friends. One of the first acts of this minister was a new East India bill, which was passed by a great majority: and shortly after, he became the advocate of parliamentary reform, a cause which he had espoused before he came into place, and which he pledged himself to use his utmost endeavours to carry into effect. His plan was rejected, and from that time he never seriously attempted to realize the expectations which he had excited among the friends of liberty. The next important measure which he introduced to the notice of parliament was the proposal of a sinking fund to be applied towards discharging the national debt. (See DEBT, national. Sinking Fund, &c.) We shall also refer our readers to his public administration: to the article REVOLUTION, French, for the various occurrences that took place in this country from the year 1788; to the article SLAVE Trade for an account of the proceedings on that subject to its final abolition: to the article TEST act for the attempts made in this reign to obtain a repeal of those obnoxious laws, &c. &c. Henry's Hist. Rapin. A.G. Regia. Hume. Belsham. Biog. Brit. &c.

ENGLAND, *Little, beyond Wales*, in *Geography*, is a portion of country lying along the south-western coast of South Wales, inhabited by the descendants of a colony of Flemings; who came over from Flanders, and settled here in the reign of king Henry I. Camden says, the occasion of their emigration was an inundation of the sea, by which a great part of the Low Countries was overflowed. But it has been stated, with more probability, that it was the policy of that wise monarch to place a people opposite in their language, manners, and opinions to the Welsh, to assist in his favourite project—the subjugation of the country. Another colony from the same country was incorporated with the first, in the time of Henry II., to which occasionally were added numerous Anglo-Normans, and others from the English army. At first these people were confined to the comot of Rhos, which district still more particularly retains the name of Little England beyond Wales. But their numbers increasing in the course of time, they soon spread along the whole coast, from the lordship of Comes to the mouth of the river Tave. And this part of the principality is still divided into two districts, denominated Englishery, and Welshery. The latter, occupied by the original inhabitants, contains the cantreves of Comes, Cilgerran, part of Arberth, and Dewisland. The former comprises the remainder of Arberth, and the cantreves of Rhos, Castell-Martins, and Dogleddy; and is inhabited by the descendants of the Flemings. Like their ancestors, they are a hardy, industrious, and adventurous race. The dispositions of the two people are equally striking

and adverse. While the Welsh are hot, easily irritated, and obstinately tenacious; these are not easily provoked, are averse to contention, and avoid litigation. Both are distinguishable by their mode of dress, manner of living, the style of their buildings, particularly in their churches; and the names they respectively give to places. All these strongly point out the line of demarcation between them. In the Welshery, not a word of English is heard spoken, while in the next village within the Englishery, not a word of Welsh. The language of the latter district is not much different from the common dialect of England, except in some parts of Rhos and Castle-Martin. The two people avoid all commerce as much as possible, mutually considering each other in a degrading light; and even a pathway will divide them in the same parish. To such an extent is this personal detestation carried among the lower classes, that a matrimonial connection between the opposite parties is considered by both an unfortunate event. The Flemings, however, eventually proved a blessing to Wales, as well as England; by their introduction of the woollen manufactures. And a work, which proves their industry and improving spirit, is yet visible. It is a road of great extent made by them, and still called Fleming's way. Evans's Tour in South Wales.

ENGLAND, *New*, comprehending the *Northern* or *Eastern States* of North America, lies around the great bay which sets up N.W. between cape Cod and cape Sable, between 41° and 48° N. lat., and between 1° 30' and 10° 15' E. long. from Philadelphia, and is bounded N. by Lower Canada; E. by the province of New Brunswick and the Atlantic ocean; S. by the same ocean and Long-island Sound; and W. by the state of New York. It lies in the form of a quarter of a circle; its W. line beginning at the mouth of Byram river, which discharges itself into Long-island Sound at the S.W. corner of Connecticut, lat. 41°, runs a little E. of N. until it strikes the 45th degree of latitude, and then curves to the eastward, almost to the gulf of St. Lawrence. Its extreme length is about 626 miles; its breadth is very unequal, from 100 to 200 miles; containing about 72,000 square miles. This grand division of the UNITED STATES comprehends the states of Vermont, New Hampshire, Massachusetts (including the district of Maine), Rhode Island, and Providence Plantations, and Connecticut; which see respectively. The climate of New England is salubrious, as we may infer from the longevity of its inhabitants; one in seven living to the age of 70 years, and about one in thirteen or fourteen to 80 years and upwards. The most prevalent winds are the N.W., W., and S.W.; but the E. and N.E. winds, which are insalubrious, occur frequently at certain seasons of the year, particularly in April and May, on the sea-coasts. The weather is less variable than in the middle, and especially the southern states, and more so than in Canada. The extremes of heat and cold are, according to Fahrenheit's thermometer, from 20° below to 100° above 0; the medium being from 48° to 50°. The quantity of water which annually falls in New England is from 42 to 48, and yet they suffer here more from drought than in England, where the annual quantity of water is estimated at about 24 inches. Hence it is inferred that the atmosphere is remarkably dry, and thus some have accounted for its singular salubrity. Winter commonly commences, in its severity, about the middle of December; sometimes earlier, and sometimes not till Christmas. The diseases most prevalent in New England are alvine fluxes, St. Anthony's fire, asthma, atrophy, catarrh, colic, inflammatory, slow, nervous, and mixed fevers, pulmonary consumption, quinsy, and rheumatism. The gene-

## ENGLAND.

ral condition of the New Englanders, which precludes the luxury of the rich and the extreme distress of the poor, affords them an exemption from a variety of diseases, to which a greater degree of inequality might expose them. This country presents to the traveller a great variety of surface, consisting of extensive plains, intermixed with vallies of different breadths from 2 to 20 miles, and with mountains of different elevations. Although it may be deemed, upon the whole, to be high and hilly, its mountains are comparatively small, and run nearly N. and S., in ridges parallel to one another. The westernmost range begins in the county of Fairfield, and, passing through the counties of Litchfield and Berkshire, unites with the Green mountains at Williamstown, in the N.W. corner of the Massachusetts, being separated only by the narrow valley of Hoosack river. The highest part of this range is Toghkonuck mountain in Egremont, the south-western corner of the same state. Over this mountain, elevated probably more than 3000 feet above the ocean, runs the boundary between Massachusetts, Connecticut, and New York. The second range is that of the *GREEN mountains*; which see. The third range has the same commencement with the second at New Haven, in a delightful eminence called the East rock, and passing through the counties of New Haven, Hartford, and Hampshire, extends into Canada. The Blue hills in Southington, mount Tom, which is the principal eminence, mount Holyoke, and mount Toby in Sunderland, are the principal summits of this range S. of New Hampshire. This range, which is precipitous and romantic, crosses Connecticut river just below Northampton and Hadley in Massachusetts. The south or eastern range begins at Lyme in Connecticut, and forms the eastern boundary of the Connecticut valley, until it unites with the last-mentioned range in the county of Hampshire; but is less distinctly marked by eminences than the others. The chief single mountains are Saddle-mountain in Massachusetts, computed to be about 4000 feet above the sea, Watchfett in the county of Worcester, Ascutney in the state of Vermont, Monadnock in New Hampshire, and the White mountains in the same state, of which the highest summit is Mount Washington, probably between 10,000 and 11,000 feet above the ocean, and the highest land in the United States. This mountain is covered during a great part of the year with snow, and is seen in fair weather at the distance of 90 miles from the sea, and 160 from its base. New England abounds in cataracts and cascades; those of the White mountains being singularly romantic and beautiful. The principal rivers of New England are the Schoduck, Penobscot, Kennebeck, Amaricoggin, Saco, Piscataqua, Merrimack, Parkers, Charles, Taunton, Providence, Thames, Connecticut, Hoosstonuck or Stratford, Onion, La Moille, and Missisconi. The largest of these are Penobscot, Kennebeck, Merrimack, and Connecticut. The chief lakes are Champlain and Memphremagog, lying partly in Vermont and partly in New York; Winnipisogee and Umbagog in New Hampshire; Sebago, Moosehead, Willeguaguagun, and Chilmacook or Grand lake in Maine. The most important and useful harbours are those of Machias, Frenchman's bay, Wiscasset, Portland and Wells, in Maine; Piscataqua in New Hampshire; Newbury port, Salem, Marble head, Boston, Provincetown, and New Bedford, in Massachusetts Proper; Newport, Bristol, and Providence, in Rhode island; and New London, New Haven, and Black rock, in Fairfield, in Connecticut. Burlington bay is the most considerable harbour in lake Champlain, on the Vermont shore.

The soil of New England is diversified by every variety from a lean and barren sand to the richest clays and loams.

The hills are covered with a brown loam intermixed with gravel, which is favourable to the production of grafs, and in the western parts of the country, of wheat, and all other kinds of grain and fruits suited to the climate. Clayey soils, when well manured, are very productive. A rich loam, varying towards clay, is prevalent in Connecticut, and is favourable to every kind of cultivation. Sand is generally found on the plains; and the yellow pine plains, which are commonly a mixture of sand and gravel, are friendly to every production that does not require a richer soil. The white pine plains are usually covered with loam, and these, as well as some of the last-mentioned in the same condition, are uncommonly fertile. The vallies are a rich mould; and the intervals, bordering the various streams, are generally sands formed by earth deposited by the floods in the spring, and are of the richest quality.

New England, generally speaking, is better adapted for grazing than for grain, though a sufficient quantity of the latter is raised for home consumption, if we except wheat which is largely imported, particularly into Massachusetts, from the middle and southern states. Indian corn, rye, oats, barley, buck-wheat, flax and hemp, generally succeed very well. Fruits of every kind, which suit a temperate climate, may be obtained in abundance. The summer heat brings to perfection peaches, apricots, and nectarines. Orchards of apple-trees cover a considerable part of the whole country, and cyder is the common drink of the inhabitants. Pears, plums, cherries, currants, gooseberries, whortleberries, blackberries, bilberries, &c. abound. Perry is made in some parts of the country, but not in great quantities. Various species of the hickery and hazle-nuts, and chestnuts are plentifully furnished by the southern half of New England. Gardening is much improved, and its productions are daily varying and increasing. But the most important production of New England is grafs. The high and rocky ground is in many parts covered with clover, and affords excellent pasture to some of the finest cattle in the world. The quantity of butter and cheese made for exportation is very great. Considerable attention is now paid to the raising of sheep; and the wool is in a state of progressive improvement. The principal exports of New England are mackarel, salmon, cod, and other fish; whale-oil and whale-bone, timber, malts, boards, staves, hoops and shingles; horses, mules, salted beef, and pork, pot-ash, pearl-ash, flax-seed, apples, cyder, corn, butter, and cheese. New England is the most populous part of the United States; it contained, in 1790, 1,009,522 persons, and, in 1800, 1,233,011. The great body of the inhabitants consists of landholders and cultivators of the soil. As they possess in fee simple the farms which they cultivate, they are all naturally attached to their country; and the cultivation of the soil makes them robust and healthy. New England has been not unaptly denominated a nursery of men; and hence are annually transplanted into other parts of the United States, thousands of its natives. They are almost universally of English descent; and to this circumstance, as well as to the general attention that has been paid to education, it is owing that the English language has been preserved among them in so considerable a degree of purity. The New Englanders are generally tall, stout, and well-made. Their education, laws, and situation serve to inspire them with high notions of liberty, of which they are jealous, in some cases perhaps, to excess. A chief foundation of freedom in the New England states is a law, by which intestate estates descend to all the children, or other heirs, in equal proportion; and hence it happens, that the people of New England enjoy an equality of condition, that is unknown in any

other part of the world. Besides, they are frugal and industrious, and inured to habits of sobriety and temperance. Learning is more generally diffused among all ranks of people in New England than in any other part of the globe; which is owing to the excellent establishment of schools in every town. In these schools, generally supported by a public tax, are taught the elements of reading, writing, and arithmetic; and in some of the principal and more wealthy towns they are pursuing education in a higher scale, and introducing the superior branches of grammar, geography, and other sciences. Literature is also encouraged and diffused by the circulation of newspapers and periodical publications, and by the establishment of reading societies and parochial libraries. Curiosity, and a desire of information, are very prevalent in New England; and the common people, it is said, are distinguished by attention and civility to strangers. In former times the New Englanders were strict, to a degree of punctiliousness, in their observance of the sabbath; and hence, as well as from some other traits of their character, they acquired the character of a superstitious and bigotted people. But since the war, a catholic, tolerant spirit, occasioned by a more enlarged intercourse with mankind, has much increased, and is becoming universal. "If," says Dr. Morse, "they do not go beyond the proper bounds, and liberalize away all true religion, of which there is very great danger, they will counteract that strong propensity in human nature which leads men to vibrate from one extreme to its opposite." A custom still prevails, transmitted to the present race from their ancestors, of annually celebrating fasts and thanksgivings. In spring, the governors of the several New England states, Rhode island excepted, proclaim a day of fasting, humiliation, and prayer; and in autumn, after harvest, they appoint a day of public thanksgiving. Many of the women in New England are handsome. Those, who have enjoyed the advantages of a good education, and they are numerous, are genteel, easy, and agreeable in their manners, and are sprightly and sensible in their conversation. And it is a laudable practice among the females to accustom themselves at an early period to the management of domestic concerns with neatness and economy. Employment at the needle, in cookery, and at the spinning-wheel, is honourable. The women in country towns manufacture the greater part of the clothing of their families. Their linen and woollen cloths are strong and decent. Among the amusements of the people of New England is dancing, of which the young people of both sexes are extremely fond. The athletic and healthy diversions of cricket, foot-ball, quoits, wrestling, jumping, hopping, foot-races, and prison-bars, are universally practised in the country, and some of them in the most populous places, and by people of almost all ranks. Of the religion of the New Englanders, and of the provision that is made for the support of it, we shall have occasion to speak under the article UNITED STATES. We shall here merely observe, that the constitution of these states provides against the making of any law respecting an establishment of religion, or prohibiting the free exercise of it. And in the constitution of the respective states, religious liberty is a fundamental principle. Without the aid of civil power, religion is left to be supported by its own evidence, by the lives of its professors, and the almighty care of its divine author. Its public teachers are maintained by an equal tax on property, by pew-rents, monies at interest, marriage and burial fees, small glebes, land rents, and voluntary contributions. Christians profess their religion under various forms, and with different ideas of its doctrines, ordinances, and precepts. Accordingly the sects of Christians are very numerous and

various. Of these sects, those that are called Congregationalists are the most numerous. In New England there are about 1200 congregations of this denomination. Next to these in respect of number are Presbyterians. In New England there are between 40 and 50 Protestant episcopal churches.

New England owes its first settlement to religious persecution; and the inhabitants of this country are descended from those that were called Puritans in the mother-country. The first attempt to form a regular settlement in this part of America was at Sagadahock in 1607; but in the following year, the whole number of those who survived the winter returned to England. The first company, that laid the foundation of the New England states, planted themselves at Plymouth, in November, 1620; though this appellation was given to North Virginia by Capt. Smith in August 1614. The founders of the colony consisted of 101 persons. In 1640, the importation of settlers ceased, in consequence of the abatement of persecution by the change of affairs in England. At this time the number of emigrants, who had traversed the seas in 298 vessels, from the commencement of the colony, amounted to 21,200 men, women, and children, forming, perhaps, about 4000 families. In 1760, the number of inhabitants in Massachusetts bay, New Hampshire, Connecticut, and Rhode island, amounted, probably, to half a million. Morse.

ENGLANTERIA, in *Botany*. See EGLANTERIA.

ENGLECHERIE, ENGLSCHERY, or *Engleschere*, a term of great import among our ancestors, though now obsolete; properly signifying the quality of an Englishman.

If a man were privately slain or murdered, he was anciently accounted francigena (which comprehended every alien, especially the Danes) till englecherie was proved, *i. e.* till it was made to appear that he was an Englishman. Bracton, lib. iii.

The origin of the custom anciently subsisting among the Goths in Sweden and Denmark, was thus: king Canutus, having conquered England, at the request of his nobles, sent back his army into Denmark, only reserving a guard of Danes for his person; and made a law, that if any person was murdered, he should be supposed to be a Dane, if he was not proved to be an Englishman by his parents or kindred, and, in default of such proof, if the murderer was unknown, or had made his escape, the township where the man was slain should be charged to pay sixty-six marks into the exchequer: or if by reason of the poverty of the township, that sum could not be raised from thence, it was to be paid by the hundred. After this law, which was continued by William the Conqueror, for the like security to his own Normans, whenever a murder was committed, it was necessary to prove the party slain an Englishman, that the penalty of sixty-six marks might not be charged on the village. The manner of proving the person killed to be an Englishman was by two witnesses, who knew the father and mother, before the coroner, &c. This practice was abolished by statute 14 Edw. III. cap. 4. See MURDER.

ENGLESQUEVILLE, in *Geography*, a small town of France, in the department of the Lower Seine, 18 miles S.W. of Arques. There are several small towns of the same name, in the department which comprises the former province of Normandy.

ENGLISH, in a general sense, something that relates to the country or people of England. Thus we say, the English crown, English copperas, English names, English money, English measures, English weights, &c. The sweating-sickness is called by foreigners *Judor Anglicanus*, the

English sweat. (See *SUDOR-ANGLICUS*.) Dr. Cheyne calls the vapours the English malady.

ENGLISH *Borough*. See *BOROUGH*.

ENGLISH *Cape*, in *Geography*, a cape on the south coast of Newfoundland. N. lat. 46° 49'. W. long. 53° 29'.

ENGLISH *Cove*, a harbour, or bay, on the coast of New Ireland, about 3 or 4 miles from cape St. George.

ENGLISH *Drops*, *Gutta Anglicanae*. See *DROP*.

ENGLISH *Harbour*, in *Geography*, one of the best harbours in the island of Antigua, situated on the S.W., a little to the E. of Falmouth harbour. It is well fortified, and has a royal navy-yard and arsenal, with conveniences for careening ships of war. N. lat. 17° 8' 25". W. long. 61° 27' 30".

ENGLISH *Point*, a cape in the river St. Lawrence, on the coast of Canada. N. lat. 49° 40'. W. long. 61° 45'.

ENGLISH *Reach*, a reach in the straits of Magellan, about 3 leagues broad, between cape Gallant and cape Holland.

ENGLISH *Road*, a road in the island of Eooa, or Middleburgh, in the South Pacific ocean, having 25 fathoms water. S. lat. 21° 20'. W. long. 174° 34'.

ENGLISH *School of Engraving*. See *ENGRAVING*.

ENGLISH, or the ENGLISH *Tongue*, the language spoken by the people of England; and with some variation, by those of Scotland, as well as part of Ireland, and the rest of the British dominions.

The English is of Gothic, or Teutonic extraction; this was the root or stock upon which several other dialects have been since grafted, particularly the Latin and French. See *TEUTONIC*, &c.

The language anciently spoken in our island was the British, or Welsh, which was common to the Britons and Gauls; and which still subsists, in more or less purity, in the principality of Wales, the islands and Highlands of Scotland, part of Ireland, and some provinces of France, particularly Bretagne, and very lately subsisted in the county of Cornwall. (See *CORNISH Language*.) This language was the Celtic or Gaelic, which is said to be very copious and expressive, and is, probably, one of the most ancient languages in the world. It once obtained in most of the western regions of Europe: and now remains in the different dialects of the Irish, Welsh, and Erse. See *CELTS*.

As the Roman empire, extending itself towards the western parts of Europe, under Julius Cæsar, Claudius, and Domitian, came to take in Gaul and Britain, the Roman tongue became propagated therewith; all the edicts, &c. relating to the public affairs, being designedly wrote in that language.

The Latin, however, it is certain, never got so much ground, or prevailed so far in England, as in Lombardy, Spain, and the Gauls; partly on account of its great distance from Rome, and the small resort of Romans hither; and partly, because the entire reduction of the kingdom was not effected till so late as the reign of Claudius, when the empire was on the declining hand, and the new province was forced to be soon deserted by its conquerors, called to defend their territories nearer home.

Britain, thus left naked, became an easy prey to the Angli, or Anglo-Saxons, a strolling nation, from Jutland and Norway, who took an easy possession thereof about the year 450, much about the time that the Franks, another German nation, entered Gaul. The Gauls and Franks, it seems, at length came to terms; found means to unite into one nation; and thus, the ancient Gaulish, with its mixture of Latin, continued the prevailing tongue, only farther intermixed with the Francic or lingua Franca of the new inmates; but the Britons were more constant, and determined absolutely to refuse any such coalition: they had embraced Christianity,

Augustine being sent from Rome to convert them about the year 570, and their competitors were heathens; rather than admit of such an union, they therefore chose to be shut up, with their language, in the mountainous parts of Cambria or Wales.

The English Saxons, thus left absolute lords, changed every thing; their own language, a dialect of the Gothic or Teutonic, and altogether distinct from the Celtic, was now fully established, and laid the foundation of the present English tongue: and the very name of the country was henceforth to be Anglo-Saxon. (See *ANGLO-SAXON*.) The new language remained, in good measure, pure and unmixed, till the Norman invasion: the attempts of the Danes, and the neighbourhood of the Britons, indeed, wrought some lesser innovations therein; but, in the main it preserved itself; for, as to the Danes, their language was, probably, from the same root with the Saxon; and it did not long remain a distinct tongue in any part of England, but was blended with the Anglo-Saxon, and formed a particular dialect of that language.

This Dano-Saxonic dialect was principally spoken in the kingdom of Northumberland, where the Danes chiefly prevailed: that the Anglo-Saxon language was spoken in the S.E. parts of Scotland at this time is undeniable. When Edgar the Peaceable, king of England, yielded Lothian to Kenneth II. king of Scotland, A.D. 975, it was on these express conditions; that the people of that country should still be called Englishmen, be governed by the English laws, and be allowed to speak the English language.

Edward the Confessor, however, who had lived long in France, might possibly bring in a little mixture of the dialect of that country.

But William I. and his Normans, having got possession of England, an alteration was soon attempted: the conquest was not complete, unless the Conqueror's language, the French and Franco-Gallic, were introduced; and accordingly all his acts, diplomas, edicts, pleadings, and other judicial matters, were written, &c. in that tongue.

But his attempts proved unsuccessful; the number of Normans he brought over being very small in comparison of the English, with whom they were incorporated, they lost or forgot their own language, sooner than they could make any change in the English. This, however, did not hinder, but, by the endeavours of the Conqueror, abundance of French words, though many of them of Latin original, crept into the English; and many English words, by degrees, grew out of use. Hence it happened, that the English, which was spoken afterwards, and continues to be spoken now, is a mixture of the ancient Saxon and this Norman French, together with such new and foreign words as commerce and learning have in the progress of time gradually introduced. See *ANGLO-SAXON*.

Upon the whole it appears, that the Teutonic dialect is the basis of our present speech. It has been imported among us in three different forms, the Saxon, the Danish, and the Norman; all which have mingled together in our language, so that it may be supposed to exist in three different periods, viz. Anglo-Saxon, Danish-Saxon, and Norman-Saxon. The first begins with the Saxon invasion, the second with the Danish, and the third with the Norman. Some have made the properly English period to commence with Edward I., towards the close of the 13th century; others have referred it to the 14th century; and others again have thought that it ought rather to commence with Henry VIII.; as the controversies of the Reformation were in fact the cause which then abolished the Norman dialect of the court, and introduced the present common English to our worship and

## ENGLISH.

to our literature. Many of our words are also plainly derived from the Latin. But these were not introduced directly from the Latin; whereas most of them, probably, entered into our tongue through the channel of that Norman French, which William the Conqueror introduced. For, as the Romans had long been in full possession of Gaul, the language spoken in that country, when it was invaded by the Franks and Normans, was a sort of corrupted Latin, mingled with Celtic, to which was given the name of Romanish; and as the Franks and Normans did not, like the Saxons in England, expel the inhabitants, but, after their victories, mingled with them; the language of the country became a compound of the Teutonic dialect imported by these conquerors, and of the former corrupted Latin. Hence, the French language has always continued to have a very considerable affinity with the Latin; and hence, a great number of words of Latin origin, which were in use among the Normans in France, were introduced into our tongue at the conquest: to which, indeed, many have been since added, directly from the Latin, in consequence of the great diffusion of Roman literature throughout all Europe. From the influx of so many streams, or the junction of so many dissimilar parts, it naturally follows that the English, like every compounded language, must necessarily be somewhat irregular. We cannot expect from it, says Dr. Blair (*Lectures, &c.* vol. i.) that correspondence of parts, that complete analogy in structure, which may be found in those simpler languages, which have been formed in a manner within themselves, and built on one foundation. Hence, it has but small remains of conjugation or declension; and its syntax is narrow, as there are few marks in the words themselves that can shew their relation to each other, or, in the grammatical style, point out either their concordance, or their government, in the sentence. Our words having been brought to us from several different regions, straggle, if we may so speak, asunder from each other; and do not coalesce so naturally in the structure of a sentence, as the words in the Greek and Roman tongues. But these disadvantages, if they be such, of a compound language, are balanced by other advantages that attend it; particularly by the number and variety of words with which such a language is likely to be enriched.

As to the origin and etymology of many of our words, Dr. Wallis lays it down, that such words of German original as we have, in common with the French, are to be reckoned as our own, rather than as words borrowed from them; and that the old Gaulish words, common to the French and the Welsh, which are found in our language, have been likewise taken from the Welsh, rather than from the French. Hence, also, the same author accounts why the names of the divers sorts of cattle are Saxon; as ox, cow, calf, sheep, hog, boar, deer, &c. and yet that their flesh, when prepared for food, is French; as beef, veal, mutton, pork, brawn, venison, &c. the Norman soldiers not concerning themselves with pastures, parks, and the like places, where such creatures are fed and kept, so much as with markets, kitchens, feasts, and entertainments, where the food was either prepared, sold, or eaten.

Under Henry II., Dr. Swift observes, the French made a still greater progress; because of the large territories he possessed on that continent, both from his father and his wife, which occasioned frequent journeys thither, with numerous retinues, &c. And for some centuries after, there was a constant intercourse between France and England, by the dominions we possessed there, and the conquests we made; so that the language, two or three hundred years ago, seems to have had much more French than at present.

Besides this alteration from the conquerors, the language in process of time underwent several others; and at length came to have numerous words and phrases of foreign dialects ingrafted into it, in lieu of the ancient Saxon; particularly, by means of negotiations and commerce with other nations; by the marriages of royal families; by the affectation of many writers, in most ages, who are fond of coining new words, and altering the usual forms of speech, for the greater delicacy; and, by the necessity of framing or borrowing new words, according as new things and inventions turn up: and by such means was the old Anglo-Saxon converted into the present English tongue. See **ANGLO-SAXON**.

Having traced the rise and progress of our language historically, we think it may be no inconsiderable amusement to represent by actual examples the several successive changes and stages it has passed through, to arrive at its present perfection: in order to which, we shall make use of the collections of the ingenious Mr. Greenwood.

From the Saxon invasion, we have no memorial extant of the language for 250 years: the oldest Saxon writing in being is a gloss on the evangelists, written in the year 700, by Eadfride, bishop of Holy Island; in which the three first articles of the Lord's Prayer run thus:

"Uren Fader thic arth in heofnas, sic gehalgud thin noma, to cymeth thin ryc. Sic thin willa sue is in heofnas, and in eorþo," &c. See **ANGLO-SAXON**.

Two hundred years after, in the year 900, the same was rendered thus:

"Thu ure Fader the eart on heofinum, si thin nama gehalgod; cum thin ric. Si thin willa on eorþan swa, swa on heofinum."

In the following age it was turned thus in the Saxon Homilies, said to be translated by king Alfred:

"Fæder ure thu the earth on heofenum, si thin nama gehalgod, to be cume thin rice, gewurthe thin willa on eorþan swa, swa on heofinum," &c.

About the year 1160, under Henry II., near which period the Saxon began to assume a form in which the beginning of the present English may be discovered; it was thus rendered by pope Adrian, an Englishman, in rhyme:

"Ure Fader in heaven rich,  
Thy name be hayled ever lich,  
Thou bring us thy michell blisse:  
Als hit in heaven y-doe  
Evar in yearth beene it also," &c.

About 100 years after, in the time of Henry III., it was translated thus:

"Fadir that art in heaven blisse,  
Thin helge nam it wurth the blifs,  
Cumen & mot thy kingdom,  
Thin holy will be it all don,  
In heaven and in erdh also," &c.

Two hundred years after, under Henry VI., it was rendered thus:

"Our Fadir that art in hevenes, halewid be the name,  
thi kingdom come to thee, be thi will don in eerthe, as in hevene."

Dr. Hickes furnishes an extraordinary specimen of the English, as spoken in the year 1385, in his *Theaur. Liter. Septent.* which we shall the rather amuse the reader with, as it is on this very subject, the English tongue; and contains not only the history, but the reason of the changes and differences therein:

"As it is knowe how meny maner peple beeth in this lond; there beeth also so many dyvers longages and tonges. Notheles Walsche men and Scots that beeth nought medled  
with

with other nations, holdeth wel nyh hir first longage and speche: but yif the Scottes that were sometime confederat and woned with the Pictes drawe somewhat after hir speche; but the Flemynge that woneth in the weste side of Wales, haveth left her strange spech, and speketh Saxonliche now. Also English men, they had from the bygynnyng three maner speche; northerne, sowerne, and middel speche in the middel of the londe, as they come of three maner of peple of Germania: notheless by comyxtion and mellynge first with Danes, and afterwards with Normans, in meny the contrary longage is apayred [corrupted.] This apayryng of the burthe of the tunge is bycause of tweie thynges, oon is for children in scole agens the usage and maner of all other nations, beeth compelled for to leve hire own longage, and for to construe hir lessons and here thynges in French, and so they haveth sethe Normans come first into Engelond. Also gentlemen children beeth taught to speke Frenche from the tyme that they beeth rokked in here cradel, and kunne speke and play with a childes broche; and uplondische men will linke hymself to gentilmen, and fondeth with great beynesse for to speake Frenche to be told of. Hit seemeth a greet wonder how English men and her own longage and tonge, is so dyverse of foun in this oon ilond; and the longage of Normandie is comlynge of another lond, and hath oon manner foun amonge alle men that speketh hit arigt in Engelond. Also of the foresaid Saxon tonge that is deled [divided] a three, and is abide scarceliche with few uplondische men, is greet wonder. For men of the est, with men of the west, is, as it were, under the same partie of hevne acordeth more in fownygne of spech, than men of the north, with men of the south. Therefore it is that Mercii, that beeth men of myddel Engelond, as it were parteners of the endes, understondeth better the side longages northerne and souterne, than northerne and souterne understondeth either other. All the longage of the Northumbers, and specialliche at York, is so scharp, slitting and frotyng, and unschape, that we souterne men may that longage unneth understonde. I trow that that is by cause that they beeth nyh to strange men and nations, that speketh strongliche, and also bycause that the kinges of Engelond wonneth alwey fer from that cuntry," &c.

The first of our authors, who can properly be said to have written English, was sir John Gower, who, in his Confession of a Lover, calls Chaucer his disciple.

How the English stood about the year 1400, may be seen in Chaucer, who refined and improved it very considerably; though he is charged with the affectation of mixing too many French and Latin words with his English, and by that means, with too much altering and corrupting the primitive language.

In the year 1537, the Lord's Prayer was printed according to the following version:

"O oure Father which arte in heven, halowed be thy name: let thy kingdome come, thy will be fulfilled as well in erth as it is in heven," &c.

Where the reader will observe the diction almost brought to the present standard; the variations being principally in the orthography. See an historical view of the progress of the English language, with specimens at different periods, from the age of Alfred to that of Elizabeth, in the Introduction to Dr. Johnson's English Dictionary, vol. i. fol:

Spencer, who lived in the same age, contributed not a little to the improvement and refining of the tongue: he threw aside abundance of the outlandish ornaments, and wrote a purer English, yet with more elegance and variety than had been known before. He was succeeded by

Shakespeare, Ben. Johnson, lord Bacon, Milton, Cowley, Waller, Tillotson, Dryden, Addison, and Pope, &c. whose works are in every body's hands; and by whom the language has been transmitted to us under all its present advantages.

The perfections ascribed to the English, and also in a degree superior to any of the modern tongues, are, 1. That it is very strong and significant; to which our finely compounded words, formed on the model of the Greeks, do not a little contribute.

This may also be partly ascribed to the national character of the people who speak it, from which language is apt to receive its predominant tincture. Thus, the gravity and thoughtfulness, as well as the strength and energy, of the English, and also the gaiety and vivacity of the French, are sufficiently impressed on their native tongues. However, though the English language possesses distinguishing strength and energy, it is naturally prolix, on account of the great number of particles and auxiliary verbs, which in the use of it we are obliged constantly to employ; and this prolixity must, in some degree, enfeeble it. We seldom can express so much by one word as was done by the verbs, and by the nouns, in the Greek and Roman languages. Our style is less compact; our conceptions being spread out among more words, and split, as it were, into more parts, make a fainter impression when we utter them. Notwithstanding this defect, as our language abounds in terms for expressing all the strong emotions of the mind, and we have the liberty, in a greater degree than most nations, of compounding words, it may be esteemed to possess considerable force of expression; more especially when we compare it with the other modern tongues, though much below the ancient. The style of Milton alone, both in poetry and prose, affords sufficient evidence, that the English tongue is far from being destitute of nerves and energy.

2. The English language is copious; of which Mr. Greenwood gives us instances in the word striking; which we have above thirty different synonymous expressions for; as to *smite, bang, beat, bash, buffet, cuff, hit, thump, thwack, slap, rap, tap, kick, spurn, box, yerke, pummel, punch, &c.* and the word *anger*, for which he enumerates above forty. So we say *to seeth* or *boil* flesh, *stew* prunes, *poche* eggs, *coddle* apples, *bake* bread; for which expressions, *to seeth, stew, poche, coddle, and bake*, the Latins, with all the boasted copia of the tongue, have only one word, *coquere*; and the French, as much as they abound with terms of cookery, not many more; the word *cuire* serving indifferently for *seething, boiling, baking, stewing, and coddling*.

Indeed, few languages are more copious than the English. In all grave subjects especially, historical, critical, political, and moral, no writer can justly complain of the barrenness of our tongue. We are also rich in the language of poetry. Our poetical style differs widely from prose, not in point of numbers only, but in the very words themselves; which shews what a stock and compass of words we may select and employ, suited to different occasions. In this respect we are infinitely superior to the French, whose poetical language, if it were not distinguished by rhyme, would not be known to differ from their ordinary prose. It is chiefly, however, on grave subjects, and with respect to the stronger emotions of the mind, that our language displays its power of expression. But, in describing the more delicate sentiments and emotions, our tongue is not so fertile; and we must acknowledge its inferiority to the French. This is, perhaps, the happiest language for conversation in the known world; but, on the higher subjects of composition, it is much excelled by the English.

3. The English language is not destitute of flexibility. This power of accommodation to different styles and manners, so as to be either grave and strong, or easy and flowing, or tender and gentle, or pompous and magnificent, as an author's genius prompts or occasions require, is a quality of great importance both in speaking and writing. This property of a language seems to depend upon three things: its copiousness; the different arrangements of which its words are susceptible; and the variety and beauty of the sound of those words, so as to correspond to many different subjects. The Greek possessed this property in a super-eminent degree; the Latin was, in this respect, inferior to it; and among the modern tongues, the Italian possesses flexibility in a greater degree than the French; and though our language has less of it than the Italian, it possesses a considerable degree of this quality. If any one will consider the diversity of style which appears in some of our classics; that great difference of manner, for instance, which is marked by the style of lord Shaftesbury, and that of dean Swift; he will perceive, in our tongue, such a circle of expression, such a power of accommodation to the different taste of writers, as redounds not a little to its honour.

4. Some have challenged to the English language the praise of being musical and harmonious; and in this respect Mr. Dennis makes no scruple to assert it superior even to the French. This, which some may think strange, he proves hence, that we have blank verse which is harmonious by mere force of numbers and quantity; whereas the French have long ago desisted from all pretensions to poetical numbers, without the assistance of rhyme.

It may be added on this last head, from Mr. Wellstead, that the English has many measures, the iambic and trochee, for instance, in common with the Greek and Latin; an advantage arising from the variation of the accent; and that rhyme is peculiarly natural to it, varying itself to the ear with excessive sweetness; not to mention the cæsuras, pauses, transpositions, and numberless other graces, which the English versification is capable of, probably beyond every other living language.

The English has, indeed, been reproached on account of its deficiency in harmony of sound; but the charge has been extended too far. The melody of our versification, and the power which our language possesses of supporting poetical numbers, without any assistance from rhyme, afford sufficient proof that our language is far from being unmusical. Next to the Italian, our verse is the most diversified and harmonious of any of the modern dialects; and far exceeds the French in variety, sweetness, and melody. Mr. Sheridan has shewn, in his Lectures, that we abound more in vowel and diphthong sounds than most languages; and these, too, so divided into long and short, as to afford a proper diversity in the quantity of our syllables. Our consonants, he observes, though they appear crowded to the eye on paper, often form combinations not disagreeable to the ear in pronouncing; and, in particular, the objection which has been made to the frequent recurrence of the hissing consonant *s* in our language is unjust and ill-founded: for this letter frequently loses the hissing sound, especially in the final syllables, and is transformed into a *z*, affording a sound on which the ear can rest with pleasure. After all, it must be allowed, that strength and expressiveness, more than grace and melody, are the distinguishing properties of the English tongue. It is a remarkable peculiarity of English pronunciation, that the accent is thrown farther back, or nearer the beginning of a word, than is done by any other nation; and the general effect of this practice of hastening the accent is to give a brisk and a spirited, but at

the same time a rapid and hurried, and not very musical, tone to the whole pronunciation of a people.

5. The English tongue is, without doubt, the most simple in its form and construction of all the European dialects. It is free from all intricacy of cases, declensions, moods, and tenses. The words are subject to fewer variations from their original form than those of any other language. Its substantives have no distinction of gender, except what nature has made, and but one variation in case. Its adjectives admit of no change at all, except what expresses the degree of comparison. Its verbs, instead of running through all the varieties of ancient conjugation, suffer no more than four or five changes in inflection. By the help of a few prepositions and auxiliary verbs, all the purposes of significance in meaning are accomplished; while the words commonly preserve their form unchanged; which structure, though it has its disadvantages in point of elegance, brevity, and force, contributes to facility. However, bishop Lowth has observed in the Preface to his Grammar, that the simplicity and facility of our language occasion its being frequently written and spoken with less accuracy. See GRAMMAR, LANGUAGE, STYLE, SYNTAX, &c.

Some object to the English, that it consists too much of monosyllables; which others represent as an excellence, because it argues a greater antiquity, if what Salmastius says be true: *Certum quippe est, linguas omnes, quæ monosyllabis constant, cæteris esse antiquiores;*" he adds, that the "ancient Greek abounded herein, as appears from the ancient poets, and such as affected antiquity." *De Re Hellenist.*

But we have a farther advantage from our monosyllables, *viz.* "conciseness;" as we are hereby enabled to express more matter in the same compass of letters than any other modern tongue. The only thing we suffer by it, is, something in point of softness and numbers; and yet we have verses composed wholly of monosyllables, that do not want harmony; as that of Creech,

"Nor could the world have borne so fierce a flame."

Others object to our language, that it does not equal the softness, the delicacy, of the more southern languages, of France, Spain, and Italy. It seems to retain somewhat of the Gothic roughness of the people who framed and introduced it; the soil and climate it was planted in, not tending much to mellow and refine it.

To this purpose does Dr. Swift speak, who accounts for the effect hence, that the Latin tongue was never in its purity in our island; and besides, it was removed, in its imperfect state, before it could have time to incorporate with the language of the country, and subdue and soften it, as it did in the other provinces of France and Spain, &c. But it is to be observed, that, upon the whole, this, supposing it true, does not lie as an objection against the language, but the people: our manners are also less polished than some of our neighbours; we are not yet arrived at that pitch of moleste, of delicateffe, of soupléffe, which we censure in them; and it is but just our language correspond with the rest of our character.

Mr. Wellstead is of opinion, that the English language is not capable of a much greater perfection than it has already attained. We have trafficked, he observes, with every country for the enriching of it; the ancients and moderns have both contributed to give it splendour and magnificence; the fairest cyons that could be had from the gardens of France and Italy, have been grafted on our old stocks, to refine the savageness of the breed; we have laid

aside most of our harsh, antique words, and retained few but those of good and sound energy: the most beautiful polish is at length given to our tongue that it will bear, without destroying and altering the very basis and ground work of it; its Teutonic rust is worn away, and little or nothing is wanting either of copiousness or harmony. He goes on to argue the maturity and perfection of the English, from another very extrinsic principle, *viz.* by comparing the time and circumstances of the improvements made since the first refiners of it; with those of the Greek, Latin, French, and other tongues that confessedly have risen to their height.

Every civilized nation, that author thinks, has its classical age; and he suggests, that the English are not far from it. So that what remains to be done for the English tongue, should not be to advance, but to fix it where it is, and prevent its declining. There is, in effect, a point of perfection, which when a language has once arrived at, it cannot exceed, though it may degenerate from it; and thus it happened to the two finest languages that the world has known.

It may seem odd to talk of fixing so unstable a thing as language: the Greek liturgies of St. Basil, and St. Chrysostom, still used in that church, the one for solemn, the other for common days, have been a long time unintelligible to the people; so much has the vulgar Greek degenerated from its original purity! Polybius testifies, that the articles of truce between the Romans and Carthaginians could scarcely be understood by the most learned Roman antiquaries, three hundred and fifty years after the time in which they were made. In effect, from the days of Romulus to those of Julius Cæsar, the Latin was perpetually changing; and what was written three hundred years before Tully, was as unintelligible in his time as the English and French of the same period are now; and these two have changed as much since William the Conqueror, in about eight hundred years, as the Latin appears to have done in a like term.

Whether our language will decline as fast as the Roman did, may admit of some doubt; there being many circumstances in the affairs of the nation, which contributed to that speedy corruption, that may not, in all probability, find place among us. The French for about two centuries past, has been polishing as much as it will bear; and it appears to be now declining, by the natural inconstancy of that people, and the affectation of some late authors, to introduce cant words, which is the most ruinous corruption in any language. But without some such consideration there does not seem any absolute necessity, why a language should be perpetually changing.

We find examples to the contrary: from Homer to Plutarch, are above a thousand years; and so long, at least, Dr. Swift thinks, we may allow the purity of the Greek; the Grecians spread their colonies round all the coasts and islands of Asia Minor, and the Ægean sea, where the language was preserved entire for many ages after they themselves became provinces to Rome, and were over-run by the barbarous nations. The Chinese have books in their language above two thousand years old; neither have the frequent conquests of the Tartars been able to alter it. And the German, Spanish, and Italian, have admitted few or no changes for some ages past.

On such considerations, that author moved the then prime minister, the earl of Oxford, to establish a society, or academy, for the settling, and ascertaining, the purity of our tongue; to set a mark on the improprieties which custom has made familiar, to throw out vicious phrases and words, to correct others, and perhaps retrieve some others now grown obsolete, and to adjust the orthography, pointing, &c.

Without some such means, he complains that the fame any writer can expect will be so short and scanty, as by no means to be a sufficient motive to call forth, and engage a man to exert his genius. Our language is chiefly confined to these two islands; and it is hard our authors' fame should be limited in time as well as place. Were it not for the Bible and Common-Prayer, we should hardly have been able to understand any thing written about two centuries ago.

It is a melancholy reflection, that Petrarch still speaks good Italian; whereas Chaucer, who lived an hundred years later, is not to be understood by an English reader without a Saxon and French glossary. And what security has Dryden himself, while things continue on their present footing, that he shall not, in a like space of time, become as obsolete as Chaucer is?

Grammars and dictionaries, with whatever care and judgment they are composed, will prove but a feeble stay to a fleeting language, unless they have some extraordinary sanction and authority. And, what is to be lamented, such writings have contributed to the corruption almost as much as the perfection of our tongue.

Dr. Gill, Ben Johnson, and Hexham, it is certain, by forcing the English tongue to the Latin method, have clogged and perplexed it with abundance of useless precepts concerning cases, genders, and declension of nouns, tenses, moods, and conjugations of verbs, and other things which our language has nothing to do with. Nor have even Dr. Wallis, Greenwood, &c. though sensible of the fault in those others, been able wholly to keep clear of it themselves. See *STYLE*.

*ENGLISH Town*, in *Geography*, a small village in the north-western part of Monmouth county, in New Jersey, on the road from Princeton to Shrewsbury; 21 miles from the former, and six W. of Monmouth court-house.

*ENGLISH Turn*. See *DETOUR Des Anglois*.

*ENGLSTAIN*, a town of Germany, in the archduchy of Austria; six miles N.W. of Zwettl.

*ENGONASIS*, *Ἐγωνασις*, in *Astronomy*, Hercules; one of the northern constellations. See *HERCULES*.

*ENGOUTED*, in *Falconry*, is said of a hawk's feathers, when they have black spots in them.

*ENGRAFTING*. See *GRAFTING*.

*ENGRAILED*, or *INGRAILED*, in *Heraldry*, (from the French *grêle*, hail) is when a thing is represented with its edges ragged, or notched, semi-circularly, as if broken by something falling on it. See *INDENTED* and *INVECTED*.

Spelman expresses it in Latin by *imbricatus*; others by *ingrediatus*; and others by *striatus*.

*ENGRAPPLE*. This is a device in use principally in *Naval Warfare*, where it is intended to retain an enemy's vessel in some particular position, especially for the purpose of boarding. When an opportunity may offer of grappling across a ship's bows, or stern, so as to allow raking her fore and aft, the battle is usually but of short duration; it being almost impossible for a crew to stand to their guns while subject to so destructive a fire. Generally we find, that when a commander is intent on boarding his opponent, he has his yard-arms supplied with small grapnails, which being lowered down at pleasure, among the enemy's rigging, hook therein, and thus prevent her from retiring to avoid the boarders. Sometimes poles, having long bars at their ends, are used for the same purpose; these are chiefly managed by the forecattle-men, and have their butts lashed to the *davit*, or to the *cat-head*. Whatever contrivance may be in use for engrappling, it is expedient that the implement be every where sufficiently solid or firm to retain its hold,  
and

and to resist the hatchet, otherwise the enemy would speedily cut them away: thus, all grap-nails should be suspended by means of chains, passed through blocks at the yard-arms; nor should the tackle, by which they are acted upon, be hauled tight until the points of the grap-nails may be firmly hooked among the shroud-hawfers, or some such substantial part of the enemy's rigging, which he could not, with safety to his masts or yards, cut away. Where it is practicable, a very strong chain should be passed round the whole of the shroud-hawfers of that mast, respectively, opposite which the vessel is engrappled; or, if that be too hazardous, the chain-plates may be secured in a similar manner. It is evident, that were the former to be all included, the enemy must cut away every support on that side his mast, before he could extricate himself: in the latter instance, as the chain-plates are of iron, and very substantial, nothing but the chain, whereby they are embraced, giving way, could afford the means of separation.

Sometimes ships become fortuitously engrappled, by the flukes of their anchors hooking among the rigging of the vessels opposed to them: this, however, is seldom permanent; for as the engrappling arises from accident, so does a lift, or heave of the sea, ordinarily set the parties at liberty, either by tearing away whatever hitches upon the fluke, or by causing the latter to unhook itself. Where the sea runs high, this is often the case; exposing both vessels to the most imminent danger, and always causing considerable damage. Hence, it should ever be considered by a commander, how far the safety of his ship may become questionable in the attempt to approach his opponent, when there is much swell. The practice of engrappling is, indeed, but rarely resorted to in ships of the line, or even by frigates; but is extremely common among privateers abounding in men, and intent upon bringing an engagement to a very speedy issue, so as to save their hulls and rigging from such damages as might compel them to seek a port wherein to re-fit.

**ENGRAVER**, one who practises the art of engraving. See **ENGRAVING**.

**ENGRAVER'S Act**, the act for securing the copy-right of engraved prints. That engravers might enjoy the fair advantages arising from the exercise of their own talents, and that the public at large might in due time succeed to such advantages, an act of parliament was passed in the 8th year of Geo. II., "for the encouragement of the arts of designing, engraving, and etching historical and other prints, by vesting the properties thereof in the inventors and engravers, during a time therein mentioned."

After thus vesting the property for the term of *fourteen* years, to commence from *the day* of publication, it enacts that the name of the proprietor shall be engraved on each plate; "and any printfeller, or other person, who shall engrave, etch, or in any other manner copy, and sell, or cause to be engraved, etched, or copied and sold, in the whole or in part by varying, adding to or diminishing from the main design, or shall print, reprint, or import for sale any such print or prints, "without the consent of the proprietor first had and obtained in writing," signed by him in the presence of two credible witnesses, or knowing the same to be so printed, &c. without consent of the proprietor, shall publish, sell, or expose to sale, then such offender "shall forfeit the plate or plates" on which such print or prints are or shall be copied, and all and every sheet or sheets (being part of or whereon such print or prints are or shall be so copied or printed) "to the proprietor or proprietors of such original print or prints," who shall forthwith destroy the same. And further, that every such offender shall forfeit five shillings for every print which shall be found in his custody, either

printed and published, or exposed to sale; one moiety to the king and the other to the informer.—*Note*, These penalties do not extend to purchasers of plates from the original proprietors (s. 2.): and actions for offending against this act must be brought within three months (s. 3.)

The act of 7 Geo. III. c. 38. after reciting that the preceding act had been found ineffectual, enacts, that the original inventors, designers, or engravers of any print, "map, chart, or plan, or any other print whatsoever," taken from any picture, drawing, or sculpture, are entitled to the benefit and protection of the recited and present acts; and by (sect. 7,) *extends* the rights intended to be secured by this and the former act to the term of *twenty-eight* years.

A subsequent act (passed in the 17th of Geo. III.) states, that the former acts have not answered the purposes for which they were intended, and that it is necessary for the encouragement of artists, that further provisions shall be made. It therefore enacts, that if any engraver, etcher, printfeller, or other person, shall, within the time limited by the aforesaid acts, engrave or etch, or cause, or procure to be engraved or etched, or worked, in "mezzotinto, or chiaro-scuro, or otherwise," copy; or who shall print, re-print, or import for sale, any copy of any historical print, or any portrait, conversation, landscape, or architecture, map, chart, or plan, or any other print whatsoever, which hath, or have been, or shall be engraved, etched, drawn, or designed "in any part of Great Britain," without the express consent of the proprietors first had and obtained in writing, then every such proprietor shall and may in a special action on the case to be brought against the offending party, recover *such* damages as a jury on the trial of such action, upon the execution of a writ of enquiry thereon, "shall give or assess," together with "double costs of suit."

The following are the most important cases which have subsequently occurred, and which are introduced to shew the legal construction which has been put upon the aforesaid act of parliament, by magistrates of high authority.

In the sittings after Hilary term, 25 Geo. III. before lord chief justice Mansfield, Sayer brought an action against Moore for pirating sea charts. The charts which had been copied were four in number, which Moore had made into one large map. It appeared in evidence that the defendant had taken the body of his publication from that of the plaintiff; and that the plaintiff had originally been at great expence in procuring materials for these maps; but it was also proved that the defendant had made many material alterations and improvements thereupon. Lord Mansfield's address to the jury upon this occasion is remarkable and important. "The rule of decision in this case, he observed, is a matter of great consequence to the country: in deciding it we must take care to guard against two extremes equally prejudicial; the one, that men of ability who have employed their time for the service of the community, may not be deprived of their just merits, and the reward of their ingenuity and labour: the other, that the world may not be deprived of improvement, nor the progress of the arts be retarded: the act that secures copy-right to authors, guards against the piracy of the words and sentiments; but it does not prohibit writing upon the same subject, as in the cases of histories and dictionaries: in the first a man may give a relation of the same fact, and in the same order of time; in the latter an interpretation is given of the identical words: in all these cases, the question of fact to come before a jury, is whether the alteration be colourable or not; there must be such a similitude as to make it probable and reasonable to suppose that one is a transcript of the other; so in the case

of prints, no doubt different men may take different engravings from the same picture. The same principle holds with regard to charts: whoever has it in his intention to publish a chart, may take advantage of all prior publications; there is no monopoly of the subject here, any more than in the other instances, but upon any question of this nature the jury will decide whether it be a servile imitation or not. If an erroneous chart be made, God forbid it should not be corrected, since it thereby becomes more serviceable and useful for the purposes to which it is applied: but here you are told that there are various and very material alterations: the defendant therefore has been correcting errors, and not servilely copying. If you think so, you will find for the defendant; if you think it a mere servile imitation, and pirated from the other, you will find for the plaintiff." [Verdict for defendant.] No action therefore lies in future for publishing sea charts on an improved and more useful principle, even though many of the lines should be copied from older charts.

In Easter term, 10 Geo. III. Wil. 60. Sayer lost his action against Dicey for copying and selling a print, because though the year of our Lord, wherein the original plate was published was engraved thereon, the day of the month was not.

In Michaelmas term, 33 Geo. III. 5 T. R. 41. an action was brought against Symonds and others, for pirating a portrait of the countess of Huntingdon. Bowyer was the original proprietor, and had assigned his right through Fittler to Thompson, by whom the action was maintained. On becoming possessed of the plate, Thompson had inserted his own name in the inscription instead of Bowyer's, "preserving the original date" of 26th day of August, 1790; but the objection started on this ground was over-ruled by the court, and the plaintiff obtained a verdict and 10*l.* damages.

ENGRAVING, ENGLISH, *Origin and Progress of.* In England, the art of engraving has gradually arisen from its rude mechanical practice by our British ancestors. It may be said to be indigenous to our soil. Roman and Saxon improvements have from time to time been engrafted; and more recently, shoots from the engraving of Germany, Italy, and France, have also been engrafted by the enterprise of individuals, not by the wisdom or authority of the state, on the original stock. It will probably excite the surprise of posterity, that this art has hitherto been cultivated, (if such might be called cultivation,) in Great Britain in no other way, though Great Britain be the chosen seat of modern commerce; and engraving, being in its nature the most commercial of those arts which administer to calm and elegant enjoyment, affords the most efficient means of diffusing through the world a just and general taste in the fine arts, and, consequently, in those numerous branches of manufacture which are derived from, and sustained by, those arts.

That it was rudely practised in this island from a very early period, may be seen by the remains of instruments of war, and other antiquities which have been found in the Celtic and Saxon tumuli; these, as is observed by that intelligent artist and antiquary, the late Mr. Strutt, frequently bear marks of the graver, or of some tool which cannot have been very dissimilar; and the numerous coins of Cunobelin must satisfy every inquirer of the early British existence of this species of engraving, an art which was probably introduced from Rome during the reign of that prince.

The art of die-engraving could not have existed alone; it implies the existence of other modes of ingenuity; and, with the use of money, must have spread the ameliorating influence of art. But all rising ingenuity, and even this mode of engraving, appears to have sunk under the Roman and

Danish ravages, which soon succeeded. Excepting these coins, those of Carausius, and a few others of less certain date, and the war implements mentioned above, faint indeed are the traces of British engraving, until the time of Alfred the Great.

"Under the protection of that excellent monarch," says Strutt, "the arts begun to manifest themselves in a superior degree. He not only encouraged such artists as were in England at the time, but invited others from abroad; and the works of the Anglo-Saxon goldsmiths, who were the principal engravers of that day, were held in the highest esteem upon the continent as well as in their native country. The caskets which they made for the preservation of the relics of saints, and other pious purposes, were ornamented with precious stones and engravings in so excellent a style, as to excite the admiration of *all who saw them.*" Wonder is the concomitant of ignorance. There is, however, yet preserved in the Museum at Oxford a very valuable jewel of gold, adorned with enamelling, and a kind of fillagree work, in the midst of which is seen the half figure of a man, which is supposed by Hickee and Wootton to represent Jesus Christ, and conjectured by Strutt to be rather intended for St. Cuthbert. The back of this curious remnant of antiquity is ornamented with engraved foliage and flowers. From the unquestionable testimony of its own legend, this jewel is known to have been made at the command of Alfred the Great, and was one of the very few articles he could have carried with him when he retreated to the isle of Athelney; where it has since been found.

Archbishop Dunstan is said to have worked in the precious metals, frequently adorning his works with images and letters which he engraved thereon. Osbern (his biographer) calls him the first of engravers; but it has been emphatically observed, that he who could add the title of *Saint* to the name of Dunstan, would not hesitate to call him a Raphael in painting, or an Audran in engraving; and the specimen of his drawing, which is still preserved in the Bodleian library, leaves us little to regret in the entire loss of his engravings.

The engraving of Dunstan and his contemporary *workmen*, was doubtless the degenerate issue of the art which the patronage of Alfred had called forth. In the tempest of war, and the night of ignorance and superstition that succeeded, scarcely a glimmering of its light was seen. The mingled work of the engraver, chaser, enameller, and goldsmith, which is seen in Alfred's jewel, entirely disappeared, but die-engraving, as it afforded the means of issuing money, became to the Anglo-Saxon princes an art of necessity, because inseparable from the existing system of government and polity; and hence, while other arts pined and perished, it was enabled to survive the inclemency of those barbarous ages, and to preserve and transmit to better times the art of the engraver.

Laws of Athelstan and Canute, appointing the number of minters who shall reside in their principal towns, and for the punishment of those who shall dare to adulterate the coinage of the realm, are still extant, and may be read in Thwaite's observations on Anglo-Saxon and Anglo-Danish Coins.

It may be presumed, that the art of die-engraving, and the weak tenures by which landed property was previously held, gave rise to the engraving and the use of seals. Before their introduction, Ingulphus expressly says, that lands were sometimes disposed of by word of mouth; sometimes by laying a turf of the land granted with religious solemnity on the holy altar; and in other instances the lord gave to the tenant a sword, bow, helmet, arrow, or drinking-horn

to certify the transfer; a drinking-horn is mentioned by Lewis as being in the possession of a Mr. Pyfsey of Berkshire, on which was engraven, "I king Knoute (Canute) have given thee this horn to hold thy land by."

In corroboration of the idea that the numismatic process suggested both the manner of engraving and of *using* seals, we may mention that the matrices of ancient English seals, of which some few are yet remaining, are formed with the same kind of cutting and punching implements which were used by the die-engraver; they were of brass, as were probably the dies of that period, and from that time to the present, metal seals have continued to be executed with the same implements used in the same manner, or with no other variations than have been produced by the gradual improvement of society operating on the peculiarities of individual talent: also (see SEAL-ENGRAVING,) that they were at first impressed as money is coined, namely, by a forcible blow, and that *lead* received the impression; and from the testimony of Ingulphus it further appears, that seals were by no means common in England before his time; he says that, "the Normans, disliking the English manner of ratifying their chirographs (or charters), ordered them to be confirmed by impressions on *wax* from the special seals of the parties concerned. The only seal in England that is known to have been impressed on wax before this period, is that of Edward the Confessor; but as this prince is known to have received his education in Normandy, the singularity is accounted for.

From this time the use and sacredness of seals went on increasing in the public estimation, so that before the lapse of a century, their devices, forms, and sizes, appropriated to the different ranks in society, were gradually settled. Even the etiquette of sealing on different coloured waxes, was ascertained with sufficient scrupulosity.

An impression from the seal of Anselm, the primate, has been copied, and is introduced (see *Pl. of British Engravings*, fig. 2.) from which some idea may be formed of the Anglo-Norman style of design and engraving, as compared with what had preceded it. The archbishop has lost his head, and has probably been decapitated in effigy, on account of his cropped hair, and by some of those resentful partizans of the long and curled locks, which were fashionable at the court of William Rufus. Against long hair, Anselm had preached with some apparent success, and with a vehemence which is highly extolled by Eadmer, his companion and secretary; but it has been observed, that though the clergy at that time could overturn thrones, and had authority sufficient to send above a million of men on *their* errand, to the deserts of Asia, they could not prevail against certain fashions.

It appears, that some argillaceous substance, apparently pipe clay, has in this instance been mixed with the wax of the seal; which has afterwards been painted either with a view to its better preservation, or to give the true tint of the rank of a Norman archbishop. The small folded parchment to which it is appendant, or rather which depends from it (see the engraving) is a grant of church land. The prolixity of modern legal forms might blush before its brevity.

About, or soon after, the time now under our observation, a new species of engraving, more simple in its nature than those which had preceded it, was either introduced into or invented in England; of which there is scarcely an old country church of any consequence, but affords some curious specimens, and England more than any other nation in Europe. The brass plates on our old sepulchral monuments are executed entirely with the graver; the shadows, where

shadowing is attempted, being expressed by lines (or strokes,) strengthened in proportion to the required depth of shade, and occasionally crossed with other lines a second, and in some instances a third time, precisely in the same manner as a copper plate is engraven that is intended for printing. On other occasions a mere outline only has been cut.

These engraved effigies are often found cemented on those horizontal tomb-stones, which form part of the pavement within the churches, where the feet of the congregation, which kept the lights bright by friction, filled the incisions with dust, and thus darkened the shades; very neat or exquisite workmanship was not therefore aimed at, and is not to be expected; yet some of these engravings bear no small evidence of the abilities of those by whom they were performed, and considering the dark period during which they were executed, are entitled to more praise than many engravings which have been subsequently produced. The engraver's style of drawing the human figure differs little from that of the contemporary illuminators of missals, and though the hands, feet, and other nudities are rarely tolerable, the stiffness of the draperies does in many instances bear considerable resemblance to the tissued and embroidered vestments of the entombed abbots, and other dignitaries of the early Catholic church; while the faces occasionally display attempts not altogether successful, as it should seem, at individual portraiture.

That which has been selected as a specimen of this mode of engraving, is from the tomb of William de Fulbourn, in Fulbourn church, Cambridgeshire, and is copied, with the permission of the Messrs. Lyfons, from their *Magna Britannia*. William de Fulbourn was appointed a baron of the exchequer in the year 1328, and is here represented (see the *Plate of English Engravings*, fig. 3.) "with the effigies of an ecclesiastic in a richly ornamented cope, under an elegant canopy, engraved on brass," &c. &c. See Lyfons's *Cambridgeshire*, p. 64. Part of the canopy and finale have been omitted on account of the smaller dimensions of our plate. The pattern of the embroidery, as may be seen, is far from being inelegant, and the recurring initials, (W. F.) roses, and other ornaments, are engraved with no inconsiderable care and neatness.

Philosophers have remarked how frequently man has stumbled or stooped short at the very threshold of improvement. From the time of the Crusades, Great Britain has been in possession of an art of engraving from which ink might have been delivered, and consequently impressions multiplied, either on the same vellum on which books were formerly written, or, since the middle of the 12th century, on paper itself: yet until about the year 1460, no man appears to have thought of delivering ink from the incisions of the graver.

Whether accident or design, and whether Italy or Germany had the honour of giving birth to an invention, of which three centuries and a half have not served fully to develop the important consequences to society, has been much disputed among the curious. Mr. Strutt is among the number of those who have pursued these inquiries with considerable diligence. After discussing the German and Italian pretensions, he at length brings forward an impression from an engraved brass plate in his own possession, which he conceives to be English, and which he thinks *may* claim the palm of early date. Its style of art is truly that of the early German school, and also that of the engravers of the English sepulchral brasses of the fifteenth century; yet from another circumstance, which shall be mentioned anon, the writer of this article is led to think that Mr. Strutt's

## ENGRAVING.

Strutt's plate, and the tenor of his reasoning thereupon, are more curious, than his conclusion is well founded.

Mr. Strutt says, "no one seems to have supposed that we could lay even the most distant claim to a rivalry (much less to a priority) with respect to the early practice of engraving, with any of the continental nations famous for the arts. But when we consider how many engravers we had in England, about the time in which the discovery of taking impressions from copper-plates was made, as the many monumental engravings remaining in our churches to this day sufficiently testify, (and a little examination of these early specimens of the art will prove how well they were adapted to the purpose of printing,) we shall readily conceive that if they did not themselves discover this mode of multiplying their works, they would at least have instantly adopted it, as soon as the knowledge of such an invention had reached them."

There can be little doubt of the antiquity of the engraving here produced; and that it was made for the purpose of printing, the letters being reversed upon the plate sufficiently prove. So that if it should be urged, though we see no kind of reason for such a supposition, (this is surely more than strict criticism will concede to Mr. Strutt,) that the plate itself was executed abroad, at the command of some English devotee, it must at least be granted that the mode of taking impressions from it was understood in England, or the plate could not have been of any use to the owner of it; and that the engraving was the work of some English artist, or executed at the design of some English personage; no one, I conceive, will doubt on examining the contents of the inscriptions. They consist of particular invocations to saints, comprehended in seven compartments, the initial letters of each invocation or prayer being ornamented with the representation of the personages to whom it is addressed." Here follows a particular description of the several compartments.

"The address to the English saints in the fifth petition, plainly, we think, determines the country to which it belonged. The style of the drawing, and the manner in which the little figures are composed, being placed in the initial letters, bear an exact resemblance to the illuminated delineations which we meet with in manuscripts of the fifteenth century, especially towards the commencement of it; and the writing also has every appearance of equal antiquity."

If we should proceed thus far with Mr. Strutt, and admit his reasoning, it will scarcely be practicable to travel with him further, though he be in general, as to matters of fact, an excellent guide. The invocations, which cover the far greater part of the plate, are not in the English, but the Latin language, and Mr. Strutt informs his readers, that they are "evidently stamped upon the plate with small punches, and re-touched afterwards with the graver." Now, no man would cut an alphabet of punches, (or punchcons, as they are sometimes technically termed,) for the sake of engraving, or stamping, such a plate as Mr. Strutt has brought forward, nor would probably any cause of less magnitude than the formation of matrices for an alphabet of moveable types, induce an artificer to bestow the time and pains, necessary to the production of such an alphabet of punchcons. From this single circumstance, the present writer is inclined to refer the engraving in question, in whatever country it may have been executed, to a period subsequent to the invention of moveable types; consequently if it was executed in England, it must have been after the year 1471, when, according to Dr. Middleton,

Caxton had returned from abroad, and began to print books in Westminster Abbey.

Another reason, which does not seem to have presented itself to Mr. Strutt, why the invention of printing with the rolling press from plates of metal cannot, in fairness, be assigned to England, is that to suppose this art to have been known here before the experiments of Finiguerra, we must also suppose that almost a century elapsed between the first and second examples of English copper-plate printing, which is a thing not to be supposed for a moment.

Of the engravings that accompanied an edition of Vesalius's anatomy, which was printed in England in the year 1545, Mr. Ames says, "these plates are some of the first rolling press printing in England." Of these plates, Thomas Geminus, or Gemini, was the engraver: they were not the very first that were published here. "The birth of Mankind, otherwise called the Woman's book," made its appearance in 1540, and contains some small anonymous copper-plate cuts, yet Geminus might possibly have begun his engravings more than four years before the date of their publication: at least he is the first engraver in England of whose name we are in possession, and whose works were printed on paper.

The first edition of Geminus's Vesalius was dedicated to king Henry VIII. He published a translation by Nicholas Udal, of the same work, in 1552, and dedicated it to Edward VI. The translator in his preface says, "Accepte therefore jentell reader, this treatise of anatomie, thankfully interpreting the labours of Thomas Gemini, the workman. He that with his great charge, watch and travayle, hath set out these figures in pourtrature, will most willingly be amended, or better perfected of his own workmanship, if admonished."

Those who have seen the masterly wood engravings to the original Vesalius, published at Padua, in 1542, engravings that were done under the eye, and, as some have said, touched by the hand, of Titian, will perceive that Gemini has left abundant room for admonition: yet the consideration that his work was a first attempt, at once to transplant a new art to England, and to extend the knowledge of anatomy, will probably be received as no unsatisfactory apology for the defects of these engravings.

Gemini lived in Black-Friars: he printed and published other books, among which are a small tract on midwifery, with copper-plate engravings, (which is, perhaps, the same that is mentioned above, under the title of "the Birth of Mankind, &c.") a prognostication relating to the weather, the phenomena of the heavens, &c. decorated with a number of cuts, and another edition of his Vesalius, printed in 1559, and dedicated to queen Elizabeth.

Lord Orford has observed that, "so congenial an art as engraving, when once discovered, could not fail to spread in an age of literature. That accomplished prelate, archbishop Parker, who thought that whatever tended to enlighten and cultivate the human mind, was within his province, seems to have been the most conspicuous patron of the art, in the reign of Elizabeth. He employed, in his palace at Lambeth, a painter and two or three engravers. Of these engravers, the chief was Remigius Hogenbergh, who twice engraved the archbishop's head, which, if Vertue be right, was the first portrait printed in England, from an engraving on copper; Remigius had a brother whose name was Francis, by whose hand is extant a print of queen Mary I. dated in the year 1555. Under it is written "Veritas Temporis Fida." In the set of Saxton's maps, those of Gaul and Belgium are by this artist,

## ENGRAVING.

and he has also engraved *views* both in Bruin's *Civitates Orbis Terrarum*, printed in 1572 at Cologne, and in Abraham Ortelius's *Theatrum Orbis Terrarum*, printed in 1570 at Antwerp. On the foreground of one of the views contained in the latter work, are two figures dressed in the costume of the times, one of which is the portrait of Ortelius himself, (as the inscription beneath informs us); and the other that of Hoefnagle the engraver, who, though a native of Antwerp, was among the first of those who practised the art in England. The map of England in this work was by Humphrey Lhuud of Denbighshire, and that of Spain by Thomas Geminus, whom we have already mentioned. Lord Orford thinks it creditable to England, that we had at this time, "professors worthy of being employed to adorn Flemish editions; Flanders being at that time a capital theatre of arts and learning;" and Ortelius himself commends the English engravers, specifying besides those whom we named, Antony Jenkenfon, and Robert Leeth.

Christopher Saxton deserves mention here, for at once extending the knowledge of our national geography, enlarging the field of engraving, and raising himself to eminence from the condition of a servant. He was a native of Yorkshire, and lived at Tingley, near Leeds, in the service of Thomas Sekeford, esq. master of the Requests, and of the court of Wards. Encouraged by this gentleman, who kindly assisted him with money, Saxton undertook to make a complete set of maps of the counties of England and Wales. Many of the plates he engraved himself, and in others was assisted by Francis Hogenbergh, Nicholas Reynold, and Augustin Ryther. Six years were employed in the work, which commenced in the year 1573. These were *the first* county maps that ever appeared in England, and Thoresby says of that of Yorkshire, which is three feet wide, that it is "the best that ever was made of that county." Ryther had the chief hand in engraving it, and at the corners are views of the city of York, and the port of Hull. These maps are also adorned with the royal arms, and those of the patron "Master Sekeford," and are dedicated to the queen.

In lord Orford's catalogue is a worthless portrait of George Hoefnagle, who engraved about this time a map of Bristol, and a view of the palace of Nonfuch, which, though once so magnificent, is now only known from description and the print of Hoefnagle. He worked entirely with the graver, and, as has already been mentioned, was one of those employed by Ortelius, in his great work, which may truly be called so, when we consider the time when, and the circumstances under which, it was produced.

We have passed over Cole, Bettes, de Brees, and others: and even the names of many of those who served to mark no era in the art of which we are here tracing the progress in England; who neither invented nor introduced a new style, nor distinguished themselves in those which were previously known and practised; we shall pass over them with a general reference to Strutt, Grainger, and lord Orford's catalogue, where their names and the dates of their works may be found, with such lists of their performances as those authors, with the assistance of George Vertue, were able to form or collect.

Notwithstanding the praise of Ortelius, English copperplate engraving retained, for more than an hundred years, much of its original coarseness and vulgarity. The style of Reginald Elstracke, who lived at the close of the sixteenth and beginning of the seventeenth centuries, is occasionally somewhat neater than that of his predecessors, but still desti-

tute of taste. His instrument was the graver, but faint indeed are the mental rays that attended its progress.

Elstracke worked chiefly for the booksellers; and his best works are portraits, which are for the most part, if not entirely, after his own drawings. They are in number at least thirty; and among the best of them are those of sir Philip Sydney, engraved soon after his death, and "BAZILIOLOGIA, or the true and lively Effigies of all our English Kings from the Conquest to the present time" (1618.) His portrait of queen Mary of Scotland is probably, on the whole, his best performance.

Francis Delaram was contemporary with Elstracke. His workmanship, for it can scarcely yet be called art, and certainly not fine art, was somewhat neater than that of Elstracke, but equally tasteless. The squareness or rectangularity of his crossings gives a peculiar dryness to his style of engraving; he drew but indifferently, his outlines are hard, and his draperies heavy. Unless we may except the following plates, which are after his own designs, his portraits are the best of his works. The frontispiece for "Wyther's Preparation to the Psalter," ornamented with emblematical figures, and dated 1619. The frontispiece to "The Seven golden Candlesticks," 1624. "Nero Cæsar, or Monarchie Depraved," 1627; this also is a frontispiece. And the best of his portraits are those of "James the First," an upright whole sheet print, as large as life. "Queen Mary and Queen Elizabeth," small uprights. "Henry Percy, Earl of Northumberland," dated 1619. "Frances, Duchess of Richmond and Lenox," and "Sir Thomas Gresham."

But the family of the Passes, or *de Passes*, of whom the elder came hither from Utrecht, early in the seventeenth century, introduced a better taste, and a neater and more elaborate style of engraving than had hitherto been practised in England.

Crispin de Passe was a man of letters, studious, and of a liberal mind. Holland's *Heroologia* was embellished and published at his expence; and in the preface to a drawing-book, published by him at Amsterdam, in the year 1643, (after his departure from England,) he discovers some knowledge in geometry and perspective; gives directions for the proportions of the human body; for drawing in the academy by lamp light, and for the use of the lay-figure in studying draperies; and details the proportions of horses, lions, and other quadrupeds, and of birds and fishes. In the same preface he says of himself that he applied early to the study of the arts, and mentions Rubens, Bloemart, and other distinguished contemporary artists, as his friends and encouragers: but he appears also to have looked with advantage at the neater productions of the German school of engraving. The following is a tolerably just estimate of his powers as an artist, and is from the pen of the late Mr. Serutt.

"Passe worked entirely with the graver, in a neat, clear style, which has much originality; and, excepting some little stiffness which frequently appears, and the want of harmony with respect to the distribution of the light and shadow, (a fault which prevailed at the time in which he lived,) his best works possess a very considerable share of merit, especially his portraits, many of which he drew from the life; and the far greater part of his historical and emblematical subjects are engraved from his own compositions. He drew the human figure very correctly," (but the proportions and style of his figures are those of the school of Rubens,) "and marked the extremities with a degree of exactness, not usually found in the works of those masters who employed themselves upon small subjects."

## ENGRAVING.

Mr. Strutt should have recollected here, that exquisite examples of delicate marking and elaborate workmanship might then have been seen, and, probably, were seen by Crispin Passe, in the works of the Behams, Penz, and those other German artists who are emphatically termed the *little* masters; particularly in the engravings of Bartholomew Beham, who had studied under Marc Antonio.

The sons of this artist, who were Crispin junior, William, and Simon, and his daughter Magdalen de Passe, followed the instructions and the style, and in some instances surpassed the merits, of their father; though the works of Magdalen, the first female engraver we read of who practised the art in England, are not equal to the best of those of her brethren. In three plates from Ovid's *Metamorphoses*, which she has engraved after pictures by Elsheimer, she has judiciously imitated the style of count Goudt, but has not produced the same forcible effect, nor attained the same exquisite degree of finish. Lists of the numerous portraits and other engravings by this family, may be seen in lord Orford's Catalogue, and Mr. Strutt's Dictionary of Engravers; and in the Royal library at Paris, before the revolution, was a collection of their works in large volumes, of which there were either two or three.

From Simon Passe the art descended to his pupil John Payne. Other engravers were practising in England at the time, but of inferior merit. Payne had caught the mantle of the Passés. Strutt says of him that "he was a man of genius, and though his works are not very numerous, they nevertheless manifest his superior abilities. He was recommended to Charles I., and had a fair prospect of making his fortune; but careless of that as he was of his fame, he neglected his business and died in indigence, A.D. 1647 or 48, before he had reached his 40th year. His chief engravings consist of frontispieces and other book-plates, and portraits. But he also engraved a variety of other subjects, such as landscapes, flowers, &c. His portraits, however, are, in my opinion, by far his best works. Those he executed entirely with the graver in a free open style, so managed as to produce a very pleasing effect. Mr. Evelyn, speaking of this artist, commends him also for a ship which he engraved. This ship, as Vertue informs us, was the Royal Sovereign, built by Phineas Pett. The print was of a prodigious size, and engraved on two plates, being, when joined, three feet long, by two feet two inches high." His best portraits are from Cornelius Janfen.

Having proceeded thus far with the progress in England of the art of engraving on *copper*, it behoves us to attend to the introduction and early progress of that of engraving on *wood*.

The art of engraving, and printing from, blocks of wood, was introduced into England about the same time with the mode of printing with the rolling press from engravings on copper: if, indeed, *wood* were really the material used for those engravings which are called, and generally supposed to be, wood engravings, and which are common from the time of the first promulgation of the art through the sixteenth and the two following centuries, and where the printing ink is evidently delivered from "lines crossing each other," and with the letter-press.

The earliest English engravings of this kind which the present writer has examined, unless those which are published with the mark of Holbein are really by his hand, and were any of them performed after his arrival in this country, are those of Christopher Switzer, who lived at the close of the sixteenth and beginning of the seventeenth centuries. He was probably a German by birth, though here bred in England. Vertue says, he cut a set of the broad seals of England, which

may be seen in the Harleian library, but impressions from the blocks of coins and seals which he cut for Speed's history are not uncommon; and here the remarkable dark crossings occur, and may be particularly observed in the four blocks which are entitled "portraits of the ancient and of the more civil Britons." Speed calls this artist "the most exquisite and curious hand of that age," and he probably was so, if we confine the remark to wood-engraving, and to England. Evelyn says of Switzer's son, who succeeded him in his profession, and was also named Christopher, "we have likewise a Switzer for cutting in wood, the son of a father, who discovered his dexterity in the herbals set forth by Mr. Parkinson, Lobel, and divers other works with due commendation;" which shews that the elder Switzer engraved the blocks of botanical subjects for Lobel's observations, and Parkinson's "Paradisus Terrestris," which was published in 1629.

It may have been perceived that of the fact of dark lines crossing each other, being printed from the surfaces of engraved blocks and with the letter-press, the present writer entertains considerable doubt. His doubt is founded on the extreme difficulty, amounting to impracticability, though not to absolute impossibility, of cutting away the minute lozenges of wood, or interstices between the crossed lines, so as to leave such a surface of dark crossings as must have presented itself to the letter press printers of this period.

To print dark crossings from the incisions of the graver, and with the rolling-press, may be conceived to be comparatively easy: but as printing from the *surface*, and with the letter press, was preferred on account of its superior facility, we are reduced in reasoning upon these engravings, if we suppose them to have been performed on *wood*, to the monstrous absurdity of supposing, that a difficult and tedious, was preferred to a simple and easy process, and that on account of its superior facility!

These considerations have led to the supposition that the prints in question were not taken immediately from the engravings, but from casts of some kind, for which the engravings; on whatever substances they were performed, did but serve as matrices or moulds. Yet wood cannot be cast in moulds: and in the library of Mr. Anthony Carlisle, professor of anatomy to the Royal Academy (whose name is, undesignedly on the part of the author, omitted in a note to the volume of lectures on engraving delivered at the Royal Institution, p. 205.) are two books illustrated with letter press engravings, which appear to contradict the above hypothesis. It may not be impertinent here to transcribe a passage from the *manuscript* of the lecturer.

"I have to regret that this part of the lecture is so little better than a statement of doubts. Since this volume has been in the press, I have seen, in the library of Mr. Carlisle the anatomist, a copy of Johnson's translation of Ambrose Parey's anatomy, printed in 1691, which is illustrated with letter press engravings where dark crossings frequently occur, and in the preface to which the author says, 'the figures in this work are not the same used by my author; but according to those of Bauline, which were used in the work of Dr. Crook.' Upon referring to the latter work, which I found in the same library, and which was printed in 1631, it was evident that the prints were not copies, but impressed from the very same engravings: but there was this remarkable difference which *ordinary* incredulity could scarcely stand against, that in Johnson's work the prints were obviously impressed from some substance which had been *worm-eaten* in the course of the sixty years it had lain by, and which could not therefore have been *metal*." The remainder of this note would be superfluous: the inference is obvious.

## ENGRAVING.

obvious. But, the public must not be led astray, nor must the author of that note let pass this opportunity of controverting himself.

It has since come to his knowledge, and is an undoubted fact, that old lead is not unfrequently found perforated by worms, or by some small animalculæ, which leave behind circular holes of exactly the same kind and size, which we so frequently see in old wooden furniture, books, &c. He resumes therefore his opinion, and indeed a further and more particular inspection of the productions of this kind, of the German school, has confirmed his belief, that the numerous prints produced at this early period in Germany and the Low Countries, which are supposed to be impressed from engravings on wood, are really printed from metal casts.

As Dr. Crook's anatomical work was published but two years after Parkinson's *Paradisus Terrestris*, it is probable that one of the Switzers engraved the anonymous anatomical figures which are the subjects of the above comments. The art of engraving, on whatever substance was then employed to enable the printer to produce dark crossings from the surface of the work, was an exotic transplanted from Germany or the Low Countries, and appears never to have taken root in our soil. It died away with or soon after the Switzers, and has never revived since: for the art of engraving on wood, as practised by the Bewicks of Newcastle and their disciples, and imitators, is to be considered as quite a distinct art. But, for further information on this subject, see **LETTER PRESS ENGRAVING**, and **WOOD ENGRAVING**.

Contemporary with the younger Switzer and with Hollar, of whom we shall presently treat, were Robert VanderVoerft and Lucas Vorsterman, who were rival competitors for public fame, and rivals also in the favour of king Charles I. Charles was the first English monarch who was sufficiently sensible of the beauty of engraving, and of the popular and important purposes to which it might be applied, to appoint an engraver royal. The king took care to see that the title was not worthlessly thrown away, in mere kindness to a courtier, and Voerft was the first artist on whom that honour was conferred. He was a native of Holland, and in what year he came hither is uncertain. He was an able draftsman, and hatched his drawings with pen and ink, as was the general custom of the artists, particularly the engravers, of that period. A drawing of this kind performed on vellum, and of which the subject was the Madonna with the infant Jesus and St. John, he had the honour of presenting to the king, for whom he afterwards engraved a portrait of his majesty's sister, and a plate from a picture which Vandyke painted to supply the place of that one of Titian's Cæsars which by some accident had been lost or destroyed: so that Voerft's title was not merely nominal. He engraved also from Vandyke, the portraits of Charles I. and his queen; (from the same celebrated picture which has been subsequently engraved by Vertue) that of the queen alone; sir Kenelm Digby, Inigo Jones, and several others, of which a list may be seen in lord Orford's catalogue. He handled his graver in a bold, free, and commanding style.

The style of Vorsterman exhibits more careful finishing and painter-like feeling, and must on the whole be allowed to be superior to that of his rival. He was to Rubens and Vandyke in England, and the Low Countries, what Marc Antonio was to Raphael in Italy. He may be said at once to have successfully translated and stereotyped the great originals of those very distinguished painters.

Mr. Strutt says of him with great truth that no one ever engraved more successfully from the pictures of Rubens: than whom, no painter that ever lived had the pleasure of seeing so great a number of his pictures finely engraved.

Vorsterman drew the human figure with correctness and taste. He was master of the graver, and could handle it with the utmost facility; but he paid much greater attention to the general effect of his prints, than to the regularity of the strokes; and like Gerard Audran, wished to enter into the thoughts of the master, and transcribe on copper the very life and spirit of his pictures, rather than shew his own dexterity in the mere mechanical part of the workmanship. The heads of his figures are finely drawn, and the extremities marked in a very masterly manner. Vertue mentions with approbation two drawings by Vorsterman, namely, a portrait of prince Henry, and a woman's head, after Leonardo da Vinci.

This celebrated engraver was a native of Antwerp, but from whom, or whether from any master, he learned the principles of painting and engraving, does not appear. He came over into England about the year 1623, and was occasionally employed both by king Charles I. and the earl of Arundel. His engravings are numerous, and chiefly from Rubens, Vandyke, and Holbein. Among those which may be mentioned with distinction are; from the former master, "The fall of the Damned," (a large upright); "The battle of the Amazons," a large and grand plate, printed on six sheets; "Lot leaving Sodom;" "The temptation of Job;" "Susanna and the Elders," and several others, particularly the "Return from Egypt," which he has treated in a manner differing from his usual style, and more bold and open. From Vandyke he has engraved a dead Christ, supported on the lap of the Virgin, and a considerable number of admirable portraits, among which are those of Charles I. and Vandyke himself; and from Holbein, he has engraved "Thomas duke of Norfolk," with the staves of lord treasurer, and earl Marshal, "Erasmus, sir Thomas More," and the painter himself. Sir Thomas has here a flatter face and smaller bonnet than in other pictures of him; and from the circumstance of Holbein's pencil being placed in his left hand, may be inferred, not that this print was a copy from another without being reversed on the copper (as lord Orford has surmised) but that Holbein painted with his left hand: a truth which the painter here meant to say of himself, and which the engraver has faithfully reported.

Nor must the illustrious name of sir Anthony Vandyke be omitted, in enumerating those of the artists who contributed to accelerate the progress of British engraving. The portraits which he etched of Snyders, Vorsterman, Paul Pontius, and other distinguished artists who were his contemporaries and friends, excited the just surprise and emulation of the painters and engravers of that age, and the best of them have continued to the present to be examples of excellence. Among the best may be reckoned that head of himself, looking over his shoulder, where he has introduced the golden chain which he had the honour of receiving, together with his majesty's picture in miniature, at the hands of Charles I. a circumstance which serves to shew that he etched this plate at least, and presumptively others, after his arrival in England. In some of those which he had previously executed, we see him contending, as it were, against the difficulties of his own imperfect knowledge of the newly acquired art, and that his plates are accordingly blurred with accidental scratches, and blotted and stained with foul biting, which all the skill of Bolswert, Neefs, and Vorsterman, who severally employed the graver in finishing most of his draperies and some of his faces, has not been sufficient to obliterate or conceal. His style of etching is original, vigorous, free, and expressive, and in some instances he has finished his heads with considerable care. The transcendental

## ENGRAVING.

taste and judgment which he has so amply displayed in his pictures, guided and determined his hand in etching, and though nearly two centuries, which have boasted of their refinements, have elapsed since the period of their production, his "Ecce Homo" and his portraits, still preserve their stations in the collections of the tasteful, and are still esteemed among the most highly valued studies both of the portrait painter and engraver. By liberating British portrait engraving from the stiff regularity of the graving tool, which had before been too much regarded as a test of merit, Vandyke extended the views of the tasteful, while he taught the true value of outline, and light and shade.

It would not now be easy to ascertain the precise time when that important branch of engraving, which is technically termed *etching*, (for an explanation of its process, see the article *ETCHING*,) was introduced into England. Ortelius's and Bruin's publications contain some prints where etching appears to be mingled with the work of the graver, but if they are by English artists, those artists probably acquired their knowledge of etching in Flanders, where they practised it; and on the whole it seems highly probable, that no etching was performed in England till the period of Vandyke's and Hollar's residence in London, and that the honour of having introduced it belongs to one or the other of these distinguished characters. Vandyke was here and in high favour at the court of Charles I. when Hollar arrived, but whether he had then performed any of his admirable etchings is no where recorded; and as they are without dates, cannot now be easily ascertained. As neither of these distinguished men was the discoverer of an art, though each was the inventor of a style, it may be enough to believe it highly probable, that Vandyke was the first person who etched portraits in England, and Hollar the first who etched landscape and natural history.

It is not certain, that William James Delft, or *Van Delft*, (for he was so named from the place of his nativity,) was ever in England. Yet from his styling himself the king of England's engraver, and engraving portraits of Charles I., his queen Henriette Maria, and the duke of Buckingham, it should seem to be not improbable that he succeeded Voerft. Strutt says of him, that "he drew and painted portraits with great taste, and in a style that acquired him considerable reputation; but as an engraver of portraits he is more generally known, and in that light only I shall consider him. He worked entirely with the graver, and handled that instrument with the greatest facility. He drew correctly, and his best prints are very finely finished. Considering the great number of plates which were completed by the graver of this artist, it is not reasonable to suppose they should be all alike or equal in merit. Accordingly I shall distinguish two manners in which he engraved, and produced many excellent plates in both: first, a bold, powerful open style, productive of a fine effect; and as a specimen of it I would refer the reader to the portrait of Hugo Grotius, dated 1652: secondly, a neat and much more finished manner, as we find in the admirable portrait of Michael Miravelt (a near relation to the engraver,) from a picture of Vandyke." From the pictures of Michael and John Miravelt, he engraved a considerable number of portraits.

Wenceslaus Hollar, who has been already named, if not the first person who practised the art of etching in England, was the first who particularly distinguished himself in etching landscape, shipping, antiquities, and natural history.

This distinguished artist, a gentleman by birth, was a native of Prague in Bohemia, and intended by his parents to have been educated to the study of the law; but the civil commotions which happened in his youth, and which

led to the memorable battle of Prague, obliging them to abandon this intention, and his genius for art discovering itself about the same time, he was placed under Marian, an able designer and engraver of views, and by the time he had attained the age of nineteen, Hollar produced two plates, of which the subjects were an *Ecce Homo* and a *Madonna*, and child, (the latter from Albert Durer,) which drew forth the notice of the public, and confirmed the hopes of his friends. In the course of the next year (1636,) he engraved another of Albert Durer's *Madonnas*, and a plate which the superstitious might regard as ominous of his future fate, of "Fortune surmounting a Globe," which was also from Albert Durer.

He soon afterwards excelled in drawing geometrical and perspective views and plans of buildings; ancient and modern churches and abbeys, cities and towns; landscapes; and various kinds of natural and artificial curiosities, some of which he executed with a pen in a very masterly and peculiar style. To this art of drawing with a pen, he subsequently added the use of water-colours, which he occasionally, in the treatment of such subjects, as butterflies, beetles, &c. heightened and enriched with gilding in a very beautiful manner, as the volume of his drawings now in the possession of John Townley, esq. F. R. S. and F. A. S. of Park street, Westminster, abundantly testifies.

After passing some years in travelling through Germany, during which he drew and engraved views of Frankfort, Wurtzburg, Cologne, and other of its principal cities; but where he met with little encouragement: the earl of Arundel, then on an embassy to the Imperial court, met with him at Cologne, and being struck with his uncommon abilities, and particularly delighted with a large drawing of Prague, which Vertue says, "was curiously and exactly done with the pen and pencil," took him under his protection, and Hollar travelled in the ambassador's suite, from Cologne to Mentz, Prague, Nuremberg, Augsburg, Wurtzburg, Frankfort, Regensburg, Vienna, and finally to England, where it is said the noble earl recommended him to the favour of king Charles I.

There is some reason to fear that lord Arundel's patronage of Hollar was more nominal than real; and that the vanity of the patron was more gratified, than the fortune of the artist was promoted, by their connection. That Hollar was left destitute by the death of this nobleman, notwithstanding that political, were then added to his professional, merits, (for he was a zealous adherent to the cause of royalty and lord Arundel,) is freely excused on the ground of his lordship's own reverse of fortune, but it appears to imply more neglect than the liberal would else be disposed to impute to this nobleman, that during the first year of Hollar's arrival in England he was under the necessity of drawing and etching his view of Greenwich, which is more than two feet in length, for the paltry sum of thirty shillings! Yet the reader must wish in vain for a more honourable contrast between the parsimony of Stent, who purchased a *commodity* of Greenwich, with no other view than to enrich himself by the profits it might produce; and the liberality of the exalted peer, who deserved his exaltation as the patron and protector of talent, alive to the charms of art, and kindling with the flame of contemporary genius.

But it must be candidly allowed that the art of Hollar had little affinity with that of Vandyke, and, so dependent is the judgment in fine art of some men, upon the opinions of others, that the merit which lord Arundel thought he had discovered at Cologne or at Prague, might have faded in his own estimation when he approached the light of the court of London. Notwithstanding his own partiality and native

## ENGRAVING.

native feeling for the merits of Hollar, Vertue is obliged to confess of him that "it is certain he could not so well enter into that master's (Vandyke's) true manner of drawing in his grace and touches, as other engravers, some in England and others abroad, who had studied his way or manner of drawing and painting; for which reason "he could not obtain Vandyke's recommendation, nor that of his admirers." Portrait painting was then the reigning fashion in England, and as the national taste for art was basking in the meridian splendour of the powers of Vandyke, it is not surprising that the less fortunate and more humble claims of Hollar were little seen, and met with small comparative encouragement.

Though the warmth of lord Arundel's patronage might perhaps be damped by these causes, he continued in some degree to befriend our artist. On his arrival in London, Hollar sat down with his habitual industry to engraving, and after producing his large plate of Greenwich, which shewed what he could do in this department of engraving, put aside for a time his talents for landscape and natural history, in order to accommodate himself to the public occasions and the prevailing taste, and soon completed an equestrian portrait of his patron, with two plates of king Richard II. kneeling before his patron saints, from an ancient altar folding table, and some other works from the Arundelian collection, including the curious cup which was designed by Andrea Mantegna.

In the year 1641, which was the year of Vandyke's decease, he engraved some portraits, including those of the king and queen, from the pictures of that celebrated painter. He had now been introduced to teach drawing to some branch of the royal family. Vertue thinks it was to teach prince Charles, having "seen a book mounting the arms or badge of the prince of Wales, (the crown and feathers,) wherein were drawings of parts of faces, &c. to begin to learn from, with some of Hollar's hand-writing;" but in an inscription under his portrait, published at Antwerp in 1648, and which inscription is supposed to have been supplied by himself, he says, he "had been domestic servant to the duke of York."

However this may have been, the civil wars which broke out soon after this mastership or servitude, tossed Hollar about with the royal party, ruined his better hopes, and obliged lord Arundel to return into Flanders. The engraver being left behind, resolved to try the fortune of war, and entering the army under the command of the marquis of Winchester, was made prisoner at Basing-house, in Hampshire, from which having, with some difficulty, effected his escape, he went over to Antwerp, in the year 1645, and once more sought the patronage or consolation of the earl of Arundel. He remained in that city for some years, endeavouring, through means of his art, to retrieve his shattered circumstances; but his patron going to Italy for the benefit of his health, and dying at Padua in 1646, Hollar was left to the accidents of precarious encouragement and the avarice of trade. He fell again into distress, and was obliged to work for the book and print-sellers at very low prices.

Under such circumstances were produced his book of heads, after da Vinci; his thirty-eight plates of shells, with many other subjects from the Arundelian collection; a considerable number of landscapes after Breughel, Elsheimer, Teniers, and other masters, and a still greater number of portraits, among which were those of Charles I., Charles II. when a youth, after Vandyke, the duke of York, after Teniers, which is now become very scarce, and his own portrait, after Meyfens. At the period of the restoration Hollar re-

turned to England, where, though he found sufficient employment to occupy his time, the prices he received for his engravings were so very inadequate to the labour which they necessarily required, that he could but barely subsist; and the plague putting for some time an effectual stop to business, and being soon after succeeded by the fire of London, the pecuniary embarrassments of our artist were greater than ever, of which Leake, Jennings, Mark, and those other dealers, for whom, in the course of the years 1666 and 67, he engraved various views and plans of London, before and after the great fire, did not fail to take advantage.

"Born to misfortune as the sparks fly upwards," it was soon the fate of Hollar to turn his hopes once more toward the court, for that protection and encouragement which commerce blindly refused him; and in the years 1668 and 69 he was employed by government under the orders of lord Howard, to make drawings of the town and forts of Tangiers, which he afterwards engraved. In this perilous service, he narrowly escaped being killed or made prisoner by the Turks. The ship, on board which he had embarked for England, the *Mary Rose*, Capt. Kempthorn, fought seven Algerine Corsairs off Cadiz, and had eleven men killed and seventeen wounded; but Hollar escaped unhurt, and had afterwards the honour of engraving a plate of the battle.

On his return to England, he received no more for the difficulties and dangers which he had encountered, the drawings he had made, and the year he had spent in this arduous service, than one hundred pounds; and this, according to Vertue, was not obtained till after long attendance at the public offices, and experiencing many of those rebuffs "which patient merit from the unworthy takes."

From this time till the year 1677, when death put a final period to his exertions, he spent much of his time in travelling through the northern counties of England, and delineating and engraving their topography, and produced those plates which are now objects of so great curiosity, and will be yet more highly valued by posterity, as shewing what England was (and what Hollar was) during the reign of Charles II. The plates for Thoroton's Nottinghamshire and Sandford's Genealogical History, were engraved in the course of the three last years of his life.

He used to work for the mercenary book and print-sellers at the rate of fourpence an hour, always having an hour-glass before him; and was so scrupulously exact, that when obliged to attend the calls of nature, or whilst talking, (though with the persons for whom he was working, and about their own business,) he constantly laid the glass on its side, to prevent the sand from running. Yet notwithstanding his exemplary industry, and this rigid adherence to principle; notwithstanding his extraordinary merit as an artist; notwithstanding his loyalty and the past favour of lord Arundel and Charles I., Hollar died poor and miserable, after a life of vicissitude, and for the most part of suffering.

During the dissolute reign of the second Charles, who was to listen to the claims of modest and retired merit? The delighted purchasers of his "*Seleucus*," after Julio Romano; his "*Fountain of Pleasures*," or his "*Queen Sheba visiting Solomon*," (as will be the case under any reign where *patrons* are content to be acquainted with contemporary art only through the medium of parasites and dealers,) were either heedless of what befel their author, or were deceived into the belief that he was at least comfortably provided for; and while Stent, Overton, Green, and the rest of the dealers of that day, enjoyed their fire-sides in comfort, or rioted in the lap of luxury, on the profits of his works, the engraver of more than two thousand plates, which are since sought for through Europe, and most of which

## ENGRAVING.

which are after his own designs, expired in the very act of intreating the bailiffs, who had entered his wretched apartment, for a little forbearance.

Hollar's plates are for the most part etchings, touched here and there, where superior clearness was wanted, or the aquafortis had not accomplished its purpose, with the graver. His small plates are superior to his larger; his style of handling his etching-needle is pleasing, and was original; and, in the accuracy, freedom, lightness, spirit, and finish of his cities, abbeys, cathedrals, and some other of his landscapes, and his plates of natural history and still life, he much excelled his contemporaries; even those on the continent: but in drawing the human figure he was not equally well informed, and his hands and feet are therefore often defective.

In conformity with the false preference which fashion had conferred on works performed solely with the graving-tool, he attempted to execute some plates with the graver only, but has here failed of the success that attended him in etching.

Hollar appears to have been a meek-tempered man, and to have wanted the necessary confidence in his own powers or the public taste, to venture on publishing any of his own engravings; though Vertue ascribes this effect to a different cause, which, no doubt, was at least a concomitant, he says, "I don't find that at any time he worked for himself, to sell or publish, as has been customary with professors of that art (engraving) when they had substance of their own, or friends and interest sufficient." Alas! what is society if it befriend not the ingenious.

The innate love of engraving must be strong in some minds, or the necessity of practising that art must be imperious, for Hollar to have left successors. The truth, however, is, that in the department of his art, in which Hollar's merit chiefly resided, he had no successor, for Barlow, of whom we shall presently speak, was an English painter, who merely learned of him the process of laying etching-grounds and using aquafortis; and William Carter, Daniel King, and Thomas Dudley, who were all natives of England, and pupils of Hollar, rather followed him to the grave, than succeeded him in art. The former was used occasionally to assist his master; imitated feebly his style of etching; and is the engraver of the vignette head-pieces to Ogilby's Homer, and probably of many other of those anonymous book-plates that some collectors ascribe to Hollar. King is somewhat more conspicuous. He published "The Vale Royal of Cheshire" from his own drawings; and engraved for Dugdale's Monasticon, and some other plates of topographical subjects. Dudley has occasionally subscribed himself "quondam condiscipulus W. Hollar," and Mr. Strutt's account of him is as follows. "He was a native of England, and one of the pupils of the famous Hollar, whose manner of engraving he imitated. But though he never equalled his master in the lightness of his point or freedom of execution, his etchings are not without merit. His most considerable work was a set of cuts for the life of Æsop, prefixed to the last edition of his Fables, published by Barlow. He also etched the portrait of bishop Ruffel, which is subscribed Thomas Dudley Anglus fecit 1679."

R. Gaywood has also been mentioned as a disciple of Hollar, but he etched no views, or other landscapes, and in engraving portraits employed less of etching; and, in short, did not confine himself to the style of that master, but blended with it what he acquired from studying Vorst, Vorsterman, and the other engravers of the Vandyke school.

Gaywood engraved a considerable number of portraits, among which are those of queen Mary of Scotland, with a cross; the countess of Portland, Holbein, Vandyke, and Dr. Faustus. The only historical engraving of any conse-

quence from his hand is the couchant Venus of Titian, which was once in king Charles's collection, and since in that of the earl of Cholmondeley.

Of Francis Barlow much more may with the greatest truth be asserted. This artist was a native of Lincolnshire, but in what year he was born was not known. He received his first instructions in art from a portrait painter of final note of the name of Shepherd, and if he learned the use of the engraver's instruments from Hollar, he formed a style for himself.

The inventive powers of Barlow were extremely fertile. His great merit lay in designing and etching quadrupeds, birds, fishes, insects; in short, the whole volume of animated nature appears to have been open to his view, and in this respect, he is the fittest of all men to be the companion of that great moral philosopher Æsop, whose fables he has so admirably embellished. His human figures, which with considerable judgment, he occasionally introduced, exhibit the dresses and manners of his age; he had observed the natural instincts and customs of animals, and has delineated them with a fidelity which is surprising; and his landscape backgrounds often assume a grandeur which could only result from elevated ideas of art.

His compositions shew that he had studied the animal and landscape painters who preceded him, as well as nature herself, with advantage. In forming his style of etching, he has evidently looked at the animals of Hollar, yet is original, vigorous, free, and so happily varied, as to express the feathery and hairy surfaces of birds and quadrupeds with a degree of success which none of his predecessors, and only Hollar among his contemporaries, will bear to be compared with.

The frontispiece to his Æsop's fables, where Æsop himself appears surrounded by animals; the angler and entreating fish, with its landscape accompaniments; the prostrate camel; the battle of the frogs and mice; and the oak, and reed bending before the storm, may be mentioned with distinguished praise. His foxes, camels, asses, and wolves, are in general most excellent, and all his birds are so, without exception: but his lions, wherever they occur, are either ideal lions, and not well conceived, or shew that he had once seen and drawn from a bad model, and repeated it wherever he had occasion for a lion.

Part of "Monk's funeral" is Barlow's engraving: and several of the plates for Edward Benlowe's "Theophrastus," published in folio, A. D. 1652; and some of those for Ogilby's Virgil, are also designed and etched by Barlow.

That at some period of his life he had travelled northward, may be seen in the print which F. Place has engraved after his drawing of "the Bass Island," wherein he has introduced soland geese, curlews, gulls, and all the varieties of Northern sea fowl; and if he sailed thither from any port of Scotland, it was probably during this journey that he saw in the latter country an eagle soaring with a cat in its talons, of which he afterward engraved a spirited plate. This anecdote is recorded both by lord Orford and Mr. Strutt, who agree in stating that Barlow witnessed this contention in the air whilst he was drawing a view in Scotland, and that the cat's resistance had the effect of bringing both animals to the ground.

At one period of his life, probably towards its close, he resided near the sign of the Drum in Drury-lane. That he was industrious is attested in the great number of his productions; yet notwithstanding this circumstance, and the praise of superior excellence to which he is so justly entitled: and notwithstanding the assistance of (Mr. Strutt says) "a considerable sum of money," (he does not say how much) which was

## ENGRAVING.

left him by a friend, he died in indigent circumstances in the year 1702.

Francis Place has sometimes been spoken of as if he had learned etching of Hollar, but in a letter to Mr. Vertue he denies this; and indeed the style which he adopted and the number of plates which he has engraved after the drawings and pictures of Barlow, teaches us rather to think he must have studied under that master, if under any master at all. Lord Orford says "his prints are very scarce," but in a book which contains "sixty-seven excellent and useful prints of birds and beasts" after Barlow, to which modern students and even academicians are not a little indebted, and worn impressions of which book may now be purchased of Carington Bowles for half a guinea the set, are twenty plates of a moderate size, which bear the name of Place, beside others which on a critical inspection may be seen to be from the same hand. The birds in these prints are etched with so much of the spirit and feeling of Barlow himself, that they might well be suspected to be his own performance, but for the name of Francis Place, which is annexed; nor are his grassy foregrounds, and the foliage and ramifications of his trees less excellent.

"This ingenious artist was the son of Mr. Rowland Place, of Dinsdale, in the county of Durham." When young he was articled as clerk to an attorney in London, where he continued till the year 1665, when certain officers coming to shut up the house where he resided, on account of the plague, he took the opportunity of quitting a profession that did not accord with his inclination, "and of following (says lord Orford) the roving life he loved, and the arts for which he had talents."

In the course of his various rambles, he drew, painted, and engraved, as inclination prompted or opportunity occurred, besides discovering some occasional disposition to mineralogical research, and skill in the manufacture of pottery.

He drew and engraved views of Tintmouth castle and light house, the cathedral of York; Scarborough castle, several plates for Thoresby's Topography of Leeds, beside various other views in England, Wales, Scotland, and Ireland, and the figures for Godartius's book of insects.

His former biographers agree in affirming that during the reign of Charles II. he was offered a pension of 500*l.* per annum, to draw the royal navy, but declined accepting it, having a competence without, and from his natural love of independence and dislike of confinement. He died in the manor house of York in the year 1728.

Beside the etchings which are here enumerated, and several others, Place engraved the portraits of bishop Crewe, general Lambert, and Richard Thompson, in mezzotinto: to treat of the discovery and introduction of which art, we must return back a few years.

Mr. Evelyn has been justly ridiculed by lord Orford, for the mysterious and paradoxical manner in which he announces prince Rupert's discovery of mezzotinto. It is, perhaps, one of the most honest, most candid, and most happily expressed, of the numerous pages which his lordship has written on the subject of fine art. "Ancient sages, says he, used to wrap up their doctrines, discoveries or nonsense, in such unintelligible jargon: (as Mr. Evelyn's) and the baby world, who preferred being imposed upon to being taught, thought themselves extremely obliged for being told any secret which they could not comprehend. They would be reckoned mountebanks in this age, who should pretend to instruct without informing; and one cannot help wondering that so beneficent a nature as Mr. Evelyn's should juggle with mankind, when the inventor himself had consented that the new art should be made public.

"It is a trite observation that gunpowder was discovered by a monk, and printing by a soldier. It is an additional honour to the latter profession to have invented mezzotinto. Few royal names appear at the head of discoveries; nor is it surprising. One cannot expect that many of the least common rank should be blessed with uncommon abilities. Quickness to seize and sagacity to apply are requisite to fortuitous discoveries. Gunpowder, or printing, might have fallen in many a prince's way, and the world have been still happy or unhappy enough not to possess those arts. Born with the taste of an uncle whom his sword was not fortunate in defending, prince Rupert was fond of those sciences which soften and adorn a hero's private hours, and knew how to mix them with his minutes of amusement without dedicating his life to these pursuits; (like us, who, wanting capacity for momentous views, make serious study of what is only the transitory occupation of a genius.) Had the court of the first Charles been peaceful, how agreeably had the prince's congenial propensity flattered and confirmed the inclination of his uncle! How the muse of art would have repaid the patronage of the monarch, when for his first artist she would have presented him with his nephew! How different a figure did the same prince make in a reign of dissimilar complexion! The philosophic warrior, who could relax himself into the ornament of a refined court, was thought a savage mechanic, when courtiers were only voluptuous wits. Yet if the prince was defective in the transient varnish of a court, he at least was adorned by the arts with that polish which alone can make a court attract the attention of subsequent ages.

"Going out early one morning during his retirement at Brussels, he observed the sentinel at some distance from his post, very busy doing something to his piece. The prince asked the soldier what he was about? he replied, the dew had fallen in the night, had made his fusil rusty, and that he was scraping and cleaning it. The prince looking at it, was struck with something like a figure eaten into the barrel, with innumerable little holes closed together like friezed work on gold or silver, part of which the fellow had scraped away.

"The *genie second en experiences*, from so trifling an accident conceived mezzotinto. The prince concluded that some contrivance might be found to cover a brass plate with such a grained ground of fine pressed holes, which would undoubtedly give an impression all black; and that by scraping away proper parts, the smooth superficies would leave the rest of the paper white."

Communicating his idea to Wallerant Vaillant, a reputable painter then in the neighbourhood of Brussels, they made several experiments, and at last invented a steel roller with projecting points or teeth like a file, which effectually produced the black ground, and which being scraped away, or diminished at pleasure, left the gradations of light.

Such was the invention of mezzotinto according to lord Orford, Mr. Evelyn, and Mr. Vertue; but the baron Heinekin affirms that "it was not prince Rupert who invented the art of engraving in mezzotinto, as Vertue and several other authors pretend to say; but it was the lieutenant colonel de Siegen, an officer in the service of the landgrave of Hesse, who first engraved in this manner; and the print which he produced was a portrait of the princess Amelia Elizabeth of Hesse, engraved as early as the year 1643. Prince Rupert, he adds, learned the secret from this gentleman, and brought it into England when he came over the second time with Charles II."

The present writer has not seen the print thus spoken  
of

## ENGRAVING.

of by the baron: and the precise date of prince Rupert's discovery is no where mentioned. But if a mezzotinto engraving dated seventeen years before the restoration can be produced, and the date be genuine, it certainly goes far toward proving Heinnekin's assertion. Vertue acknowledges to have seen an oval head of Leopold William, archduke of Austria, in mezzotinto, that was dated in 1656, which he esteems the earliest. It is inscribed "Theodorus Casparus à Furstenburgh canonicus ad vivum pinxit et fecit;" but this argues little against prince Rupert's discovery, since it is quite within probability that Casparus might have learned the art from the prince or Vaillant during their residence in the Low Countries.

The earliest of Rupert's engravings in mezzotinto, that is now extant, is dated in 1658. It is an half length figure from Spagnoletto: the subject, an executioner holding a sword in one hand and in the other a head, which is probably intended for that of John the Baptist, and upon the sword are the initials R. P. F. surmounted with a coronet. It is further distinguished by the following inscription on a tablet beneath "SP in RVP. P. fecit. Francofurti. anno 1658 M. A. P. M."

Return we now to the historical progress of English engraving, properly so called; referring to the word *MEZZOTINTO*, for the improved modern process of that branch of the art.

Lord Orford speaks of William Faithorne the elder with distinguished praise, and has given a tolerably correct list of his engravings, which he has separated into five classes, and to which the reader, who may wish to arrange the works of Faithorne, is referred. He lived at the same period with Hollar, and about the year 1654 in the very same house; but the year of his birth has not been ascertained. He was the disciple of Peak, the painter and print-seller, who was afterwards knighted, for whom he worked three or four years. With Peak he espoused the royal cause, when the civil wars broke out between king Charles and his parliament; and with him, and probably with Hollar also, was taken prisoner at Basing-house; from whence he was sent to London, and confined for some time in the prison of Aldersgate. In this uncomfortable situation he exercised his skill as an engraver; and here he produced a small head of the first Villiers duke of Buckingham, which is in the circular style of Mellan.

At the solicitation of his friends, he was released from confinement, and permitted to retire to France: though Graham says, he was banished for refusing to take the oaths of allegiance to Cromwell, and that he studied several years under Champagne.

Vertue, who received his accounts of Faithorne from Mr. W. Hill Clark, and Mr. Bagford, lord Orford's librarian, seems to discredit these facts; but all agree that he found protection and encouragement in France from the abbe de Marolles, and obtained improvement under the justly celebrated Nanteuil.

The latter indeed is sufficiently obvious in his engravings. At his return to England, which lord Orford thinks was before the time of the protectorate, he married a sister of captain Croud, by whom he had two sons, and opened a print-shop opposite the Palsgrave-head tavern, without Temple-bar, assuming the sign of the Ship. Here he not only followed his art, but sold Italian, French, and Dutch prints, and also the engravings of other English artists; some of which are still to be seen with the subscription "sold by William Faithorne." And here he appears to have remained about 30 years.

"Some time after the year 1680," says lord Orford,

"Faithorne quitted his shop, and retired to a more private life in Printing-house yard, Blackfriars; still engraving, but chiefly painting from the life in crayons, in which art he had formerly received instructions at Paris from Nanteuil." He also painted miniatures, and drew portraits in black and white. Faithorne was a robust and vigorous man; but the misconduct and consequent misfortunes of his son William, broke down his frame and spirits, and he died in the year 1691, and was interred in the church of St. Anne, Blackfriars.

The principal part of his engravings appears to have been executed during his residence near Temple-bar, where he also wrote and published a "Treatise on Engraving," A.D. 1662, which he dedicated to his former master, sir Robert Peake. The contents of this book, as displayed in the title page, are as follows: "The Art of Graving and Etching, wherein is expressed the true way of graving on Copper; also, the Manner and Method of that famous Callot and Mr. Bos, in their several ways of Etching."

Portraits constitute by far the most numerous part of this artist's works. He worked almost entirely with the graver, in a free and clear style, paying more attention to the beauty of his lines than most of his British predecessors. In the early part of his life, he seems to have followed the Dutch and Flemish manner of engraving; but on his return from France, his improvement was evidently considerable. His portraits are his best works; and the best of his portraits are justly admired for their delicacy, freedom, and force of chiaro-scuro.

Mr. Strutt has distinguished the following among the more valuable of Faithorne's historical engravings: "a holy Family," from S. Vouet, a middling sized plate, in the style of Couvy; "a dead Christ," from Vandyke; "the last Supper," without any painter's name, in folio; "Christ praying in the Garden," the same; "the Marriage of Cana in Galilee," an etching, the same; "the Scourging of Christ," from Deepenbeck. Under this latter print is written "Faithorne Sculp. Antwerp, 1657," which date seems to have escaped the notice of Vertue, and to falsify the opinion that lord Orford, on his authority, had formed, that "Faithorne returned to England before the protectorate."

His portraits, as has been already intimated, are too numerous to be detailed in this place.

William Faithorne the younger was far inferior to his father as an artist. His principal works are portraits, scraped in mezzotinto, of which Vertue has particularized about thirty, with three prints of fancy subjects, and a head of St. Mary Magdalen.

John Fillian was also a disciple of the elder Faithorne, whose style and some of whose portraits he copied. He was living in 1656, but died at an early age. His principal works are, "a Head of his Master," looking over his shoulder, which is copied from a print by Faithorne himself; the portraits of "Thomas Cromwell," and "Paracelsus," and the "Frontispiece" to Heylyn's Cosmography, in folio.

Of Peter Lombart, Vertue has been able to trace little, but that he came from Paris, and returned thither after remaining for some years in England; to which Strutt adds, that he was a native of France, and came into England before the revolution.

He worked in a neat, laboured style, and discovers but little taste. His drawing is frequently incorrect; his outlines hard; his shadows deficient in force and boldness; his lights of too low a tone, and even his engravings after Vandyke are deficient in force, though he has discovered a

## ENGRAVING.

tolerable eye for the *harmony*, of *chiaro-scuro*. Yet he worked after the pictures of the greatest masters: after Raphael, Guido, Poussin, Annibal Carracci, and Vandyke. Among the best of his engravings are, "the last Supper," a large upright, from Nicholas Poussin; "the Angel appearing to Joseph," after Ph. Champagne; "the Crucifixion," from the same master; the "Frontispiece," and several other plates for Ogilby's Virgil. Among his portraits from Vandyke is that of "Charles I." on horseback, a large half-sheet print. From this plate he afterwards erased the face, and substituted that of "Cromwell;" and at a subsequent period, "with the vicar of Bray's graver," as lord Orford wittily says, restored the king's.

Vertue has enumerated twenty other of his portraits, which are chiefly after the same master; and to them may be added a set of twelve half-lengths of rather a large size, of which ten are portraits of celebrated ladies of the court of king Charles.

Notwithstanding his reserve in communicating prince Rupert's discovery of mezzotinto, John Evelyn, esq. of Wootton, in Surrey, is entitled to honourable mention in this place. He was the first English gentleman who wrote upon the subject of engraving; and though his "Sculptura" be deficient in artificial knowledge and feeling, it is a work of considerable erudition, and has contributed not a little to the advancement of the art; while it clearly evinces his love for engraving, the excellence of the example which he wished to set, and the general goodness of his heart. Lord Orford handfomely says of him: "If Mr. Evelyn had not been an artist himself, as I think I can prove [that he was], I should yet have found it difficult to deny myself the pleasure of allotting him a place among the arts he loved, promoted, patronized; and it will be but justice to inscribe his name with due panegyric in these records, as I have once or twice taken upon me to criticize him: but they are trifling blemishes, when compared with his amiable virtues and beneficence; and it may be remarked, that the worst I have said of him is, that he knew more than he always communicated."

The duration of the life of this great contributor to learning and the arts was protracted to 86 years, and he died in 1705.

It appears now to be agreed among the connoisseurs, that the five small prints of Mr. Evelyn's "Journey from Naples to Rome," which his biographer thought were etched by Mr. Hoare, are Evelyn's own performances; and to these Mr. Strutt has added a "Portrait of Dobson" the painter, from a picture by himself.

David Loggan was a native of Dantzick; he was born about the year 1635, and died in 1693. From Simon Pass, in Denmark, he is said to have received his earliest instructions in engraving; he afterwards resided in Holland, where he studied under Hondius; and a short time before the restoration he came to England.

His drawings of All-Soul's college being taken great notice of at Oxford, he was requested to undertake plates of the public buildings in that university. By these engravings he first distinguished himself; and at Oxford he remained a considerable time, and married Mrs. Jordan of a good family, near Witney. In the latter part of his life he resided in Leicester fields, London; where he died.

In satirising the vanity of a certain dramatic poet, Dryden says,

"And in the front of all his senseless plays,  
Makes David Loggan crown his head with bays."

Yet as Loggan's merits as an engraver were not such as to

crown his own with lasting reputation: his *name* will probably live much longer than his works will be cared for. He etched very little, and his style of engraving, though it has a certain degree of neatness, is stiff and tasteless. His portraits, of which he executed a considerable number, are chiefly after his own drawings in black lead, which he handled with more ability, at least with a better taste, than his graver.

Vertue has enumerated 76 portraits from the hand of Loggan, of which the principal are, three plates of "Charles II.;" "Mother Louisa of Louisa-hall," which it seems added much to his contemporary reputation; and "George duke of Albemarle," a half-sheet print, and probably his best portrait from the life. He also engraved two views of "Cambridge;" a whole sheet view of "King's College Chapel" in that university; several views of public Buildings at Oxford; and eleven plates of the "Habits of the Academics" at that university, which are entitled, "Habitus Academicorum Oxoniæ a Doctore ad Servientem;" and had (what seems an odd thing) a licence for fifteen years for vending his "Oxonia Illustrata."

With David Loggan came over from Holland Abraham Blooteling and Gerard Valek, men of superior talents, though probably of inferior address. Vertue informs us, that whilst in England, Blooteling received thirty guineas (a large price in those days) for an etching of the duke of Norfolk. His powers were various: he etched, engraved, and scraped in mezzotinto. His etchings are spirited and free; and his mezzotintos of a clear grain, and tolerably well drawn. About eighteen of his portraits are enumerated by Vertue, of which the principal are, "Anthony earl of Shaftesbury," one of the scarcest of Blooteling's works; and "Prince Rupert," after sir P. Lely. The portrait of "Admiral Kortenaar," a large upright, from Bartholomew Vander Helst, is not among those mentioned by Vertue.

After remaining some few years in England, Blooteling returned to Amsterdam; and in the year 1685, published there the "Gems of Leonardo Augustino," from plates etched by himself.

Gerard Valek was originally Blooteling's servant, (perhaps apprentice,) but afterwards married his sister. Some of the best engravings, or best parts of those engravings, which were published in the name of Loggan, are probably the performances of Valek, who also assisted Peter Schenck in his large Dutch Atlas, published in 1683. Lord Orford says, that he "engraved one of the finest prints we have: it is the famous "Duchess of Mazarine," sitting in very loose attire, with one hand on an urn;" but this praise is more than the engraving deserves. His other works are, a "Bathsheba bathing," from B. Graat; and the portraits of "Robert Lord Brooke," and "John Duke of Lauderdale." Vertue knew of no other plates that were entirely engraved by Valek.

Notwithstanding the "Sculptura" of Evelyn, and the merits of Hollar, Barlow, Faithorne, and the engravers of the Vandyke school, the tastelessness and dissolute manners of the court of Charles II. had now reduced the art of engraving to a very low ebb. Its records are scarcely more than those of the commonest trade.

Edward le Davis was of Welsh extraction, and, having some inclination for the arts, was articleed as an apprentice to David Loggan. Being maltreated by his mistress, who obliged him to wear a livery, and follow her as a servant, he absented himself, went over to France, and became a dealer in pictures. On his return he drew and engraved several portraits, and some other subjects; but their merits are inconsiderable. Vertue mentions the names of nine of these portraits,

## ENGRAVING.

portraits, of which the most remarkable are, "King Charles II." seated, whose face was afterwards erased from the copper, and that of William III. substituted in its stead; "Queen Catherine of England," a large whole length; and "James Duke of York," a large head in an oval, surrounded by flowers. Le Davis also engraved an "Ecce Homo," after Caracci, which is become scarce; and "a Merry Andrew," after Frank Hals.

About the same time with Blooteling, Michael Burghers was also driven hither by the troubles in the United Netherlands, and settled at Oxford. His works are executed entirely with the graver, in a stiff, laboured style: and his drawing of the human figure very defective. The most valuable of his engravings are the antiquities, consisting of ancient pavements, ruined monasteries, &c. which he executed for that indefatigable antiquary, Thomas Hearne. Mr. Strutt, speaking of them, says, "though we cannot admire the taste with which they are executed, yet they become estimable, because they still continue to us an idea of those monuments of antiquity, which time had otherwise obliterated for ever."

Excepting these, his best prints are probably a few which he copied from Mellan, wherein he imitated the spiral style of that singular master, and among which are, a large "Face of our Saviour," executed in a single spiral line; and "a Frontispiece" to Creech's translation of the Satires of Horace, a much smaller plate. He also engraved some few of the "Oxford Almanacks," beginning (though the plate appears without his name) in the year 1676, and did several other plates, among which are the old chapel of Queen's college, before it was pulled down, for that learned university; sometimes adding to his name, when he inscribed it beneath his engravings, "Academix Oxon. Calcographus."

Peter Vanderbank was an engraver of more merit. He was born at Paris, though probably of Dutch ancestors, and studied under De Poilly. He arrived in England about the year 1674, and here he married the sister of Mr. Forester of Bradfield, in Hertfordshire. Lord Orford says, he "was soon admired for the softness of his prints, and still more for the size of them; some of his heads being the largest that had yet appeared in England." But softness and admiration are comparative terms; and the reader must not suppose that his portraits are in that respect comparable with those of Nanteuil or Houbraken. Yet the merit of paying more attention than had hitherto been paid in England to the manual part of engraving is certainly his; and this circumstance, added to the large dimensions of many of his plates, occasioned them to occupy so much time, that he was by no means adequately compensated for his labour. After struggling for a time with poverty, print-dealers, and the low taste of the times, he retired without compromising his merits, and found an asylum under the friendly roof of his brother-in-law at Bradfield, where he died in the year 1697.

"After his death, his widow disposed of his plates to Brown, the print-seller, who made great advantage of them, and left an easy fortune."

Vanderbank engraved some plates after Verrio's pictures at Windsor, but by far the greater part of his works are portraits, of which Vertue has enumerated no fewer than fifty! which, considering the large size of some of them, is no trifling evidence of his professional diligence. Those of most importance are, "King Charles II." in his greater robes, after Gaspar, (done the year after Vanderbank's arrival;) another portrait of Charles, two feet four inches high, by two feet wide; "King James II." after sir Godfrey Kneller, large; "Mary

his Queen," ditto; separate plates of "King William" and "Queen Mary;" "Thomas Lamplugh, archbishop of York," which is one of the finest of his works; and two heads of Waller the poet, at the ages of twenty-three and seventy-six.

Arthur Soly, William Elder, John Drapentier, Robert Jackson, Francis Bragge, Paul Vanfomer, Nicholas Yates, John Collins, Simon Gribelin, William and John Clarke, and R. Tompson, who all lived and engraved about the time now under our observation, are unworthy of particular notice. "The art of engraving," says Vertue, "had sunk so low about the close of the century, that Verrio, Cooke, and Laguerre, could find no better artists to engrave their designs than Gribelin and Vanfomer." "He might in justice have added," observes lord Orford, "that the engravers were good enough for the painters."

Of Robert White, who was born in London in the year 1645, and died in 1704, little more can be said, except on the score of his drawings in black-lead, and his professional industry, which, judging from the number of his engravings, may well excite our surprize. Vertue praises his portraits more than they will be found to deserve as engravings. Yet all his biographers agree that the merit of producing a strong likeness was certainly his, and in portrait engraving this is the first of merits.

The president of the Royal Academy (Mr. West) is in possession of some of his pencil drawings on vellum, which are superior to his prints; and sir Godfrey Kneller thought so well of them, that he painted White's portrait in return for drawings of his own and his brother's, from the hand of the engraver. The reader will find White's portrait of sir Godfrey in Sandrart's lives of the painters.

From David Loggan he learned the rudiments of engraving, and in the year 1674, which is two years before Burghers was employed on the "Oxford Almanack," White produced the first of that series.

For the generality of his portraits for books, which are disfigured by the broad borders that were then the fashion, he received at the rate of four pounds each, with the occasional addition of ten shillings; thirty pounds, which was paid him by Mr. Sowters of Exeter for a portrait of the king of Sweden, (which the present writer has not seen, but which was probably of much larger dimensions,) has been spoken of as an extraordinary price. So great, however, is the number of his engravings, that in the course of forty years he saved from four to five thousand pounds; and yet, say his biographers, (with little reflection copying each other,) by some misfortune or sudden extravagance, he died in indigent circumstances at his house in Bloomsbury. The reader, probably, will not readily believe, that the habits acquired by the patient professional industry of forty years, could plunge into sudden extravagance.

Of his own works he made no regular collection, but when he had done a plate, rolled up two or three proofs, and flung them into a closet, where they were found in heaps. Many of these proofs may now be found in the collections of those curious persons who take Grainger for their guide.

The plates which he had by him were, after his decease, sold to a printseller in the Poultry, who in a few years, according to lord Orford and Mr. Strutt, enriched himself by the purchase. Vertue expresses his honest displeasure that so large a portion of the produce of our engraver's industry should devolve to the dealer; but so it has ever been: and if he complains for White, how loudly should he complain for Milton!

The number of his portraits of which Vertue has collected the names, are two hundred and seventy-five, of which,

## ENGRAVING.

which, two are scraped in mezzotinto, and all the rest engraved in lines. Some few of Robert White's plates are finished by his son George, who chiefly practised in mezzotinto, but engraved a few plates in lines, of which the principal one is a large portrait of "James Gardiner," bishop of Lincoln.

John Sturt, the pupil of White, who was born in London in the year 1658, and lived to the age of seventy-two, was a man of ignorant ingenuity. His principal work is the "Book of Common Prayer," which he engraved on silver plates. The top of every page is ornamented with a small historical vignette. Prefixed is the bust of George I. in a circle, and facing it the prince and princess of Wales. The peculiarity of this work is, that the lines of the king's face are expressed by writing, so small that few persons can read it without a magnifying glass, and that this writing consists of the Lord's prayer, the Ten Commandments, prayers for the royal family, and the 21st Psalm. So that here are prayers which cannot be read, and a head which might have been better produced with a hundredth part of the labour. This uncommon Common Prayer Book was published by subscription in London in the year 1717. It was in large octavo, and was followed by a "Companion to the Altar" of the same size, and executed in the same manner. Sturt was also the first man who posed the wondering multitude of "microscopic wights," by engraving the Lord's Prayer within the area of a circle of the dimensions of a silver penny.

To this wonder-niggling state was engraving reduced, when, at the commencement of the new century, sir Nicholas Dorigny shone forth on the darkened arts of England. He was born in France, and was a younger son of Michael Dorigny, by a daughter of Vouet the painter. His father dying whilst he was young, he was brought up to the study of the law, which he pursued till he was about thirty years of age: being then examined, in order to his admission into the corps of advocates, the judge found him very difficult of hearing, and accordingly advised him to relinquish a profession for which he was in this respect so ill qualified by nature. He took the advice, and immediately applied himself to drawing with great assiduity. After a year's experience in this art he repaired to Rome, where his brother at that time resided, and here he followed painting for some years; when, having acquired great freedom of hand, and being uncommonly docile and flexible in his disposition, he followed the recommendation of certain friends, who advised him to study etching. In this art he produced several works of merit, but the engravings of Audran, which were now the topic of general and just encomium, convinced him that the style he had adopted was susceptible of great improvement; and he employed *ten years* in emulating the vigour and grandeur of that distinguished artist. He had now etched many plates, and among them the series from the fable of "Cupid and Psyche," after Raffaele, when, feeling that he had not acquired that command of the graver which was necessary to the harmonious perfection which he contemplated, he abandoned engraving for a short time and returned to his pencils. "A word from a friend," says lord Orford, "would have thrown him back to the law:" this, however, it is not easy to believe.

After two months re-application to painting, he resolved to acquire that power over the graver, of which he had so strongly felt or fancied the necessity. All these feelings and resolutions are those of an artist of genius. With a little instruction, he rapidly acquired the knowledge and power of which he was in quest, and begun to engrave the set of "Seven Planets," after Raffaele; in which he

succeeded so well, that he was now emboldened to undertake Raffaele's "Transfiguration," the accomplishment of which raised his reputation to an extraordinary height.

Being known to several English noblemen and gentlemen of rank, who at that time resided in Italy, he was persuaded to come to England, and undertake to engrave the Cartoons. He arrived in June 1711, but experienced some disappointment, and was not enabled to begin his drawings till the year following, the intervening time being spent in raising a fund to enable him to prosecute his intended work.

At first it was proposed that the plates should be engraved at queen Anne's expence, and that the impressions should be given as presents to the nobility, foreign princes, ministers, &c.; but this was too liberal even for what has been emphatically called the Augustan age of England, which had now commenced. Dorigny estimated the expences at four or five thousand pounds, but though the lord treasurer Orford exerted himself greatly in the cause of the artist, he could not obtain the sum, and this plan was consequently rendered abortive.

The engraver had, however, an apartment assigned him in Hampton Court palace, and the work was at last undertaken by a public subscription, at four guineas the set.

The labour of seven plates of the large dimensions that were resolved on, appearing too great for the hand of a single individual, who was not young, Dorigny was induced to send to Paris for assistance; and for the first two or three years obtained that of Dupuis and Dubosc, who both quitted him before the engravings from the Cartoons were half completed.

In somewhat less than seven years, however, from the date of his arrival, (namely, on the 1st day of April, 1719,) Dorigny had the honour of presenting two complete sets of these celebrated engravings (with an engraved dedication) to king George I., one set to the prince, and another to the princess, when he received from his majesty a purse of a hundred guineas, and a medal from the prince; and the duke of Devonshire, of whom he had borrowed four hundred pounds, freely remitted the interest for four years. His reputation from this time continued to increase through Europe, and in the year following, he received the further honour of knighthood from the hand of his majesty.

In a few years after the completion of the Cartoons, the eyes of our engraver began to grow dim, and either this circumstance; or the natural inclination of man to return to the place of his nativity, occasioned his return to Paris, where, in the year 1725, he was made a member of the Royal Academy of Arts, and where he died at the advanced age of eighty-nine.

His drawings from the old masters, chiefly after Raffaele, Dominichino, Guercino, and Daniel de Volterra, have been much admired, and have sold for considerable sums; and besides the plates mentioned above, he engraved "St. Peter curing the lame Man," a large upright from Civoli, which is one of his early works, and in the dark manner of his father; "The Descent from the Cross," after Daniel de Volterra, a very fine engraving; the "Martyrdom of St. Sebastian," after Dominichino, an upright, and equally meritorious; "The Holy Trinity," from Guido; and a few other plates from A. Carracci, Lanfranc, and Louis Dorigny, his brother.

When the late period of life at which Dorigny began to use the graver is considered, the power which he acquired over that instrument must be regarded as extraordinary: the art with which he mingled the lines of the graver with those of the etching-needle is also much to be admired; and though it must be allowed that in copying Raffaele's

## ENGRAVING.

forms he has often lost much of their exquisite grace and chasteness, and has rendered the characters of his heads but coarsely, yet on the whole he rides his graphic Pegasus with masculine grace. There is a manly energy and freedom in his style, bridled by simplicity; his shadows are full-toned, clear, and rich; and though his flesh be deficient in characteristic texture, the lines are often conducted over his draperies with unprecedented freedom and elegance, of which the figure of "St. Paul preaching at Athens," and that of the same apostle in the Cartoon of "Elymas the forcerer, struck blind," may be sufficient examples. Indeed, a critical eye may trace in the arrangement of Dorigny's lines, the rudimental principle of that simple system of drapery-engraving, which Mr. Heath and his school have since polished and rendered more perfect.

Charles Dupuis, who has been mentioned as the assistant of Dorigny, engraved some plates from the history of the misfortunes of Charles I., but the climate of England not agreeing with his constitution, he returned to Paris, and died there in the year 1743. A younger brother of his also came over, but returned in disappointment, finding British encouragement less than he had expected.

Claude Dubosc quitted Dorigny's service at the same time with Dupuis, but settled here, and, with more boldness than ability, undertook to engrave the Cartoons on a smaller scale than Dorigny's for the printfellers, who presumptively, were *cunning* enough to think, not of transcribing, but of *underjelling* the engravings of that distinguished artist. He next engaged himself to engrave a set of the duke of Marlborough's battles, for which he received at the rate of four-score pounds *per* plate. At first he had no assistance but what he received from du Guernier, but afterwards sent to Paris for Beauvais and Baron, who assisted him in the completion of these engravings. He now commenced printfeller, and published in numbers a translation of Picart's "Religious Ceremonies," in engraving which, he was assisted by Gravelot and Scotin, who came over to England for that purpose.

Dubosc's style of engraving is heavy, and his drawing of the naked very indifferent, which renders it not improbable that the worst parts of Dorigny's Cartoons are by his hand. Among his works, which are not very numerous, the "Contiaence of Scipio," from that picture of Nicholas Poussin, which was in the Houghton Collection, is probably the best.

Of the Winstanleys, as engravers, little can be said. Henry (the elder) etched several views of "The Palace at Audley-end;" and Hamlet (son of the former) etched twenty plates from the earl of Derby's Collection, and a set of prints from sir James Thornhill's "Cupola of St. Paul's Cathedral."

The father was projector and builder of the Eddystone light-house, and when it was thrown down by a dreadful tempest, was buried in its ruins. To his etchings of Audley-end, which were dedicated to king James II., he added an inscription in honour of sir Christopher Wren, and the plates being "reserved by the descendants of the earl of Suffolk," (according to lord Orford,) the impressions are now become scarce.

The son studied under the Knellers, and afterwards in Italy, yet he made no great figure as an artist. The nobleman quoted above, speaks of his house at Littlebury, where "were several mechanic tricks to surprize the populace, which were known by the name of "Winstanley's Wonders." These childish contrivances, I suppose, he learned in Italy, where they do not let their religion monopolize *all* kinds of legerdemain. In the noble palace of the villa

Borghese," adds his lordship, "was the noble statue of Seneca dying in the bath, and a devil that started out of a clock-case as you entered the room." Hamlet painted a few portraits with moderate ability.

The assistance which du Guernier rendered to Dubosc in his "Battles of the Duke of Marlborough," has been already mentioned. He studied under Chatillon, at Paris, and came to England in 1708. The London Academy, as it was called, was then establishing under the auspices of sir Godfrey Kneller, and du Guernier was chosen director of it, and continued to to the time of his death, which was occasioned by the small-pox, and happened Sept. 19, 1716, when he was but thirty-nine years of age. Besides his share of the Marlborough's battles, he engraved a few frontispieces, chiefly for plays, and, at the instance of lord Halifax, a large print of "Lot and his Daughter," from Caravaggio, and the portraits (large) of the "Duke and Duchels of Queensbury."

Bickham, Coignard, Johnson, George King, Nichols, and Simpson, who were all contemporary, are passed over for reasons which have formerly been given. John Kip engraved a considerable number of the palaces and seats of the nobility and gentry from Knyff, but they were indifferent, and were far from advancing the art.

It has been already mentioned, that Girard Scotin, the younger, came over from Paris to assist Dubosc. He studied under his father, who was an engraver and a disciple of De Poilly, but was a man of more industry than talent. His principal works are, "Belisarius," a large plate, after Vandyke, or Murillo, for it does not appear to be ascertained to which of these masters this celebrated picture should be ascribed; and "Alfred receiving the Account of the defeat of the Danes," from Blakeney. He also assisted Hogarth in some of his series, and engraved a few portraits.

Henry Gravelot, who came hither at the same time, was an artist of much more taste. His opportunities of observing nature had been more various and extensive than fell to the lot of many of his contemporary professors of the fine arts. He was a native of France, but had been in America as secretary to the governor of Canada: the climate disagreeing with him, he returned to Paris, whence he was invited to England by Dubosc.

He was for some time employed in Gloucestershire, drawing churches and antiquities, and, according to lord Orford, he drew the monuments of kings for Vertue. For the booksellers he made a very great number of designs, both historical and ornamental, wherein his taste and the fertility of his inventive powers are eminently conspicuous. From many of these he made etchings, as also many after the designs of Hayman, and the same taste and facility attended his etching-needle, which is conspicuous in the productions of his pencil.

In sir Thomas Hanmer's and Theobald's editions of Shakespeare, a great number of his engravings, and several of his designs, may be found. His principal work on copper is a large print of "Kirkstall Abbey," which Strutt speaks of as a fine specimen of his abilities, but which the present writer has not seen. He lived to the age of seventy-four, and died at Paris in the year 1773.

Bernard Baron was also transplanted hither from the continent by Dubosc, who appears to have been a great speculator in this species of culture. They differed, and went to law, on the subject of a set of engravings after Dr. Mead's pictures from the history of Ulysses, by Rubens, but were afterwards reconciled, and went to Paris together in the year 1729. After engraving some plates for Mous-

Crozat,

## ENGRAVING.

Crozat, from the royal collection, he returned to England, and here he executed a considerable number, and had the satisfaction of working after some of the finest pictures in the kingdom.

His style is chiefly studied from that of sir Nicholas Dorigny, generally coarse, but occasionally somewhat softened and incorporated with the prevailing taste of the French school. His principal engravings are as follow, and are all large plates. "Vandyke's equestrian figure of Charles I." from the royal gallery at Kensington; the "Cornaro family," from the celebrated Titian at Northumberland house; the "Pembroke family," from the same master, at Wilton house; the "Nassau family," from the same, in the collection of earl Cowper; the "Jupiter and Antiope," also after Titian, executed in Paris; "Henry VIII. granting the charter of incorporation to the company of Surgeons" from Holbein. Baron died in Panton square, Piccadilly, in the year 1762.

Chereau, the younger, was also imported from Paris by Dubosc, and engraved a profile likeness of George I. which possesses some merit, but finding or fancying, that his talents were undervalued in England, he soon returned.

Michael Vandergucht, originally of Antwerp, studied under Boutats, but was the master of Vertue. The year of his arrival in England is not known: here, however, he met with some encouragement, and resided in London. His chief employment was to engrave anatomical figures, but he sometimes undertook subjects of a different kind. His master-piece, according to Vertue, was a portrait of Mr. Savage. He also engraved a very large plate of the royal navy from Baston.

John Vandergucht, son of the preceding, was born in 1697, and acquired from his father the manual practice of engraving, but studied drawing under Lewis Cheron, and afterwards at the London Academy. He was employed by Chefelden to draw and engrave the subjects for his Osteology, a work by which he obtained much credit; and he had a considerable sum for engraving "Sir James Thornhill's cupola of St. Paul's cathedral." The six academy figures which he engraved from the drawings of his master Cheron, shew that he understood drawing better than he could manage the graver. He also engraved Poussin's "Tancred and Erminia."

He produced a great number of book-plates, of which the merits were not great, and some were also engraved by his brother Gerard Vandergucht, who was a great dealer in pictures, lived to the age of eighty years, and died in 1778 at his house in Brook-street, the same that is now inhabited by Tresham the academician.

George Vertue was born in the year 1684, in the parish of St. Martin in the Fields, London, and was put apprentice at the age of thirteen to a master who engraved heraldry on plate. This person being obliged to leave the kingdom by the time Vertue had been three or four years under him, our artist returned to his parents. He then gave himself entirely to the study of drawing for two years, when he became the pupil of Michael Vandergucht; with whom he engaged to remain three years, but protracted his stay to seven, when he quitted his master on handsome terms, and began to engrave book-plates for himself.

"The art was then, says lord Orford, at the lowest ebb in England. The best performers were worn out; the war with France shut the door against recruits; and the animosity of faction diverted public attention from the common arts of amusement." At this period our young engraver was recommended to the notice of sir Godfrey Kneller, whose reputation sustained the remaining dignity of art:

Kneller befriended him, and he was soon after employed by lord Somers, who, according to Strutt, "rewarded him generously," and by his talents and industry he was now enabled to support his widowed mother, with her family of several children.

In the year 1711 he began to study at the academy which sir Godfrey had recently instituted; where he continued to draw for some years with great assiduity. He had now produced his famous head of archbishop Tillotson, which lord Orford emphatically calls "the ground-work of his reputation," and soon after the accession of the present royal family, he published a large portrait of king George I. from a picture by Kneller. "As it was the first portrait of that monarch, many thousands were sold, though by no means a laborious or valuable performance. However it was shewn at court, and was followed by his undertaking to engrave portraits of the prince and princesses."

Vertue had now commenced those biographical and antiquarian researches, in which he has been so eminently successful. In these pursuits he made many journeys to different parts of our island, and his time was industriously employed in making drawings, catalogues, and various memoranda.

"His thirst after British antiquities soon led him to a congenial Mæcenas. That munificent collector, Robert Harley, second earl of Oxford, distinguished the merit and application of Vertue;" and the invariable gratitude of the latter, expressed on all occasions, attests at once the bounty of his patron and his own humility.

Another of his patrons was Heneage Finch, earl of Winchelsea, whose portrait he painted and engraved, and who, being president of the Society of Antiquaries on its revival, in 1717, appointed Vertue, who was a member, engraver to that learned body.

Henry Harc, the last lord Coleraine, was also one of his antiquarian benefactors, and the university of Oxford employed him for many years to engrave the head pieces for their almanacks.

With lord Orford, lord Coleraine, and Mr. Stephens the historiographer, he made several tours to various parts of England. For the former he engraved portraits of "Matthew Prior," "sir Hugh Middleton," and other distinguished men: for the duke of Montague he engraved, "sir Ralph Windwood;" for sir Paul Methuen, the portraits of "Cortez," and "Archbishop Warham" from Holbein's original at Lambeth; and for lord Burlington, Zucchero's "Queen Mary of Scotland," a plate which evinces more felicity, and a better taste of execution, than most other of his works.

In the year 1727 he travelled with lord Orford to Burreleigh, Lincoln, Welbeck, Chatsworth, and York, at which latter place he obtained from Francis Place, whom we have mentioned, many of those anecdotes of Hollar which are inserted in his biography.

In the next year, the duke of Dorset invited him to Knowle. From the gallery there, he copied the portraits of several of the poets. Here he was on fairy ground, and Arcadia was on the confines; but he was disappointed on an excursion to Penshurst, at not finding there any portrait of sir Philip Sydney.

In 1730 appeared his twelve heads of distinguished poets, one of his capital works, which he meant to have followed with the portraits of other eminent men, arranged in classes, but this scheme was taken out of his hands by the Messrs. Knapton; and there is reason to think that Vertue's rigid regard for veracity, which made him justly scrupulous of authenticating the likenesses of deceased characters without the clearest proofs, and not the superior taste or discernment

of the Knapton's, made them engage the superior talents of Houbraken and Gravelot, to finish a work which our artist had begun, and had himself projected.

His next considerable production was, the portraits of king Charles I. and the loyal sufferers in his cause, with their characters subjoined from Clarendon. But this was scarcely finished, before Rapin's history of England appeared, "a work, (says he,) which had a prodigious run, insomuch that it became all the conversation of the town and country, and the noise being heightened by opposition and party, it was proposed to publish it in folio by numbers, of which thousands were sold every week." The Messrs. Knapton engaged Vertue to accompany it with effigies of the kings and other suitable embellishments, an undertaking which occupied three years of his life. He presented a copy of this work, when finished, richly bound, to the prince of Wales, at Kensington.

He now renewed his topographical journies, accompanied sometimes by the earl of Leicester, sometimes by lord Oxford, and sometimes by Roger Gale the antiquary; and between the years 1734-38, visited St. Albans, Northampton, Oxford, Penshurst, Warwick, Coventry, Stratford, and travelled through the counties of Kent, Sussex, and Hampshire, where he made various sketches, drawings, and notes, always presenting a duplicate of his observations to his patron lord Oxford.

In 1739, he travelled eastward with lord Coleraine, through the counties of Essex, Suffolk, and Norfolk, stopping as usual to make drawings and observations at every memorable church, seat, or other spot congenial to his pursuits. In 1741 he lost his noble friend and patron the earl of Oxford, who died on the 16th of June. But his merit and modesty still raised him benefactors. The countess dowager of Oxford, even, alleviated his loss, and the duchess of Portland (their daughter), the duke of Richmond, and lord Burlington, did not forget him among the artists whom they patronized.

In the year 1749, he found a yet more exalted protector in the prince of Wales, whom he often had the honour of attending, and to whom he sold many prints, miniature pictures, &c.

"He had now reason to flatter himself with permanent fortune. He saw his fate linked with the revival of the arts he loved; he was useful to a prince who trod in the steps of the accomplished Charles, and no Hugh Peters (adds lord Orford) seemed to threaten havoc to the growing collection." But the death of this prince suddenly blasted the hopes of Vertue, and affected him with considerable dejection of spirits, from which, according to his lordship, he never perfectly recovered. He died in the year 1756, and was buried in the cloisters of Westminster abbey.

By the majority of connoisseurs, Vertue's talents as an engraver have been over-rated. He rarely rises above mediocrity, and sometimes sinks below it, yet the present writer must freely declare his surprise when he first saw a good impression of Vertue's print of "Mary Queen of Scotland," after Zuccherò, at the superior merits which it displayed.

A much more copious biography of this artist will be found in the printed works of lord Orford, and also a catalogue of his engravings (amounting to near five hundred!) classed under the heads of "Royal Portraits," "Noblemen," "Bishops," "Poets," "Antiquaries," "Tombs," "Historic Prints," "Coins," "Medals," "Frontispieces," &c. &c. &c.

To all the distinguished notice and patronage with which

Vertue was honoured, and to the repeated praise of lord Orford, who was one of his friends, he was entitled less by his talents as an artist, or native independence of mind, than by his patience and accuracy of research as an antiquary, and as his noble biographer cannot boast of his genius, it might, perhaps, have been thought that he did right to dwell with so much seeming approbation on his diligence and humility; if he had not himself left posterity such abundant room to wish that he had respected genius more, and been less completely satisfied with the blandishments, which plodding mediocrity may with little difficulty acquire.

We now approach the less patronized and more highly respectable name of William Hogarth, upon whose valuable works as painter and engraver, so many volumes might be profitably written. The able pen to which the biography of the former description of artists is confided, will doubtless claim Hogarth as a painter, yet, as he was both by education and long practice an engraver also, he must not here be passed in silence.

In the narrative which he left behind of his own life and opinions, where his philosophy is not less conspicuous than his manly frankness, and where his foresight with respect to the well-being of British art has shewn itself prophetic, he informs us, that he was born in London in the year 1697; that during his infancy he derived uncommon pleasure from shews and mimicry; that an early access to a neighbouring painter drew his attention from play; and that when at school his exercises were remarkable for the ornaments with which they were adorned.

He was scarcely more attracted by art, than driven from literature, which was the profession of his father. "Besides the natural turn I had for drawing," proceeds he, "I had before my eyes the precarious situation of men of classical education. I saw the difficulties under which my father laboured, and the many inconveniences he endured from his dependance being chiefly on his pen, and the cruel treatment he met with from booksellers and printers. It was, therefore, very conformable to my own wishes that I was taken from school, and served a long apprenticeship to a silver-plate engraver.

"I soon found this business in every respect too limited. The paintings of St. Paul's cathedral and Greenwich hospital, which were at that time going on, ran in my head, and I determined that silver-plate engraving should be followed no longer than necessity obliged me to it.

"Engraving on copper was, at twenty years of age, my utmost ambition. To attain this it was necessary that I should learn to draw objects something like nature, instead of the monsters of heraldry, and the common methods of study being much too tedious for one who loved his pleasure, I was led to consider whether a shorter road than that usually travelled was not to be found. I had learned by practice to copy with tolerable exactness in the usual way; but it occurred to me that there were many disadvantages attending this method of study, as having faulty originals," &c. Drawing in an academy, (Hogarth means a school,) though it should be after the life, will not make the student an artist, for as the eye is often taken from the original to draw a bit at a time; it is possible he may know no more of what he has been copying when his work is finished, than he did before it was begun.

"More reasons, not necessary to enumerate, struck me as strong objections to this practice, and led me to wish that I could find the shorter path, six forms and characters in my mind, and instead of copying the lines, try to read the language, and if possible find the grammar of the art, by bring-

ing into one focus the various observations I had made, and then trying, by my power on the canvas and copper, how far my plan enabled me to combine and apply them to practice.

"For this purpose, I considered what various ways, and to what different purposes the memory might be applied; and fell upon that which I found most suitable to my situation and idle disposition.

"Laying it down first as an axiom, that he who could by any means acquire and retain in his memory perfect ideas of the subjects he meant to draw, would have as clear a knowledge of the figure as a man who can write freely hath of the twenty-four letters of the alphabet and their infinite combinations (each of them being composed of lines), and would consequently be an accurate designer.

"This I thought my only chance for eminence, as I found that the beauty and delicacy of the stroke in engraving was not to be learnt without much practice, and demanded a larger portion of patience than I felt myself disposed to exercise. Added to this, I saw little probability of acquiring the full command of the graver in a sufficient degree to distinguish myself in that walk, nor was I at twenty years of age much disposed to enter on so barren and unprofitable a study as that of merely making fine lines.

"I therefore endeavoured to habituate myself to the exercise of a sort of technical memory, and by repeating in my own mind the parts of which objects were composed, I could by degrees combine and put them together. Thus, with all the drawbacks which resulted from the circumstances I have mentioned, I had one material advantage over my competitors, *viz.* the early habit I thus acquired of retaining in my mind's eye whatever I intended to imitate. Sometimes, but too seldom, I took the life for correcting the parts I had not perfectly enough remembered, and then I transferred them to my compositions."

Such parts only of Hogarth's valuable narrative as are to the present purpose, are here extracted. Those who would read the whole are referred to "A supplement to Hogarth illustrated, compiled from his original manuscript by John Ireland," 1798, published for the author by Nicol, and the Messrs. Boydell. Our artist proceeds:

"Instead of burthening the memory with musty rules, or tiring the eyes with copying dry and damaged pictures, I have ever found studying from nature the shortest and safest way of attaining knowledge in art."—"Had I not sedulously practised what I thus acquired, I should very soon have lost the power of performing it."

In a subsequent chapter he says, "in pursuing my studies, I made all possible use of the technical memory which I have before described, by observing and endeavouring to retain in my mind lineally, such objects as best suited my purpose, so that be where I would my eyes were open, I was at my studies, and acquiring something useful in my profession, and thus the more striking objects, whether of beauty or deformity, were by habit the most easily impressed and retained in my imagination. A redundancy of matter being by this means acquired, it is natural to suppose I introduced it into my works on every occasion that I could.

"By this idle way of proceeding, I grew so profane as to admire nature beyond the first productions of art, and acknowledge I saw, or fancied, delicacies in the life, far surpassing the utmost efforts of imitation.

"To return, the instant I became master of my own time, I determined to qualify myself for engraving on copper. In this I readily got employment; and frontispieces to books, prints to Hudibras, &c. soon brought me into the way. But the tribe of booksellers remained as my father had left

them when he died, (about five years before,) which was of an illness occasioned partly by the treatment he met with from this set of people, and partly by disappointment from great men's promises; so that I doubly felt this usage, which put me upon publishing on my own account. But here again I had to encounter a monopoly of print-sellers, equally mean and destructive to the ingenious; for the first plate I published, called "The Taste of the Town," had no sooner begun to take a run, than I found copies of it in the print-shops vending at half price, while the original prints were returned to me again, and I was thus obliged to sell the plate for whatever these pirates pleased to give me, as there was no place of sale but at their shops. Owing to this and other circumstances, by engraving until I was near thirty, I could do little more than maintain myself."

At the age of two and thirty, he married the daughter of sir James Thornhill, and commenced painter of small conversation pieces, which, having novelty, succeeded for a few years, but were afterwards not sufficiently profitable to pay the expences of his family. "I therefore," says he, "turned my thoughts to a still more novel mode, *viz.* painting and engraving modern moral subjects, a field not broken up in any country or any age.

"I thought that both writers and artists had overlooked that intermediate species of subject, which may be placed between the sublime and the grotesque; I therefore wished to compose pictures on canvas, similar to representations on the stage.

"Ocular demonstration will carry more conviction to the mind of a sensible man than all he would find in a thousand volumes; and this has been attempted in the prints which I have composed.

"After having had my plates pirated in almost all sizes, I, in 1735, applied to parliament for redress, and obtained it in so liberal a manner, as hath not only answered my own purpose, but made prints a considerable article in the commerce of this country; there being now more business of this kind done here, than in Paris or any where else.

"The dealers in pictures and prints found their craft in danger, by what they called a new-fangled innovation. Their trade of living and getting fortunes by the ingenuity of the industrious has, I know, suffered much by my interference; and if the detection of this band of public cheats and oppressors of the rising artists be a crime, I confess myself most guilty."

The obtainment of this act, which secures the copy-right of engravings, was certainly a great benefit, not only to artists, but to the public, and even to the print dealers themselves, who now were secured in the possession of any engraved property which they might purchase. The remainder of Hogarth's narrative chiefly respects his profession as a painter, and the incidents of his private life. His reputation was now extending far and wide; he had published his "Harlot's Progress" in six plates, beside many other prints of less importance, which Mr. Ireland has enumerated, and now brought forth his "Rake's Progress" in eight, which are replete with moral lesson and the most pointed satire. Swift about this time wrote

"How I want thee, hum'rous Hogarth!  
Thou, I hear, a pleasant rogue art,  
Were but you and I acquainted  
Ev'ry monitor should be painted:  
You should try your graving tools  
On this odious group of fools, (the Legion Club.)  
Draw the beasts as I describe 'em,  
Form their features, while I gibe 'em."

## ENGRAVING.

In the course of the next year he engraved "The Sleeping Congregation;" "The Distressed Poet," which in its original state represents Pope thrashing the bookfeller Curl, and "The Arms of the Undertaker's Company." He also published a whole length portrait of lady Byron, from a picture of his own, engraved in mezzotint by Faber.

In the year 1737, he produced only "The Lecture." In 1738, he published "Morning," "Noon," "Evening," and "Night." The third plate was engraved by Baron, except the figure of the girl with a fan, which was an afterthought of Hogarth's, and is from his own graver. The "Salisbury" flying coach in the engraving of Night, is thought to be a satire on a certain peer who delighted to drive his own horses. He also produced this year "Strolling Actresses in a Barn;" the original picture of which he sold to Francis Beckford, esq. for 27*l.* 6*s.* who returned it, though charged at so low a price, and it was afterwards sold to Mr. Wood of Littleton for the same sum.

Until the year 1741, he published nothing more, when "The enraged Musician" made its appearance, in which the principal figure has been spoken of as being the portrait of Cervetto, but on better authority, is now supposed to be that of Feslin.

In 1742, he engraved and published the portrait of "Martin Foulkes, esq.," "The Charmers of the Age," (a sketch,) and "Taste in High Life," which latter is replete with the most pointed satire on the reigning follies and fashions which then prevailed in the higher circles. A more sophisticated assemblage of objects cannot be imagined, and the elderly lady of the Chesterfield school, who holds the small Dresden tea-cup with so much exquisite delicacy of fingering, and a countenance so truly expressive of the affectation of intense enjoyment of its beauties, has never been surpassed.

From this time, till the year 1745, he was employed on his "Marriage A-la-Mode," and only published three portraits, engraved by other artists, from his own pictures. The series of six plates of the Marriage A-la-mode were chiefly engraved by Scotin and Baron, who have been already mentioned, and S. Ravenet. Hogarth engraved on the plates from time to time, which has occasioned those variations which certain adorers of rarity look for with more eagerness, than they appear to possess feeling or judgment in estimating the general design. This series comprehends indeed master-pieces of art in their kind, and places Hogarth's fame on the broadest and most durable basis.

In the following year, he etched and published his characteristic portrait of "Lord Lovat," which, by those who have seen him, has been attested to be "in air, character, and features, a most faithful resemblance of the original." He is represented seated in his old fashioned chair with the lofty back, and in the act of enumerating by his fingers the rebel forces. It is etched with uncommon spirit, and what was of more pecuniary importance, (adds Mr. Ireland,) was so well timed, that Mrs. Lewis told me, they for many weeks received more than ten pounds a day from the sale. It was published the 25th August, 1746, and the peer was beheaded the 9th April 1747, in the eightieth year of his age. The portrait of Garrick, in the character of Richard III. engraved by Hogarth, and C. Grignion, was also published this year, of which Mr. Grignion, (who has done so much for an art which has done so little for him, and is still living,) says, that Hogarth etched the head and the hands, but erased the head twice before he could satisfy himself. In the course of the present year Hogarth also issued the subscription ticket to "The March to Finchley."

The series of "The Idle and Industrious Apprentices,"

in twelve plates, designed and engraved by William Hogarth, were published in 1747. Of this series, so replete with moral lesson, and heightened with such admirable strokes of humour, Hogarth himself has written as follows. "The effects of idleness and industry exemplified in the conduct of two fellow-<sup>3</sup>prentices. These twelve prints were intended for the instruction of young people, and, considering the persons they were intended to serve, I have endeavoured to render them intelligible and cheap as possible:" (the twelve were originally published at the low price of twelve shillings.) "Fine engraving is not necessary for such subjects, if what is infinitely more material, *viz.* character and expression, be properly preserved." "The Stage Coach or Country Inn Yard," and two portraits of Gibbs the architect, engraved by Baron and Mc. Ardell, he also published in the course of this year.

In 1748, he etched a view of Mr. Ranby's house at Chiswick, but nothing else of any consequence. In 1749, was produced "The Gate of Calais," or, "Roast Beef of Old England." It appears that soon after the peace of Aix-la-Chapelle, Hogarth went over to France, and as he was sauntering about at Calais, and contemplating the difference between England and France, he observed over the gate of the town some appearance of the arms of England; he was prompted to make a sketch, and being observed, was taken into custody: his own account of this affair is as follows: "Not attempting to cancel any of my sketches or memorandums, which were found to be merely those of a painter for his private use, without any relation to fortification, it was not thought necessary to send me back to Paris." (This word contradicts the assertion of those who say he never went further into France than Calais.) "I was only closely confined to my own chamber till the wind changed for England; where I no sooner arrived, than I set about the picture (of roast beef) and made the gate my back ground; and in one corner introduced my own portrait, which has generally been thought a correct likeness, with the soldier's hand upon my shoulder. By the fat friar, who stops the lean cook that is sinking under the weight of a vast surloin, and two of the military who are bearing off a great kettle of soup maigre, I meant to display to my own countrymen the striking difference between the food, priests, soldiers, &c. of two nations so contiguous, that in a clear day one coast may be seen from the other. The melancholy and miserable highlander, browsing on his scanty fare, consisting of a bit of bread and an onion, is intended for one of the many that fled from this country after the rebellion in 1744." In the course of this year, he also engraved and published his own portrait in a cap, with his favourite pug dog and palette, on which is drawn that mysterious "line of beauty and grace," which excited, and was meant to excite, the attention of the public in no slight degree.

Fourteen years afterwards, Hogarth erased his own head from the plate, and in its place engraved a caricature of Churchill as a bear, and inscribed it, "The Bruifer C. Churchill (once the Reverend!) in the character of a Russian Hercules," &c. &c.

In the year 1750, appeared his "March to Finchley," which was engraved by Luke Sullivan, and dedicated to the king of Prussia. The original picture he presented to the Foundling hospital. "Gin-lane" and "Beer-street" appeared in the following year, of which prints Hogarth himself gives the following account. "When these two prints were designed and engraved, the dreadful consequences of gin drinking appeared in every street. In Gin-lane, every circumstance of its horrid effects is brought to view in ter-

## ENGRAVING.

*rorem.* Idleness, poverty, misery, and distress, which drive even to madness and death, are the only objects that are to be seen; and not a house in tolerable condition, but the pawn-brokers and gin shop."

"Beer-street," its companion, was given as a contrast, where that invigorating liquor is recommended in order to drive the other out of vogue. Here all is joyous and thriving, &c. &c."

He also now published his "Four Stages of Cruelty," of which he has thus usefully, honestly, and proudly written. "The leading points in these, as well as the two preceding prints, were made as obvious as possible, in the hope that their tendency might be seen by men of the lowest rank. Neither minute accuracy of design, nor fine engraving, were deemed necessary, as the latter would have rendered them too expensive to the persons to whom they were intended to be useful: and the fact is, that the passions may be more forcibly expressed by a strong bold stroke, than by the most delicate engraving." (The artist probably meant this observation to be applied to the violent, and not to the tender passions.) "To expressing them as I felt them, I have paid the utmost attention, and as they were addressed to hard hearts, have rather preferred leaving them hard, and giving the effect by a quick touch, to rendering them languid and feeble by fine strokes and soft engraving, which require more care than can often be attained, except by a man of a very quiet turn of mind. Masson, who gave two strokes to every particular hair that he engraved, merited great admiration, but at such admiration I never aspired, neither was I capable of attaining it if I had.

"The prints were engraved with the hope of, in some degree, correcting that barbarous treatment of animals, the very sight of which renders the streets of our metropolis so distressing to every feeling mind. If they have had this effect and checked the progress of cruelty, I am more proud of having been the author, than I should be of having painted Raphael's cartoons."

The humorous "Paul before Felix" was also the produce of this year, which in the earliest impressions is subscribed, "designed and scratched in the true Dutch taste by William Hogarth," and in the subsequent impressions (where he has introduced a little fiend sawing off the leg of the Apostle's stool,) "designed and etched in the ridiculous manner of Rembrandt by Wm. Hogarth." This whimsical little print was originally given with the receipts to the subscription for the serious "Paul before Felix," and "Pharaoh's Daughter," both of which he produced in the course of the ensuing year.

The former of these he engraved from his original picture in Lincoln's-inn Hall; another plate of which subject, with some variations, was published by Hogarth at the same time, (which is remarkable, both being dated Feb. 5,) engraved by Luke Sullivan.

"Moses brought to Pharaoh's Daughter" is engraved by William Hogarth and Luke Sullivan from the original painting in the Foundling hospital, and was also published on the same day.

His "Columbus breaking the Egg" was given in the November of this year, with the receipt for "the first payment of a short tract in quarto, called the Analysis of Beauty; wherein forms are considered in a new light;" and in the next year came forth his far famed "Analysis of Beauty, written with the view of fixing the fluctuating ideas of taste," and embellished with two folded and very curious illustrative engravings.

With some small literary assistance from Dr. Hoadly, Mr.

Ralph, and Dr. Morell, he here maintained an hypothesis respecting undulating forms as essential to grace and beauty, the merits of which have, by subsequent writers on the subject of taste, been variously estimated, but of late have been utterly denied by Mr. P. Knight, who (in his analytical enquiry into the principles of taste) says, that the qualities of ease, grace, elegance, &c. do not "consist in any lines of beauty, or depend upon the impressions which any specific forms make on the organs of sight. On the contrary, they arise wholly from mental sympathies and the association of ideas."

An impression from the first plate of the Analysis of Beauty, which is in the possession of Mr. G. Baker, has this singularity, that the words "et tu Brute," are engraved on the pedestal on which stands Quin in the character of Brutus, which were afterwards erased.

In the year 1754 his admirable satire on parliamentary elections, which was engraved on four plates, began to appear. Of the first plate, which is "An Election Entertainment," it has been said that Hogarth completed the engraving without taking from it a single proof by which to ascertain the progress of his work. It might be so, but if this were wise it would more frequently be practised, and Hogarth himself is known to have repented of his imprudence when a proof was taken.

This performance, in its original state, is by far the most finished and carefully executed of Hogarth's engravings, and he therefore, conscious of the superior pains which he had bestowed on it, inscribed beneath it, "painted, and the whole engraved by Wm. Hogarth," but these two words were afterwards erased, for the number sold was so considerable, that by the time the second plate of this series made its appearance, the first had been touched and retouched so often, that all the original and delicate lines were either hidden by others, or utterly obliterated, and it has been compared, wittily enough, to sir John Cutler's stockings, which, from frequent mending, from silk degenerated into worsted.

The second of the election series, of which the subject is "Canvassing for Votes" is engraved by C. Grignion, and was published in the year 1757. On which occasion Hogarth apologized in the public prints for the delay which had taken place, ascribing it to the difficulty of procuring able hands to engrave the plates. In the early impression this is an excellent engraving.

The third plate of this series is entitled "The Polling," is engraved by Hogarth and Le Cave, and was published in the following year.

The fourth plate, which completes the series, and is entitled "Chairing the Members," was also published in the course of the year 1758, and is engraved by Hogarth and Aveline.

In all these plates the satire of Hogarth is most poignant and abundant; and notwithstanding the number of portraits our engraver has introduced, his meaning is so general, that the election-prints continue to be applicable to the present time.

In the year 1758 he also engraved and published "the Bench," with explanations and illustrations of the words, "character" and "caricature." The print exhibits the inside of the court of common pleas, over which is the king's arms, and beneath are the portraits of the following judges, viz. honourable William Noel, sir John Willes; the lord chief justice; honourable Mr. justice (afterwards lord) Bathurst, and sir Edward Clive.

His own portrait, a whole length figure, was also the produce of this year, in which plate the face-only is engraved

## ENGRAVING.

graven by Hogarth. He has here represented himself in profile, sitting, with a cap on his head, and engaged, in a very appropriate manner, in painting the muse of comedy. His analysis of beauty lies on the floor, and underneath is his title of serjeant painter to his majesty. It may be observed of this likeness, and that which he has introduced in his "Gate of Calais," that they both correspond much better with the bust of Hogarth, which was modelled by Roubilliac, and is now in the collection of M. G. Baker, than the three-quarter face which was published in 1749, and afterwards metamorphosed to that of Churchill the poet.

"The Cockpit," designed and engraved by W. Hogarth, was produced in 1759. In this engraving is introduced a portrait of Nan Rawlins, a very ugly old woman (commonly called Deptford Nan, and sometimes the duchess of Deptford), who is well remembered at Newmarket. She was a famous cock-feeder, and did the honours of the gentlemen's ordinary at Northampton. The figure with the hump back is that of Jackson, a once noted jockey, and the blind president is lord Albemarle Bertie, who constantly attended this refined and elegant diversion.

In the next three years he produced nothing of his own engraving, though he made some designs from Trilram Shandy; one for Brook Taylor's perspective, and a few others, which were engraved by Woollett, Ravenet, and Grignon: but in 1762, he produced his "Credulity, Superstition, and Fanaticism," which is chiefly meant to ridicule certain methodistical sectaries, and is preferred by lord Orford to all his other works "for deep and useful satire."

"The Times" was also produced in the year 1762. This is a political print, which Mr. Nichols explains as follows: "Europe on fire; France, Germany, and Spain, in flames, which are extending to Great Britain. This desolation continued and assisted by Mr. Pitt under the figure of king Henry VIII. with bellows encreasing the mischief which others are striving to abate. He is mounted on the stilts of the populace. A Cheshire cheese depends from his neck with 3,000*l.* on it. This alludes to what he had said in parliament, that he would sooner live on Cheshire cheese and a shoulder of mutton, than submit to the enemies of Great Britain. Lord Bute, attended by English soldiers, sailors, and highlanders, manages an engine for extinguishing the flames, but is impeded by the duke of Newcastle with a wheel-barrow full of monitors and North Britons, for the purpose of feeding the blaze. The respectable body under Mr. Pitt are the aldermen of London worshipping the idol they had set up; whilst the musical king of Prussia, who alone is sure to gain by the war, is amusing himself with a violin amongst his miserable country women. The picture of the Indian alludes to the advocates for retaining our West Indian conquests, which it was said would only increase excess and debauchery. The breaking down of the Newcastle arms, and the drawing up the patriotic ones, refer to the resignation of that noble duke, and the appointment of his successor. The Dutchman smoking his pipe and a fox peeping out behind him and waiting the issue; the waggon with the treasures of the Hermione; the unnecessary marching of the militia, signified by the Norfolk jigs; the dove with the olive branch, and the miseries of war, are all obvious, and perhaps need no explication."

In 1763, he published a caricature of "John Wilkes," esquire, drawn from the life, and etched in aquafortis by William Hogarth. To which was ironically added "this is a direct contrast to the print of Simon lord Lovat."

Of this caricature, Wilkes with his usual good humour

has been heard to say, that he was every day growing more and more like his portrait by Hogarth.

In the same year was published also, "the Bruiser C. Churchill," which has been already mentioned, and which neither added to his fame, nor in its consequences to his happiness.

"The Bathos," published in 1764, was his last engraving of any consequence, if not his very last work. In the month of October of this year being seventy-four years of age, he departed this life, and was buried in the church yard of Chiswick, where a monument, with an excellent epitaph by Garrick, is erected to his memory.

His engravings, like the tenour of his life, are characterized not by delicacy, but by strength of thought and expression. He did not aim at captivating by the beauty of his art, but at excelling by the power which he possessed of combining a number of particular and congenial truths into one impressive whole: agreeably to his own declarations, we perceive in his prints, that he discovers little dexterity in the arrangement of his lines, and still less solicitude about their beauty: yet in his pictures, and especially in those of the Marriage A-la-Mode, now in the collection of J. J. Angerstein, esquire, are some passages which no Dutch painter and no other painter could have more exquisitely touched. No artist whatever, and scarcely any man more than Hogarth, deserves the praise of original and independent thinking. His engravings are in some instances taken from no pictures, and his pictures from no books. Without having recourse to history or poetry he *invented* his subjects. The world of moral art "was all before him where to choose:" he marked out and took possession of an ample province for himself, replete with the riches of nature; a province which few have since dared to invade, and to which none have disputed his title.

Luke Sullivan, who has been already mentioned, was Hogarth's most valuable coadjutor in engraving: He was a native of Ireland, an eccentric character, and much addicted to women. Whilst engraving the march to Finchley (according to Mr. Ireland,) "Hogarth held out every possible inducement to his remaining at his house in Leicester square night and day; for if once Luke quitted it he was not visible for a month." If Hogarth gave him but one hundred pounds for this plate, as his biographers say, Sullivan's inducements to stay at home were certainly strong.

Beside what he did after Hogarth, Sullivan engraved "the Temptation of St. Anthony," after Teniers, and several garden scenes and other landscapes, which he drew from nature with some ability. He also painted miniatures with success. His own portrait may be seen in the character of an angel, in Hogarth's humorous print of "Paul before Felix." He died of a consumption in the year 1750.

About this time John Pine, whose portrait Hogarth painted in the manner of Rembrandt, was in good repute, but the years of his birth and death are uncertain. His chief works are, "the Ceremonies used at the revival of the order of the Bath;" "The Destruction of the Spanish Armada," from the tapestry of the house of lords; a splendid edition of Horace, illustrated with copies of antique bas-reliefs, gems, coins, &c. and a print of the house of commons.

The pastorals and Georgics of Virgil were published by his son after his death, adorned in the same manner as the Horace, but printed with letter-press types.

Now also flourished Arthur Pond, another native of England. He etched several portraits with freedom, taste, and spirit, among which are those of Mr. Pope (an excellent likeness), lord Bolingbroke, Dr. Mead, and himself. He

## ENGRAVING.

was concerned with the Messrs. Knapton in publishing the volume of portraits of illustrious men which were engraven by Houbraken, Vertue, Gravelot, &c. and in promoting other meritorious works, particularly a set of plates from the great Italian masters in imitation of chalk and bistre drawings, which he accomplished with great success. He also etched a set of caricatures from the chevalier Ghisli, and a few landscapes, chiefly after Rembrandt.

Simon Francis Ravenet was another of Hogarth's occasional coadjutors. He was a native of France, came into England about the year 1750, and settled in London. In the latter part of his life he resided at Mother Red Cap's, near Kentish Town, where he died in 1774. He was of an amiable disposition and much respected, and had the honour of instructing both Ryland and Hall in the art of engraving.

The shadows in his engravings are deep toned, and his style both of drawing and engraving vigorous, though somewhat mannered. Beside what he produced after Hogarth, the following are esteemed among his best prints: "The Prodigal Son," (a large upright) from Sal. Rosa; "Lucretia deploring her Misfortune," from A. Cafali; "The Manifestation of the Innocence of the Princess Gunhelda," (its companion) from the same; "The Death of Seneca," (a large plate) from Lucca Giordano; "The Arcadian Shepherds," from N. Poussin; "The portrait of Lord Camden," from sir Joshua Reynolds. He is also the author of a considerable number of vignettes, book plates, and small portraits.

William Wynne Ryland was born in London in the year 1732. His genius for the fine arts manifested itself at an early period of his life, and he was accordingly placed under Ravenet. At the expiration of the term of his engagement he went to Paris, at that time the chief seminary of engraving, for improvement; and remained there five years.

Under the guidance of Boucher, who at that time led the fashion in art, he applied with great assiduity to the study of drawing, but did not neglect to improve himself also in the practical part of engraving. From the designs of this principal misleader of the taste of France, Ryland engraved several plates, of which the principal and probably the best engraving he ever performed, is rather a large work, of which the subject is "Jupiter and Leda."

He has here displayed great power as an engraver in lines. The print has a fine transparent tone; he has tempered the slimy touchiness of the French taste with a portion of Ravenet's solidity; the soft firmness of flesh is ably characterized in the figure of Leda, and the delicacy of the swan, and various textures of the surrounding objects, are rendered with much feeling and judicious subserviency to the principal parts.

In one of his amatory poems, M<sup>r</sup> Kenzie emphatically exclaims, "Alas! are there fashions in love!"—Alas! there are also fashions in fine art. Unmeaning glitter, unprecedented softness, unprincipled novelty, shall sometimes set aside for a while the truth and simplicity of nature, and the approbation of ages.

It was not, however, the false taste of Boucher that turned aside Ryland's talents from the mark at which he was evidently and successfully aiming, when he produced his "Jupiter and Leda," but a fashion of stippling which he learned in France, and introduced, with his own modifications, into England. Stippling with the graver had been occasionally practised both by Martin Schoen and Albert Durer in the very infancy of the art: the latter employed it in imitating the soft texture of beaver hats, as well as on

some other occasions. Perceiving that it was peculiarly expressive of softness, Agoltino Veneziano and Boulanger sometimes stippled their flesh, and Julio Campagnola his back grounds also. Almost a century afterward it was observed by De Marteau, who was now living, that by etching some of the dots of which this kind of engraving consists, and engraving others, very successful imitations of drawings hatched with chalk, might be produced. But Ryland employed stippling, so as rather to imitate such drawings as are stumped than such as are hatched with chalk, by which means he softened down all energy of style, and has left posterity to regret the voluntary emasculation of the powers he had manifested in the engraving, which is the subject of the above comments.

Soon after his return to England, he, however, engraved in lines a portrait of the queen, after Coates, and that portrait of his majesty, after Allen Ramsay, which Strange, from a misunderstanding either with the earl of Bute or Ramsay, had declined, but they possess neither the vigour nor taste of his "Jupiter and Leda." From this time he was appointed engraver to the king, and received an annual salary.

His subsequent engravings, in the chalk manner, are chiefly after Angelica Kauffman, and consist of four half-sheet circles, of which the subjects are, "Juno obtaining the Cestus of Venus," "A Sacrifice to Pan," "Cupid bound," and "Cupid asleep;" "Queen Eleanor sucking the poison from the wounded Edward I.;" (an excellent engraving of the kind;) "Lady Elizabeth Grey soliciting the restoration of her Lands;" "Maria;" from Sterne's Sentimental Journey, and "Patience," both upright ovals; also "King John ratifying Magna Charta." The last plate being left, by Ryland's unfortunate death, in an unfinished state, has since been completed by Bartolozzi. This artist also engraved in lines, "Antiochus and Stratonice," from Pietro de Cortona, and "The first Interview between Edgar and Elfrida," from Angelica Kauffman, both large plates.

Ryland's engravings in the novel manner were, for the most part, printed in red, and this manner of engraving soon obtained the name of "the red chalk manner," and was run after with avidity by the public. With so much heedless anxiety was it pursued, that people never stopt to consider whether even red chalk or stumped drawings themselves, of which these prints were professed imitations, were so good representations of nature, or afforded a means so happy and efficient of transfusing the soul of painting, as the art which previously existed, of engraving in lines, and which was then exercised in high perfection by Bartolozzi, Strange, Vivares, and Woollet: it was enough that it was new and red; Ryland and novelty led the way, and fashion and the print-sellers followed.

The print-dealers, upon mistaken notions of private advantage, are ever exhaulting the permanent hopes of the art. Like savages, who are reckless of the future, they cut down the tree in order to obtain its fruit. The novelty of chalk engraving, by calling forth their ignorant exertions, coincided with, and encreased, the mania of the public, and except for the landscapes of Vivares, Rooker, and Woollet, which required and exhibited more vigour and more detail of drawing than stippling could bestow; and that now and then an historical engraving by Strange and Bartolozzi, and the series from West's history of England, (of which the death of general Wolfe was the first,) attested the existence and maintained the dignity of the legitimate art, the engravers of Great Britain were compelled to feel, and silently to acknowledge, that

" Since

## ENGRAVING.

“Since ignorance was bliss,  
’Twas folly to be wise.”

This mode of engraving, however, has since been greatly improved, and this improvement has been effected chiefly by living professors. For an account of its process and susceptibilities, see the article *STIPPLING*.

ENGRAVING, a mode or species of sculpture performed by incision. The radix of the word should rather be sought in the Hebrew, than in the Greek language, because the art itself was practised by the Hebrews and their Chaldean ancestors for centuries before Greece had existence.

There are several words used by the sacred historian to express or denote the work of the engraver. In the 25th chapter of Exodus, verse 9, פתח פתח signifies to make an opening, or incision; and hence come both the noun and its plural, פתוחים engravings.

One of the original senses of the root is *to plough up*, so that the engraver is called *the plougher*; and frequently the word אבן, *a stone*, is added for the sake of distinction, and both together may be properly translated *the plougher or engraver in stone*.

Mr. Strutt with much truth observes, that “no word can express more perfectly the operation of the engraver on metals of the present day (when performed simply with the graver) than the verb *to plough*.” His line is a furrow, and in cutting it he turns up the copper, or other metal, as the husbandman turns up the earth. The metal so turned up is termed the *burr*, which is afterwards removed with a tool termed by engravers a *scraper*.

In the 6th chapter of the first book of Kings, the word קלוי is used to express the hollowing out of the carved work upon the cherubim, palm trees, and open flowering in the sanctuary, which were afterwards filled up with gold; which word in the Latin Vulgate is rendered *sculpsit*; by others *calavit*; and by others *incidit*.

Engraving has been performed in different countries and at different periods of time, on various substances; chiefly on metals, wood, and the oriental precious stones, which are called gems, but with instruments that have varied but little since they were first invented. For the latter arts, see *GEM ENGRAVING* and *WOOD ENGRAVING*.

The metals upon which engraving is chiefly employed are copper and steel, the former for producing impressions on paper in various ways; the latter for striking coins, medals, &c.

Engraving on copper, for the purpose of producing impressions, may be divided into five species, engraving in aqua-tinta, for which see *AQUA-TINTA*; engraving in the chalk manner, for which see *STIPPLING*; engraving with aqua-fortis, for which see *ETCHING*; engraving on mezzotinto, for which see *MEZZOTINTO ENGRAVING*, and the original art of engraving *in lines*.

Engraving in lines, for the purpose of producing impressions on paper, may almost be said to be an art of modern invention, for though the ancients ornamented their pateras, armour, metal vases, &c. by this means, they appear never to have thought of printing from the incisions, or lines cut with the graver; nor was it thought of at all until about the middle of the 15th century, for which see our accounts of the *GERMAN* and *ITALIAN Schools of Engraving*.

This art is chiefly employed in representing historical subjects, landscapes, portraits, &c. &c. after pictures, or other designs made for the purpose.

It is performed, as we have stated, with the graver, dry point, or more frequently with the work of both these

tools, mingled with lines corroded with aqua fortis. For the first there need but little apparatus, and few instruments. The plate you work on being well polished, (for the method of preparing which, see *COPPER-PLATES*;) is covered over with a thin skin of virgin-wax, and on this the outline of the draught, or design, done in black lead, red chalk, or other ungummed matter, is laid; and rubbed down for the wax to take off. The design, thus transferred upon the wax, is traced through on the copper, with a point, or needle; then heating the plate, and taking off the wax, the strokes remain; to be followed, heightened, &c. according to the tenor of the design, with the graver, which is to be very sharp, and well tempered.

The dry point, or needle, which has been of late much used in engraving, is a tool like an etching point, which being drawn hard on the copper, cuts a stroke, and raises a burr; the burr is scraped off, and there remains a stroke more soft and delicate than can be produced in any other way. See *DRY POINT*.

In the adroit conduct of the graver and dry point the art chiefly consists; for which there are no rules to be given; all depending on the habitude, disposition, and genius, of the artist. However, some general observations and directions may not be improper. As the principles of engraving are the same with those of painting, a person cannot expect to attain any considerable degree of perfection in this art who is not a good master of design; and therefore he ought to be well acquainted both with perspective and architecture: for the former, by the proper degradations of strong and faint tints, will enable him to throw backward, or bring forward, the figures and other objects of the picture or design which he proposes to imitate; and the latter will teach him to preserve the due proportion of its several orders, which the painter often entrusts to the discretion of the engraver. In order to preserve equality and union in his works, the engraver should always sketch out the principal objects of his piece before he undertakes to finish them. Care should be taken that the graver be carried level upon the plate, and be pressed, as occasion requires, with greater or less force, carrying the hand as evenly as possible. In engraving straight lines, a less degree of pressure serves for those that are finer, and a greater is required to form the broader and deeper lines. In forming circular or curved lines, the hand and graver must be held steady, and the plate is to be moved upon the cushion under the graver. In large works a cushion is useless. The engraved work may be rendered more visible, by rubbing it over with a roll of felt, dipt in oil, and which is called an oil rubber. The strokes of the graver should never be crossed too much in the lozenge manner, particularly in the representation of flesh, because sharp angles produce the unpleasing effect of lattice-work, and take from the eye the repose which is agreeable to it in all kinds of picturesque designs: we should except the case of clouds, tempests, waves of the sea, the skins of hairy animals, or the leaves of trees, where this method of crossing may be admitted. But in avoiding the lozenge, it is not proper to get entirely into the square, which would give too much of the hardness of stone. In conducting the strokes, the action of the figures, and of all their parts, should be considered; and it should be observed how they advance towards, or recede from, the eye; and the graver should be guided according to the risings or cavities of the muscles or folds, making the strokes wider and fainter in the light, and closer and firmer in the shades. Thus the figures will not appear jagged; and the hand should be lightened in  
such

such a manner, that the outlines may be formed and terminated without being cut too hard: however, though the strokes break off where the muscle begins, yet they ought always to have a certain connection with each other, so that the first stroke may often serve by its return to make the second, which will shew the freedom of the engraver.

In engraving the flesh, the effect may be produced in the lighter parts, and middle tints, by long pecks of the gravers, rather than by light lines; or by round dots, or by dots a little lengthened by the graver, or, best of all, by a judicious mixture of these together.

In engraving the hair and the beard, the engraver should begin his work by laying the principal grounds, and sketching the chief shades in a careless manner, or with a few strokes; and he may finish it at leisure with finer and thinner strokes to the extremities. When architecture is to be represented, except it be old and ruinous buildings, the work ought not to be made very black; because, as edifices are commonly constructed either of stone or white marble, the colour, being reflected on all sides, does not produce dark shades, as in other substances. Where sculpture is to be represented, white points must not be put in the pupils of the eyes of figures, as in engravings after paintings; nor must the hair or beard be represented as in nature, which makes the locks appear flowing in the air; because in sculpture there can be no such appearances.

In engraving cloths of different kinds, linen should be done with finer and closer lines than other sorts, and be executed with single strokes. Woollen cloth should be engraved wide, in proportion to the coarseness or fineness of the stuff; and when the strokes are crossed, the second should be smaller than the first, and the third than the second. Shining stuffs, which are generally of silk or satin, and which produce flat and broken folds, should be engraved more hard and more straight than others, with one or two strokes, as their colours are bright or otherwise; and between the first course of lines other smaller must be occasionally introduced, which is called interlining. Velvet and plush are expressed in the same manner, and should always be interlined. Metals, as armour, &c. are also represented by interlining, or by clear single strokes. In architecture, the strokes which form the rounding objects should tend to the point of sight; and when whole columns occur, it is proper to produce the effect as much as possible, by perpendicular strokes. If a cross stroke is put, it should be at right angles, and wider and thinner than the first stroke. The strokes ought to be frequently discontinued and broken, for sharp and craggy objects. Objects that are distant towards the horizon should be kept very tender. Waters that are calm and still are best represented by strokes that are straight, and parallel to the horizon, interlined with those that are finer; omitting such places as, in consequence of gleams of light, exhibit the shining appearance of water; and the forms of objects, reflected from the water at a small distance upon it, or on the banks of the water, are expressed by the same strokes, retouched more strongly, or faintly, as occasion may require, and even by some that are perpendicular. For agitated waters, as the waves of the sea, the first strokes should follow the figure of the waves, and may be interlined, and the cross strokes ought to be very lozenge. In cascades, the strokes should follow the fall, and be interlined. In engraving clouds, the graver should sport, where they appear thick and agitated, in turning every way according to their form, and their agitation. If the clouds are dark, so that two strokes are necessary, they should be

crossed more lozenge than the figures, and the second strokes should be rather wider than the first. The flat clouds, that are lost insensibly in the clear sky, should be made by strokes parallel to the horizon, and a little waving; if second strokes are required, they should be more or less lozenge; and when they are brought to the extremity, the hand should be so lightened, that they may form no outline. The flat and clear sky is represented by parallel and straight strokes, without the least turning. In landscapes, the trees, rocks, earth, and herbage, should be etched as much as possible: nothing should be left for the graver but perfecting, softening, and strengthening. The dry point produces an effect more delicate than the graver can, and may be used to great advantage in linen, skies, distances, ice, and often in water, especially in small engravings. In most things it is proper to etch the shadows, only leaving the lighter tints for the dry point, graver, &c.

The other instruments, besides the graver and dry point, are, a cushion, or sand-bag, to lay the plate on, to give it the necessary turns and motions: a burnisher, round at one end, and usually flattish at the other, to rub out slips and failures, and to soften the strokes, &c. A scraper, to pare off the surface, on occasion, and remove the burr; and a rubber of black cloth, or hat, to fill up the strokes, that it may shew how the work proceeds: but the latter should be sparingly used.

ENGRAVING on steel, is chiefly employed in cutting punches, matrices, and dies, proper for striking coins, medals, and counters.

The method of engraving, with the instruments, &c. are the same for coins as for medals and counters: all the difference consists in their greater, or less relief; the relief of coins being much less considerable than that of medals; and that of counters still less than that of coins. The engraver in steel usually begins with punches, or punchions, which are in relief, and serve for making the creux, or cavities of the matrices, and dies; though sometimes he begins immediately with the creux; but it is only when the intended work is to be cut very shallow. The first thing is to design his figures; then he moulds them in white wax, of the size and depth required; and from this wax he graves his punch.

This punch is a piece of steel, or, at least, of iron and steel mixed; on which, before they temper, or harden it, the intended figure, whether a head, or a reverse, is cut, or carved, in relief. The instruments used in this *graving* in relief, which are much the same as those wherewith the finishing of the work in creux is effected, are of steel: the principal are, gravers of divers kinds, chisels, flatters, &c. when the punch is finished, they give it a very high temper, that it may the better bear the blows of the hammer, where-with it is struck, to give the impression to the matrice.

What they call *matrice*, or *matrix*, is a piece of good steel, of a cubic form, called also the *dye*, whereon the relief of the punch is struck in creux: it is called *matrice*, because in the cavities, or indentures, thereof, the coins, or medals, seem formed, or generated, as animals are in the matrix of their mother. To soften this steel, that it may more easily take the impressions of the punch, they make it red-hot; and, after striking the punch thereon in this state, they proceed to touch up, or finish, the strokes and lines, where, because of their fineness, or the too great relief, they are in any respect defective, with some of the tools above-mentioned.

The figure thus finished, they proceed to engrave the rest

of the medal; as the mouldings of the border, the engraved ring, letters, &c. all which, particularly the letters, and graving, or engraving, are performed with little steel punches, well tempered and very sharp. Add, that as they sometimes make use of puncheons to engrave the creux of the matrix, so, on some occasions, they make use of the creux of the matrix to engrave the relievo of the punch.

To see and judge of the engraving in creux, divers means have been devised to take the impressions therefrom, as the work proceeds; sometimes they make use of a composition of common wax, turpentine, and lamp-black; which, always retaining its softness, easily takes the impression of the part of the graving it is applied to; but this only serving to shew the work piece-meal, they have had recourse to other ways to shew the whole figure. The first by pouring melted lead on a piece of paper, and clapping the matrice thereon; the second, with melted sulphur, managed the same way; and the third, proper only where the graving is shallow, by laying a piece of soft paper on the graving, and over the paper a leaf of lead; when giving two or three blows with a hammer on the lead, the paper takes the impression of the work.

When the matrix is quite finished, they temper it, rub it well with a pumice-stone, and clean out the stone again with a hair-brush; and, lastly, polish it with oil and emery: in this condition it is fit for the mill, to be used to strike coins, medals, &c.

After the like manner are the matrices for casting of printing letters engraven. See *Letter Foundery*.

*ENGRAVING of seals, stamps, puncheons, marking irons, gilding irons,* and other matters, for goldsmiths, pewterers, bookbinders, &c. either in relievo, or indenture, is performed after the manner last described.

*ENGRAVING in wood.* See *CUTTING in wood,* and *Wood Engraving*.

*ENGRAULIS,* in *Ichthyology*, a name given, by some authors, to the anchovy, called also, by some, lycostomus, and, by others, halecula. See *ENCRASICOLUS*.

*ENGROSSING,* the writing a deed over fair and in proper legible characters. Among lawyers it more particularly means the copying of any writing fair upon parchment, or stamped paper. See *COPY, CALLIGRAPHUS, &c.*

*ENGROSSING,* in *Law*, denotes the getting into one's possession, or buying up large quantities of corn, or other dead victuals, with intent to sell them again. This must of course be injurious to the public, by putting it in the power of one or two rich men to raise the price of provisions at their own discretion. And so the total engrossing of any other commodity, with intent to sell it at an unreasonable price, is an offence indictable and fineable at the common law. (Cro. Car. 232.) And the general penalty for this offence, as well as for *forestalling* and *regrating* (which see), by the common law, (for all the statutes concerning them were repealed by 12 Geo. III. c. 71.) is, as in other minute misdemeanors, discretionary fine and imprisonment. (1 Hawk. P. C. 235.) Among the Romans these offences, and other mal-practices to raise the price of provisions, were punished by a pecuniary mulct. "Pœna viginti aureorum statuitur adversus eum, qui contra annonam fecerit, societatemve coierit quo annona carior fiat." (Inf. 48. 22. 2.)

*ENGSTLEN,* in *Geography*, a remarkable spring of Switzerland, in the canton of Berne, in the valley called Gentel. The water flows only from the beginning of May till the latter end of August, and that twice a day to-

wards eight o'clock in the morning, and towards four in the afternoon. This circumstance is considered as miraculous: the inhabitants fancy that providence purposely sends them this water in the season, and at the time when they are to water their cattle. Nothing, however, is more easily explained than this phenomenon. Many brooks issue from mount Engstlen, and form a small lake. In the summer months, the snow water causes this lake to overflow; and the melting of the snow begins with the day, and ceases towards night. F. I. Durand's *Statistique élémentaire de la Suisse*, 1795.

*ENGUELEGUINGIT*, a town of Africa, in the empire of Morocco, not far from Mogador.

*ENGUICHE*, in *Heraldry*, is applied to the great mouth of a hunting horn, when it has a rim of a different colour from the horn itself.

*ENGYSCOPE*, from *εἶς*, near, and *σκοπεω*, I observe, a machine better known under the name of microscope. See *MICROSCOPE*.

*ENGYTHECA*, from *εἶς*, near, and *θησαυρον*, repository, in *Antiquity*, a cup-board, or place where cups and other vessels used to be laid.

*ENGYUM, or ENGUYUM,* in *Ancient Geography*, a town of Sicily, situated near mount Maurus, at the springs of Alæsus. Cicero (in Verr.) represents it as one of the most considerable cities of that island. It was founded by the Cretans, and famous for a temple dedicated to Ceres, in which, it was constantly affirmed, certain goddesses, called the "Mothers," appeared from time to time. Plutarch says, that this temple was built by the Cretans, and dedicated to these goddesses so called, viz. Cybele, Juno, and Vesta. This writer adds, that in the temple were lodged javelins and brazen helmets, which had been consecrated to the goddesses of the place by Meriones and Ulysses. The town was situated in the interior of the island, to the west of Hubita.

*ENHADDAD*, a town of Judea, comprised in a part of the tribe of Issachar.

*ENHALLOW*, in *Geography*, one of the smaller Orkney islands, between Rowfa and Pomona.

*ENHANCE, To,* in *Law*, is to raise the price of goods or merchandize. See *ENGROSSING* and *FORESTALLING*.

*ENHANCED*, in *Heraldry*, a term applied to any ordinary, when removed from its usual situation, and placed higher in the field.

*ENHARMONIC GENUS*, in the *Ancient Greek Music*. The Greeks included all musical sounds in three genera or kinds of interval: the diatonic, for tones and semi-tones; the chromatic, for semi-tones and minor thirds; the enharmonic, for quarter-tones and major thirds. The scale of each genus was arranged in tetrachords, or systems of four sounds, of which the first and last were stantes, immobiles, or fixed; while the two middle sounds were termed mobiles, or changeable: and it is by these changes that the genera are distinguished.

Each of the three genera had some sounds in its scale that were peculiar and characteristic, and some that were in common with the other two. For instance, B C E F A Bb and d, were used in all the three genera, whereas D G were peculiar to the diatonic, Cx and Fx to the chromatic, and Bx Ex and Ax to the enharmonic. A complete scale of each genus in modern notes will explain this matter better than words.

The image shows three musical staves, each with a treble clef and a key signature of one flat (B-flat). The staves are labeled 'Diaton.', 'Chrom.', and 'Enhar.' on the left. Above each staff, five tetrads are indicated by brackets and labeled '1st Tetr.', '2d Tetr.', '3d Tetr.', '4th Tetr.', and '5th Tetr.'. The notes in each tetrad are as follows:

- Diaton.:** 1st: C, D, E, F; 2nd: G, A, B, C; 3rd: D, E, F, G; 4th: A, B, C, D; 5th: E, F, G, A.
- Chrom.:** 1st: C, D, E, F; 2nd: G, A, B, C; 3rd: D, E, F, G; 4th: A, B, C, D; 5th: E, F, G, A.
- Enhar.:** 1st: C, D, E, F; 2nd: G, A, B, C; 3rd: D, E, F, G; 4th: A, B, C, D; 5th: E, F, G, A.

This subject will be further pursued under the articles *Ancient Greek Music*, *GENERA*, and *TETRACHORDS*.

As modern melody is built upon harmony, derived from the harmonics of a fundamental-base, we have no instruments with quarter-tones, or which can furnish a base to an enharmonic melody, if we had the power of framing and executing it with the voice or violin. We have, therefore, only two genera in our music, with all our refinements in melody of nominal enharmonic sharps, dieses, double flats, and sharps, &c.: which two genera, the diatonic, consisting of five tones and two semi-tones in the octave, such as the key of C natural supplies upon keyed instruments; and the chromatic, consisting entirely of semi-tones, twelve in number, such as moving from any given note to its octave by semi-tones will furnish. See *TONE*, *SEMI-TONE*, and *Enharmonic SHARPS* or *DIESES*.

*ENHARMONIC Diesis*, is an interval whose ratio is  $\frac{125}{128} = 21\Sigma + 2m$ . See *Enharmonic DIESES*.

*ENHARMONIC Degree of Aristoxenus*, otherwise his diesis quadrantal, was a quarter of the major tone, or  $26\Sigma + \frac{1}{2}f + 2\frac{1}{2}m$ .

*ENHARMONIC Degree of Euclid*, otherwise his diesis quadrantal, was three-thirtieths of a minor fourth, or  $25\frac{2}{3}\Sigma + \frac{1}{2}f + 2\frac{1}{2}m$ .

*ENHARMONIC Ditone of Euclid*, was twenty-four thirtieths of a minor fourth, or  $203\frac{1}{3}\Sigma + 4f + 17\frac{2}{3}m$ .

*ENHARMONIC Quarter of a tone*, is the same with *enharmonic diesis*, above.

*ENHYDRI*, in *Chemistry*, are small nodules of chalcidony, each containing a drop of water, which are found in the porous trap of the picentine. They are often polished and set in rings, rather as an object of curiosity than of much beauty; and after a time the water usually disappears by evaporation.

*ENHYDRIA*, in *Ancient Geography*, a town of Phœnicia, between Caranus and Marathus. Strabo.

*ENHYDRIS*, the ancient Greek name for the otter.

*ENJEDIM, GEORGE*, in *Biography*, a learned Unitarian divine, who flourished in the 16th century, was a native of Hungary, whence he removed to Transylvania, where he became a superintendant of the Unitarian churches. He died in the year 1597, and was regarded as one of the best writers in what is called the Socinian cause. His principal work was entitled "Explicatio Locorum Scripturæ

Veteris et Novi Testamenti, ex quibus Dogma Trinitatis stabiliri solet," 4to. The first impression of this work was burnt by the orthodox, but a new edition was afterwards published in the Netherlands. Moreri.

*ENIF*, in *Astronomy*, a fixed star of the third magnitude, in Pegasus's mouth.

*ENIGMA*. See *ÆNIGMA*.

*ENIMIE, SAINTE*, in *Geography*, a small town of France, in the department of Lozere, 12 miles S.W. of Mende, in a country formerly known by the name of le Gévaudan.

*ENINGIA*, in *Ancient Geography*, a country or island in the north of Europe, in the Serius Codanus or Baltic sea, according to Pliny; supposed by some to be Finland.

*ENIPEUS*, or *ENIPE*, a river of Greece, in Triphylia, which ran W. of Heraclea. In the time of Strabo, it was called *Barnichius*.

*ENIPPA*, or *AGONIPPA*, a mountain of Greece, in Bœotia.

*ENISEI* and *ENISEISK*. See *YENISEI* and *YENISEISK*.

*ENISIPIA*, an island of the Mediterranean sea, near Egypt, called *Ænesippa* by Ptolemy, and *Enesipasta* by Strabo.

*ENISPA*, a town of the Peloponnesus, in Arcadia, called *Enispa* by Seneca the tragedian.

*ENIX*, in *Geography*, a town of Spain, in the province of Grenada; 8 miles W. of Almeria.

*ENIXUM SAL*, in *Chemistry*, is the sulphat of potash remaining after the preparation of nitrous acid. It is pure, if only nitre and sulphuric acid have been made use of: but as the manufacturers of aquafortis usually employ green vitriol instead of sulphuric acid, the residual salt is much mixed with colcothar or oxyd of iron; from which, however, it may be separated by subsequent solution and crystallization.

*ENKIANTHUS*, in *Botany*, from *εγκυος*, pregnant, and *ανθος*, a flower, "because," says Loureiro, "its flowers are pregnant with others." Loureir. Cochinch. 276. Clais and order, *Decandria Monogynia*. Nat. Ord. —.

Gen. Ch. *Common Cal.* of six roundish, concave, pointed, coloured leaves. *Common Cor.* of eight oblong, flat, spreading petals, containing five florets, on long reflexed stalks.

*Perianth* of five small, permanent, acute, coloured leaves. *Cor. proper* of one petal, bell-shaped; tube wide; limb short, in five rounded segments. *Stam.* Filaments ten, awl-shaped, tumid at the base, hairy, attached to the bottom of the corolla, and shorter than its limb; anthers ovate, incumbent. *Pist.* Germen five-sided, superior; style thick, as long as the stamens; stigma simple, coloured, shining. *Peric.* Berry ovate-oblong, five-sided, of five cells. *Seeds* numerous, oblong, small. *Loureiro.*

Eff. Ch. Common Calyx to several flowers; proper one inferior, of five leaves. Corolla bell-shaped, five-cleft. Berry of five cells, with many seeds.

The species are two.

1. *E. quinqueflora.* "Calyx containing five flowers. Stem arboreous." Tsiu tsung hōa of the Chinese. Cultivated at Canton. Its branches laden with red flowers, before the leaves expand, are kept for several days in china vases of water among the opulent Chinese, and are very ornamental, though destitute of scent. The tree is of a middle size, with a smooth bark, and spreading branches. Leaves crowded, oblong, pointed, entire, smooth. Flower solitary, of a beautiful red, crowned with a white fringe, and containing five florets within.

2. *E. biflora.* "Calyx containing two flowers. Stem shrubby." Sāu liēo hōa of the Chinese. Native of Canton. A shrub three feet high, with spreading branches. Leaves lanceolate-ovate, entire, hairy, small, crowded, with short footstalks. Flowers scarlet, terminal, crowded, sessile. Common Calyx of five coloured, ovate, concave, deciduous leaves. Common Corolla none. Florets two in each common calyx. *Perianth* small, deeply five-cleft; its segments lanceolate, hairy, spreading. *Cor.* bell-shaped, spreading; tube with five furrows or plaits; limb in five deep, ovate, large segments. *Filaments* ten, thread-shaped, erect, unequal, rather shorter than the corolla, inserted into the receptacle; anthers ovate, incumbent. *Germen* ovate, very hairy; style thread-shaped, longer than the corolla; stigma thickish, five-cleft, gaping. *Berry?* (not seen ripe), ovate, with five cells and many very small roundish seeds.

The above is Loureiro's account of the genus in question, concerning which we confess ourselves unable to form any decided opinion. His description of the second species is a little at variance with the generic characters, and what he every where terms a common calyx and common corolla must of course be bracteas. Some particulars indicate a plant of the *Arbutus* or *Vaccinium* tribe, but others disagree. Ornamental scarlet flowers, so well known at Canton, must long ago have been introduced to the acquaintance of European botanists. This is one of those botanical enigmas with which the good father Loureiro's book abounds, in consequence of his having studied almost entirely without communication with other botanists. Hence he took the *Hydrangea* for a *Primula*, and made a new genus of *Argemone mexicana*. See *ECHTRUS*.

ENKIOPING, or ENDKIOPING, in *Geography*, a small town of Sweden, situated on a river close to an inlet of the lake Mæler, and consisting chiefly of wooden houses painted red. It stands on a ridge of ground composed of sand and gravel, which once formed the shore of the lake; 21 miles S.W. of Upsal.

ENKIRCH, a town of Germany, in the circle of the Upper Rhine, and county of Sponheim; 3 miles N. of Traarbach.

ENKUSEN, a town of the island of Borneo.

ENLARGE, in the *Manege*, is used for making a horse go large, that is, making him embrace more ground than he before covered. This is done when a horse works upon

a round, or upon volts, and approaches too near the centre, so that it is desired he should gain more ground, or take a greater compass. To enlarge your horse, you should prick him with both heels, or aid him with the calves of your legs, and bear your hand outwards. If your horse narrows, he is enlarged with pricking him with the inner heel, and sustaining him with the outer leg, in order to press him forwards, and make his shoulders go. Upon such occasions the riding-masters cry only large, large. See *IN*.

ENLARGER L'ESTATE, in *Law*. See *RELEASE*.

ENLARGING STATUTE. See *STATUTE*.

ENMANCHE', in *Heraldry*, is when a chief has two lines drawn from the middle of the upper edge, to the sides, the depth of half the chief; the two lines including an obtuse angle, whose vertex is the centre of the top of the chief.

The heralds conceive this, as bearing some resemblance to sleeves; whence the etymology of the word, from the French *manche*, sleeve. It differs from *chappe*, where the lines come from the top to the bottom of the chief.

ENNA, in *Ancient Geography*, now *Castro Giovani*, a city of Sicily, situated on an eminence in the middle of the island, whence, according to Diodorus, it was called the "navel of Sicily." It was one of the strongest places in the island, and remarkable for its beautiful plains, fruitful soil, and the numerous lakes and springs which watered its territory; and the waters of which were highly commended for their limpidity and salubrity. Diodorus informs us, that Ceres was born in this district; and that she first taught the inhabitants of Enna the art of agriculture. He adds, that the rape of Proserpine by Pluto happened near Enna, while the young goddess was gathering flowers in a neighbouring meadow. The Enneans shewed a large cavern, which, as they believed, opened of itself, to make the god a way to his infernal kingdom. Hence originated the worship which the Sicilians paid to these two divinities; the magnificent temple which Gelo erected to Ceres in this city; and the solemn festival, which the Syracusians annually celebrated near the fountain Cyane, supposed to have sprung up when the earth opened under Pluto's feet. The temple of Ceres was famous and resorted to from all parts of Italy, Greece, and Asia, and was deemed one of the richest in Italy.

ENNEACHORD, in *Ancient Music*, an instrument with nine strings.

ENNEACRUNOS, q. d. the nine fountains, in *Ancient Geography*, a fountain of Greece- in Attica, at the foot of mount Hymettus, the waters of which were conveyed through nine pipes or channels into the town, constructed by order of Pisistratus.

ENNEACTIS, in *Natural History*, a name given by Linkius to a sort of star-fish, of the more branched or astrophyte kind, which has only nine rays, where they first part from the body, but these divide into a vast number of others afterwards.

ENNEADECATERIS, in *Chronology*, a cycle, or period, of nineteen solar years.

The word is formed of *ennea*, nine; *deka*, ten; and *eros*, year.

Such is the lunar cycle invented by Meton, at the end whereof the moon returns nearly to the same point from which it departed. Whence the Jews, Athenians, and other nations, who were disposed to accommodate the lunar months to the solar years, made use of the enneadecateris; allowing to the year of the years thirteen months apiece, and to the rest twelve. See *CYCLE*, and *EMBOLISMIC*.

ENNEADECATERIS, the Jewish, is properly a cycle of 19 lunar

lunar years, beginning from *molad tohu*, and returning again and again; whereof every 3d, 6th, 8th, 11th, 14th, 17th, and 19th, are embolismic, or of 383 days 21 hours apiece; the rest common, or of 354 days 8 hours apiece. See YEAR.—Consequently, the Jewish enneadecateris is 6930 days 18 hours.

ENNEAGON, in *Geometry*, a figure of nine angles, and nine sides.

The word is formed of *εννεα*, nine; and *γωνια*, angle.

ENNEAGON, in *Fortification*, denotes a place with nine bastions. See FORTIFIED PLACE.

ENNEAHEDRIA, derived from the Greek *εννεα*, nine, and *ειδης*, a side, in *Natural History*, the name of a genus of spars.

The bodies of this genus are spars, composed of nine planes, in a trigonal column, terminated at each end by a trigonal pyramid. Of this genus there are four known species. Hill's *Hist. of Foss.* p. 208.

ENNEANDRIA, in *Botany*, from *εννεα*, nine, and *ανδρ*, a man, the ninth class of the sexual or artificial system of Linnæus, consisting of plants with nine separate or distinct stamens in the same flower with the pistil or pistils. It contains three orders, *Monogynia*, of which the valuable genus *Laurus*, including the Cinnamon, Cassia, one sort of Camphor, Sweet Bay, &c. is an example, and there are some other fine plants in this order; *Trigynia*, of which *Rheum* or Rhubarb, nearly allied to *Rumex*, is the only instance, and *Hexagynia*, consisting of *Butumus umbellatus* alone. Hence it appears that nine is an unusual number in the parts of flowers, though not quite so uncommon as seven.

ENNEAPYRGÆ, in *Ancient Geography*, a town of Greece, in Attica, 7 or 8 leagues from the promontory of Sunium.

ENNEATICAL DAYS are every ninth day of a sickness; which, some imagine, naturally occasion a great alteration, either for the better or worse.

ENNEATICAL Years are every ninth year of a man's life. See CLIMACTERIC.

ENNEBACKA, in *Geography*, a town of Norway; 26 miles S.E. of Christiania.

ENNEEMIMERIS is one kind of the cæsura of a Latin verse, where, after the fourth foot, there is an odd syllable ending a word, which helps to make the next foot with the following word; as in this instance,

“ Ille latus niveum molli fultus hyacintho,”

where all the four kinds of the cæsura occur.

ENNEL LOUGH, in *Geography*, a lake of the county of Westmeath, Ireland, near Mullengar.

ENNEOPHTHALMOS, from *εννεα*, nine, and *οφθαλμος*, eye, in *Zoology*, a name given by some to the lampræy.

ENNERIS, in the *Ancient Ship-Building*, a name given to those galleys, or vessels, which had nine tiers of rowers. These were of a very considerable size; though Meibom has found for convenient a method of placing the rowers that he has taken off very much from that immense height others supposed they had above the water. We read of the tessaracontes, and other amazing vessels of this fabric; and that of Philopater having forty rows of oars, and that of Ptolemy Philadelphus, thirty; and some others which are spoken of, twenty. It has been disputed by many, whether such large vessels as these were ever actually built, or used; but Meibom gives great reason to believe that they really were, though he, at the same time, alleges against Salmasius, and the more sanguine admirers of the works of the ancients, that very few vessels were built larger than these

enneres, or nine tiered ones, and proves it from Livy and Plutarch, and from Polybius. We are apt to admire, in many cases, what we ought also to imitate, but never attempt it. This is the case in these galleys; and Meibom, who has given the rules of this ancient naval architecture, is of opinion, that by imitating it at present, modern galleys and galleasses might be built much more conveniently both for strength and celerity, and also at less expence, than they are at present. Meibom. de Trirem.

The modern form is indeed allowed to be better than theirs; but if in the structure, the proportion of the long ships of the ancients were observed, they might be greatly improved: in the modern way of five men sitting at one oar in the galleasses, much strength is wasted to no purpose, because they sit too near to the fulcrum, or stay, whereas a smaller number of rowers, at a greater distance from the stay, would give more strength, and throw the vessel along much more swiftly, and would require less charge. Galleys of this sort, thus managed at a small expence, would be found of great use in the large rivers, and in the shallow seas, and therefore convenient for the Baltic, the Britannic, and the Mediterranean seas, and would be the most useful of all vessels for transporting great numbers of forces.

ENNEZAT, in *Geography*, a small town of France, in the department of the Puy de Dôme, chief place of a canton in the district of Riom, with a population of 2393 individuals. The canton contains 8 communes and 9168 inhabitants, on a territorial extent of 142½ kilometres.

ENNIS, a post-town in the county of Clare, Ireland, of which it is the capital. It is large and populous, and has the advantage of a small port at Clare, which is situated a few miles lower on the river Fergus; the tide bringing up large boats thence to Ennis. There are at this town the remains of one of the finest abbey-churches in Ireland, built in an elegant style of Gothic architecture. It is a borough town, and sends one member to the united parliament. It is 112½ Irish miles S.W. by W. from Dublin, and 17 N. by W. from Limerick. W. long. 8° 54'. N. lat. 52° 49'.

ENNISCORTHY, a post-town of the county of Wexford, Ireland. It is situated on the river Slaney, which is navigable for small sloops to this town. Its situation is agreeable and picturesque; and there are the remains of a considerable castle built by the first English settlers. It is the estate of the earl of Portsmouth. Enniscorthy has a manufacture of coarse woollen-cloth, and is a thriving town. Near it are lead mines, which are very productive. Vinegar-hill, near this town, was a strong hold of the insurgents in 1798; and the loyal inhabitants were great sufferers at that eventful period. Enniscorthy was represented in parliament before the union. It is 60 miles S. from Dublin, and near 12 N. from Wexford.

ENNISKILLEN, a post-town of the county of Fermangh, Ireland, and the place where the assizes are held. It is built in an island, formed by the river which unites the two lakes, and is the single pass of communication between the parts of the county which these waters separate. The strength of its situation pointed it out as a military post; and when the adherents of James II. excited a just alarm throughout the country, numbers flocked to this place, where they bravely resisted a much superior force, and even gained several important victories. These valiant men were formed into a regiment, which rendered effectual service to king William; and to this day the 27th regiment glories in the name of the *Enniskillers*. There is a school here, founded by James I. on the plantation of Ulster, the income of which, by the great rise in the value of lands, has become very considerable. Enniskillen returns one member

to the imperial parliament. Distance from Dublin N.W. 79 miles.

**ENNISTYMOND**, or **INNISTYMOND**, a small post-town of the county of Clare, Ireland; situated 118 miles W. by S. from Dublin, and 13 W. from Ennis.

**ENNIUS**, **QUINTUS**, in *Biography*, an ancient poet, was born at Rudia, a city of Calabria, near Tarentum, about the year of Rome 514, B. C. 237, and flourished about the close of the first Punic war. According to Silius Italicus, he served as a centurion in Sardinia, when that island was subdued by T. Manlius, and distinguished himself by his valour. After the war he probably remained in Sardinia; for Cornelius Nepos informs us, that Cato, the censor, when prætor, brought back with him from his government of Sardinia, the poet Ennius, who must at this time have been in his 35th year. Another of his patrons was Scipio Africanus the elder, who made him his companion in most of his campaigns. This fact we learn from Claudian. He was also intimate with Scipio Nafica. The notice taken of him by these eminent persons affords favourable testimony to his general character and manners; although Horacé (Epist. xix. l. 1.) represents him as warming his heroic vein by liberal potations. The gout, with which he was afflicted, and his depressed circumstances, were probably owing to his intemperance. These evils, however, he bore with great equanimity; and his life was prolonged to the age of 70. He is said to have been the father of epic or heroic poetry among the Latins, though the Greek was his mother-tongue. He was distinguished by that rustic vigour, which is the usual characteristic of genius in an unpolished age. Thus Ovid represents him;

“Ennius ingenio maximus, arte rudis.”

Lucretius mentions his having first brought the muse to Latium; and Virgil has transferred into his works many whole or half lines from Ennius, thus testifying his esteem of him. The events of Roman history formed the leading subjects of a large performance entitled “Annals,” subsequently divided into eighteen books. On certain days he was accustomed to recite portions of this poem. He also composed tragedies, comedies, epigrams, and satires; and also some didactic works. By his life of Scipio Africanus, he engaged the affection of the Cornelian family, who manifested their gratitude to him even after his death, depositing his ashes in the same tomb with those of Scipio, and erecting a marble statue to him near that of this great commander. The poet Nævius, who was his contemporary, after having made some campaigns in the first Punic war, wrote the history of that war in verse, according to the taste of those times. Fragments only of the works of Ennius remain; these have been published separately, Amst. 4to. 1707, and also in Mattaire’s *Corpus Poetarum*.

**ENNODIUS**, **MAGNUS FELIX**, bishop of Pavia in the sixth century, was born of illustrious parents about the year 473. His education and maintenance devolved upon an aunt, by whose death, before he was sixteen years of age, he was reduced to distressing circumstances, but afterwards, by a fortunate marriage, he attained to a state of affluence. Notwithstanding this union, he had a strong inclination for the ecclesiastical profession, and obtained his wife’s consent to enter into holy orders, whilst she at the same time embraced a religious life. He was ordained a deacon by Epiphanius, bishop of Pavia, with whom he lived in habits of the strictest intimacy and friendship. He had an early taste for literature, which he cultivated in connection with his theological studies, with so much success as obtained for him the reputation of an ex-

cellent scholar. On the death of his friend Epiphanius, he was admitted among the deacons of the church of Rome, and for some services done for the popes and church, he was promoted to the see of Pavia about the year 510, and appointed on the commission for negotiating a re-union between the eastern and the western churches. The only reward for his services in this respect, was drawing down upon his head the resentment of the emperor Anastasius, who, after much ill treatment, dismissed him home in a shattered vessel, with a strict prohibition of never again landing at any port in Greece, by which his life was exposed to the most imminent danger. He arrived safe in Italy, but died as he was on his journey to Pavia, in the 48th year of his age. His works are numerous, and have been frequently printed; they were published, with many useful explanatory notes, at Paris, in the year 1611. Mofheim *Ecel. Hist.* Moreri.

**ENNUI**, a French term which is sometimes used to denote a kind of littlefness or unaptness for mental exertion; or which may be more scientifically defined to mean the uneasiness that prevails during the absence of mental impressions. The aversion from *ennui*, or the desire of intellectual emotion, is described by Helvetius, in his work “On Mind,” as a very powerful and general spring of conduct, and he ascribes to this law of the mind, perhaps, a greater degree of influence than that which properly belongs to it, conformably to the avowed sentiments of a writer, who maintains that “to judge is to feel,” (*juger c’est sentir.*)

**ENO**, in *Geography*, a town of European Turkey, in the province of Romania; the see of a Greek archbishop; 28 miles N.W. of Gallipoli.—Also, a river of America, in North Carolina, which unites with Little and Flat rivers in Orange county, and forms the Negus, about 17 miles below Hillsborough.

**ENOCH**, in *Biography*, the son of Jared and father of Methuselah, was the seventh in lineal descent from Adam, and born in the year B. C. 3382. Eminently distinguished by his piety and virtue in a corrupt age, he was translated to heaven in the 365th year of his age, without undergoing the pains of dissolution. An apocryphal book, entitled “The Book or Prophecies of Enoch,” has been ascribed to this celebrated antediluvian, and is cited, as some say, by Jude in his epistle, and more certainly by Irenæus, Clement of Alexandria, and other ancient fathers. But this book was probably forged in the second century. The Mahometans mention Enoch under the appellation of Edris, or Idris, and record many fables concerning him, which it is needless to mention.

**ENOCH**, in *Ancient Geography*, a city said to have been built by Cain in the land of Nod, where he and his family settled, and called after the name of his son Enoch. (Gen. iv. 16, 17.) Moses places it, according to our translation, on the east of Eden; and Ptolemy mentions a city called Anuchtha in Susiana, or Chusistan, a country lying eastward from Chaldæa, which the learned Huet supposes to have been the same with that built by Cain. But it seems very improbable, that the city of Enoch, built before the flood, should either withstand the deluge or retain its ancient name, after so great a change in the surface of the earth. Besides, Susiana being a very fertile and pleasant country, it is not likely that Cain should be banished thither, but rather to some barren and desolate land, remote from the place of his nativity, and separated by mountains, or other natural impediments, from intercourse with his relations. As there was another Enoch (see the preceding article) besides the son of Cain, it is not improbable that the city Anuchtha mentioned by Ptolemy, might have taken its name from him, whose memory would be held in veneration,

or from some other Enoch or Anoch, who might have lived after the flood. Grotius and Junius are of opinion, that the country into which Cain retired was the desert of Arabia; but as this country lies on the west, and not on the east of Eden, it is said, that the words which we translate "on the east" of Eden signify no more than "before" or "over-against" Eden, according to the translation of the Septuagint. According to this opinion; the land of Nod must have been Arabia Deserta, or some part of it, and not Sufiana. Wells's Geog. vol. i.

ENODIS, *CULMUS*, in *Botany*, a culm or straw destitute of any knot, joint, or prominent transverse interruption. See *CULMUS*.

ENOLA, in *Geography*, a town of Naples, in the province of Lavoura; 4 miles N. of Fundi.

ENOLMIS, *Ενολμις*, in *Antiquity*, a designation given to Apollo's priests at Delphi, because the fat on the tripod which was called olmos, *ολμος*. Hence also Apollo is called Enolmos, *Ενολμοις*. Pott. Archæol. Græc. lib. ii. cap. 9. tom. i. p. 275.

ENOMTEKIR, in *Geography*, a town of Swedish Lapland; 150 miles N. of Tornea.

ENON, in *Ancient Geography*, a place of Judea, situated near Jordan in the half-tribe of Manassch; which was the place in which John baptized, (John iii. 23.) because there was abundance of water. This place was between Shalim and Jordan, about 8 miles from Scythopolis.

ENOPA, a town of the Peloponnesus, in Messenia, situated on an eminence at a small distance N. of Cardamyla.

ENORAINE, in the *Manege*, a wither-wrung horse, or one that is spoiled in the withers. The word is obsolete.

ENORCHIS, in *Natural History*, the name given by many authors, to that species of ætites, or eagle-stone, in which the callimus, or internal nucleus, is not loose, so as to rattle in it when shaken, but remains fixed to one side. The Germans call this *hodenstein*. The outer crust is usually of a whitish colour, and the internal nucleus is yellowish or brownish, and it is usually of the size of a pigeon's egg, and of the shape of the human testicle; whence the name.

ENORMOUS, something excessive, or monstrous, especially in bulk. The colossus of Rhodes was of an enormous stature.

The word is formed of the privative *e*, and *norma*, rule; *q. d. void of, or contrary to, rule or measure; contra normam*. In the corrupt ages of Latinity, they used *innormis*, and *inormis*.

In the French jurisprudence, *leso enormis*, enormous damage, is that which exceeds half the value of the thing sold.

ENOTAEVSK, in *Geography*, a town of Russia, in the government of Caucasus, on the Volga; 72 miles N.N.E. of Astrachan.

ENOUREA, in *Botany*, (a barbarous name, from the Caribæan word *Enourou*.) Aublet Guian. v. 1. 587. t. 235. Juss. 249. The only species is *E. capreolata*, a climbing shrub, with something of the habit of a *Paullinia*, furnished with circularly-turned tendrils, pinnated leaves, spiked flowers, and a remarkable globular capsule of three valves, containing a globular seed imbedded in farinaceous pulp. Jussieu has copied its characters from Aublet, but Schreber has passed it by.

ENQUEST, or INQUEST, in *Law*, denotes an inquiry of a jury by hearing of witnesses.

This is the most usual manner of trial, in all causes, both civil and criminal, within this realm. In civil causes, after proof is made, on either side, of so much as each

party thinks good for himself; if the doubt be in the effect, it is referred to the discretion of twelve indifferent men, impanelled by the sheriff for that purpose; and as they bring in their verdict, so judgment passeth: for the judge saith, *the jury findeth the fact thus*. See WRIT of *Enquiry*. For the enquest in criminal causes, see JURY.

ENRICHED COLUMN. See COLUMN.

ENRICHING PLANTS, a term used, by the English farmers, to express such plants as are found to do good to land, rather than to exhaust it, and in consequence of which the same piece of land will produce a good crop of corn, though it would, without the assistance of their having been planted on it, have yielded a very poor one. The mystery of this difference between plants, some of which are found to burn up, that is, impoverish lands, while others enrich it, and leave it fitter for succeeding crops than they found it, is explained by Mr. Tull. This author having observed, that breaking the earth, by digging, or horse-hoeing, between the plants, gave them great increase, found that it was this practice that enriched the earth: and that, while corn and such plants as stand close, and cannot be hoed between, impoverish the ground, and suffer no means of enriching it again to be used, there were some other things, the crops of which being planted thinner, gave room to the earth to be ploughed, dug, or hoed between, and that these were the plants which were called the enriching kind by the farmers; and the whole secret lay in this, that the hoeing, ploughing, or otherways breaking the earth between them, in order to kill the weeds, enriched the ground greatly more, in proportion, than these plants exhausted it; and the consequence was, that though they had thriven very well, yet the earth was left richer than before, notwithstanding all that they had imbibed from it. Tull's Horsehoeing Husbandry, p. 37.

On this observation, this excellent author seems to have founded the system of what he calls horse-hoeing husbandry, concerning which he has written a large and useful treatise. He found that this stirring up of the earth enriched it so greatly, that, where it was used in a proper manner, the kind of plant need not be changed, but that the same earth would yield a successive series of crops of the same plant, and that even without dunging, or ever lying fallow, and every crop, for a long time, would be better than the former ones. The method of sowing, to this purpose, is not by scattering the corn with the hand, but sowing it in rows, and leaving large intervals between, the naked earth of which might be turned up by the hoe. See ALLEY and HOEING.

ENROL, in *Military Matters*, signifies the registering of such persons as, being enlisted, or appointed, are placed upon the rolls, or strength, of any particular regiment, troop, company, or portion of the military establishment. The act of enrolment seems to be held necessary in proof of a soldier's having become a servant of the state; equally so with the circumstance of his having received pay, or some money, however trifling, in advance. For it does not appear reasonable, that a soldier should be punished for absenting himself from that employ in which he has not received either pay, or subsistence. It is not, however, to be understood, that, after being duly enlisted in the presence of a magistrate, the recruit is at liberty to quit the party by whom he has been entertained: far otherwise; for though we hold a decided opinion regarding the devices often practised, to ensnare young men from their homes and families, we consider it indispensable that the sacred engagement should remain purely inviolate, after being once legally acknowledged.

knowledge by the party to be enrolled. See **INLIST** and **ENTERTAIN**.

In registering, that is to say in enrolling, a recruit, it is usual to be very exact in ascertaining the place of his nativity, his religion or sect, his age, his state of health, especially whether he be subject to fits, or be ruptured; while, for the purpose of apprehending him in case of desertion, his height, complexion, general figure, the colour of his hair, and of his eyes, together with any particular distinguishing marks, whether natural or accidental, are all noted; comprising, in the aggregate, what is called "description roll," of which a transcript is sent with each soldier, whenever draughted from one company or regiment to another.

Although a recruit is bound to the service after being examined and deemed competent to serve, by the inspecting surgeon, and the supervisor of the recruiting service of the district respectively, and after having acknowledged his being duly enlisted in presence of a magistrate, by whom the oath of allegiance should be tendered as conveniently might admit, he is not said to be enrolled until he is efficiently placed upon some list, whether under the recruiting officers, or in any particular regiment, troop, or company. In some instances, especially in the service of the East India Company, the whole of the recruits are lodged at a general depot, under the charge of officers fixed thereat, but without being attached to any particular regiments until their arrival in India: in the mean while they are formed into squads, under the immediate controul of non-commissioned officers, by whom they are trained in the rudiments of military discipline. We cannot with strict propriety say, that such men are enrolled; nor, indeed, do we hold the term to be applicable until they are in a certain degree fixed in some particular company, and entered upon its muster-roll, as well as upon the long-roll of the regiment.

**ENROLLMENT**. See **INROLLMENT**.

*Clerk of the ENROLLMENT of fines*. See **CLERK of the Inrollments**.

**ENS**, in Latin *Anisfa*, *Anasum*, or *Ensia*, in *Geography*, a town of Aultria, in the province called Upper Aultria, or the country above the Ens, in the district of Traun. It is situated on an eminence in the river Ens, which, not far from this place, falls into the Danube, 15 miles S. E. of Lintz, and 108 miles W. of Vienna. N. lat. 48° 11'. Its origin dates from the year 900, and it is built on the same spot where stood the Laureacum of the Romans, one of their colonies, which was destroyed by the Huns about the year 450. Ens is strongly fortified; its citadel is called *Enseck*, or the corner of Ens.

**ENS**, in Latin *Anisus*, or *Anasus*, a river of Germany, which has its source in the mountains of the former bishopric, now grand duchy of Salzburg, flows through Upper Aultria, and falls into the Danube near the town of Ens.

**ENS**, *Entity*, *Being*, in *Metaphysics*, is applied, in a general sense, to every thing which the mind any way apprehends, and whereof it affirms, denies, proves, or disproves, any thing. This other philosophers call cogitable, and intelligible; and the logicians, *thema*.

**ENS**, in a less general sense, signifies something that is, or exists, some way farther than by being conceived, or being capable of being conceived, in the mind. This is particularly called *ens positivum*, or *reale*; *positive*, or *real*, being. In opposition to which stands *non ens*.

**ENS**, in its proper, or restrained sense, is that to which there are real attributes belonging, or that which has a reality, not only out of the intellect, but in itself. This is what is properly meant by *res*, *thing*; and what we otherwise call *ens reale*, and also *substance*.

**ENS rationis**, is that which depends wholly on the mind, or which exists only in the imagination: of which they distinguish three kinds: *ens rationis affectivum*, which is done or produced by the mind, as knowledge; *ens rationis subiectivum*, which is received into the mind, as science; and *ens rationis objectivum*, which is represented by the mind, as a chimera, a golden mountain, or the like. Which last, if it have no other manner of being, i. e. if it be presented so as it does not, or cannot be, is what we most properly call *ens rationis*. The generality of school philosophers, and the Peripatetics among the rest, assert, that there are of these *entia rationis objectiva*. Others deny there are, or can be, any such things.

**ENS**, or **ENS primum**, in the *Ancient Chemistry*, denotes the most efficacious part of any natural mixed body, whether animal, vegetable, or fossile, wherein all the qualities or virtues of the ingredients of the mixed are comprehended in a small compass.

Paracelsus pretends to have been able to separate the *ens primum* from bodies, and with it to effect prodigious things towards the renovation and restoration of youth; but his processes are so obscurely delivered, that no body has been induced to try them.

**ENS primum salum**, a name given by Paracelsus to a preparation of sea salt, which he calls also a perpetual oil, and *sal circulatum*, which see.

**ENS martis**, and **ENS veneris**. If the filings of iron or of copper be mixed with sal ammoniac and strongly heated, a decomposition, greater or less in proportion to the quantity of metal employed, will take place: the ammonia will be liberated in the form of gas, while the muriatic acid will combine with the metal. The metallic muriat thus formed will sublime at nearly the same heat as the undecomposed residue of the salt, whence will result an accurate mixture of the two in the form of flowers, or a crust of a red colour: if iron filings have been used, and of a green colour if copper has been employed. The former of these is *ens martis*, the latter, *ens veneris*.

**ENSATÆ**, in *Botany*, from *ensis* a sword, alluding to their sword-shaped leaves, a name very happily applied by Mr. Gawler to the natural order of *Irides* of Jussieu, it being desirable that, if possible, every natural order should have an expressive name, independent of any particular genus it may contain; or at least that its name should not be a mere unchanged repetition of that of any such genus. This order is illustrated by the able botanist above-mentioned, in Sims and König's *Annals of Botany*, v. i. 219, and especially in Curtis's *Botanical Magazine*.

**ENSCONCED**, in the *Military Art*. See **INSCONCED**.

**ENSEELED**, in *Falconry*, a term used for a hawk which has a thread-drawn through her upper eyelids, and made fast under her beak, to obscure her sight.

**ENSEINT**, in *Law*, a term used to denote a pregnant woman.

**ENSEMBLE**, a French term, sometimes used in our language, literally signifying *together*, or *one with another*; being formed from the Latin, *in*, and *simul*.

In *Architecture*, we say, the *ensemble*, or *tout ensemble* of a building; meaning the work or composition, considered together, and not in parts; and sometimes also the relative proportion of the parts to the whole. All those pieces of building make a fine *ensemble*.

To judge well of a statue, or other work of sculpture, one must first examine whether the *ensemble* be good.

The *tout ensemble* of a painting, is that harmony which results from the distribution of the several objects of figures whereof:

whereof the whole is composed. This picture is good, taking the parts separately: but the tout ensemble is bad.

**ENSEMBLE, Fr.** together. This adverb, used substantively, and received in the French musical technica, is, according to Rousseau, invested with a very extensive signification. To regard an object in its ensemble or totality, is to consider the effect which the several parts produce, when united in a whole.

It is only in the execution of a piece of music, that this term is applicable, when the performers are so perfectly together in time and tune, seeming to be all so much animated by one soul, that they communicate exactly to the ear, all that the eye can see in the score.

The being together does not merely depend on the accuracy with which each reads his part, but in the intelligence with which he feels its peculiar character and connection with the whole; whether in the exactitude of phraseology, the precision of the movements, or seizing the instant and degree of pianos and fortes; or finally in the nice attention to such ornaments, which the author has thought so necessary as to be indispensable. It is in vain for musicians to have abilities, they can never be together without an intelligence of the author's designs, and perfectly understanding each other: for it would be impossible to keep together a band of performers that are deaf, nor in the execution of music in a style with which they are totally unacquainted. It belongs to the masters, conductors, and leaders of an orchestra, to guide, check, or accelerate individual performers, and to keep them together in the aggregate, which is always the office of a judicious first violin: who, by a certain firmness and energy in his manner, strongly impresses the character of the piece in every ear. The vocal part is subordinate to the base and the time; the first violin ought to watch and follow the voice; the ripienos should listen to and be guided by the first violin: and, finally, the harpsichord or piano forte, at an opera where the composer is supposed to sit, should be the principal and most important guide of the whole. In general, the more character there is in the style, periods, phrases, melody, and harmony, the more easy it will be to seize the ensemble; because the same idea, strongly impressed on all minds, will preside in the whole execution. On the contrary, when the music says nothing, and nothing is heard but a succession of notes without meaning: then as there is no whole to which each performer can refer his part, the ensemble goes ill.

This (says M. Rousseau) was the reason why French performers could never be together.

**ENSENE'**, called also *Infiné*, *Scheick Abadè*, and by the Arabs *Enfiné*, in *Geography*, a town of Egypt, situated towards the middle of the Saïd, east of the Nile, and dependent on the province of Achmounain, which is on the other side. Abulfeda represents it as an ancient city, surrounded by a well cultivated country, abounding in fruits and harvests. But these fertile plains have disappeared with their inhabitants, and given place to sands and deserts. See **ANTINOË**.

**ENSHMESH**, i. e. *the fountain of the Sun*, a town or fountain, which lay on the frontiers of Judah and Benjamin. (Joh. xv. 7.) The Arabians give this name to the ancient metropolis of Egypt, which the Hebrews called *On*, and the Greeks *Heliopolis*.

**ENSIFORM**, in *Anatomy*, a term equivalent to xiphoid, and meaning dagger-shaped. It is applied to the cartilage placed at the lower end of the sternum. See **TRUNK**.

**ENSIFORM Leaf**, in *Botany*, a vertical two-edged leaf like a sword, as in many species of *Iris*. See **LEAF**.

**ENSIFORM Cartilage**. Dr. Hunter remarks, that, "if this cartilage be forced inwardly by a blow, it will occasion vomiting and violent pains, by pressing against the pylorus: in this case, it would be proper to lay it bare and elevate it." However, the same eminent writer admits, that as part of the diaphragm arises from the cartilage, the latter would be likely to be drawn out of its proper situation again by the action of so powerful a muscle.

**ENSIGN**, in *Military Affairs*, is an officer whose duty it is to carry the colours; hence, when a youth first obtains a commission in the infantry, he is said to "receive a pair of colours." This is the first gradation above the rank of cadet, or volunteer, but is the lowest of all the ranks in which commissions are held, and though obtainable by purchase, cannot be realized without satisfactory recommendations, and the approval of the commander of that regiment to which the nomination is to be made. From this, of course, some deviations are occasionally admitted; but the necessity for ascertaining that none but proper persons be included within the circle of commissioned officers, occasions considerable strictness to be observed in this particular; notwithstanding which, instances have occurred of men, by no means eligible to so honourable a distinction, having obtained commissions even in some of what are technically termed "crack regiments."

The duty of an ensign requires much attention, and at times some share of bodily strength; for, on a windy day, when the colours are fully displayed, a puny person might suffer considerable inconvenience; and, indeed, at all times, though supported in a sling, the colours are rather oppressive; especially to those unaccustomed to carrying them. With regard to the station of the ensign when acting with his company, or when bearing the colours, we refer to the head of **EVOLUTION**; where the various changes of locality to which this officer is subject will be exhibited.

It is proper to remark, that although there are two stands of colours to each regiment, only one of them is properly called "the ensign." The flag, consisting of the union only, is called the king's colour, and always takes post of the other, which being in general of the same colour as the facings of the corps, and bearing any device or motto, by which it is distinguished, is appropriately called "the regimental ensign."

In case of defeat, the ensigns bearing the colours must be very careful to collect as many of the fugitives as possible for the purpose of rallying the corps, or, at least, of preventing it from being further disgraced by the loss of their facings, which formerly was an inseparable consequence annexed to the loss of the colours. This regulation certainly must often produce considerable enthusiasm; and we may reasonably conclude, that the attack made by a regiment under such a privation, (which could only be remedied by its taking the colours of their opponents,) must be of the most arduous description. In truth, we find in every walk of life, that where an imputation is to be removed, considerable energy is created by the existing disgrace; and, that the most determined resolution is formed not only to remove it, but to obtain a claim to pre-eminent consideration in future.

The pay of an ensign in the Guards is five shillings and tenpence daily; in the line, only four shillings and eightpence: a sum by no means adequate to the maintenance of a young gentleman in such style as is at present too generally prevalent in almost every regiment. So far is this carried, that many young men of considerable merit are often compelled to exchange, or even to sell out; because their finances are inadequate to bearing a share in the mess expences.

expences. Nor is it unusual for a notice to be given by the agent, or other person, to the candidate for a pair of colours, that such a certain sum annually will be needful, beyond his pay, to enable his keeping on a par with his brother officers. We are credibly informed, that in some regiments it is actually impossible for an officer to associate with his peers, unless he may possess from 500 to 1000*l.* income, over and above his allowances!

When we analyse this, we cannot but consider it to be a national evil, and that too of no small extent. We are far from wishing to see the respectability of our officers, in the smallest degree, tarnished; but it certainly cannot fail to strike, even the most superficial observer, that such an excess of expence amounts nearly to a prohibition of the middling classes, and operates in the same manner, though not so avowedly, as the ancient regime of France, which proscribed all but those of noble family, or of established descents through generations devoid of mercantile speculation, from entering within the military pale. The very dress of some corps must cost so much as to preclude the possibility of moderate fortunes being admitted. What shall we say to the charges made on a young gentleman's purse, when it is stated, that in some regiments of horse, full six hundred pounds may be required to equip him as a cornet! While an equal sum per annum, will be *in requisition* (here the term seems peculiarly appropriate) to enable him to eat, drink, and appear in the same company with his brother officers. Nor is this all; for the commission may cost a large sum, such as added to the other items would form a capital wherewith the youth might purchase an annuity, far exceeding the pay he would be likely to receive, for at least ten or twelve years. We believe the Scotch regiments are no slouches in the field, and that they bear as many good characteristics as any in our service; yet their dress is generally very plain, and their fare very far from sumptuous. They are born economists; and from being brought up in a hardy, active routine, are capable of enduring great fatigue, and of putting up with various privations, which, to a person brought up with less ceremony, and habituated to the enjoyment of various luxuries, might be at least unpleasing, if not absolutely distressing.

The Turkish ensigns are horses' tails; the number of which distinguishes the rank of their commanders; the sultan has seven, the grand vizier only three, &c. Those of the Europeans are pieces of taffety, with divers figures, colours, arms, and devices, thereon. Xenophon tells us, that the ensign borne by the Persians was a golden eagle on a white flag; the Corinthians bore the winged horse, or Pegasus; the Athenians, an owl; the Messenians, the Greek letter M; the Lacedæmonians, the A.

The Romans had a great diversity of ensigns; the wolf, minotaur, horse, boar, and at length the eagle. See *SIGNA*.

A military ensign, on a medal of a Roman colony, denotes it a colony peopled with old soldiers.

*ENSIGN*, in *Naval Affairs*, is the large flag hoisted at the stern of a ship, whether of war or in the merchant service, and denotes the country to which she appertains, or the government under whose protection and authority she is navigated. Of the several distinguishing ensigns, a more ample description will be found under the head *FLAG*: we shall briefly observe in this place, that this, as well as most of the colours of ships, whether *jacks* or *pennants*, are commonly constructed of hunting, and, that it is usual to make them so ample as to occupy two-thirds of the flag-staff in height, and to give them depth enough just to touch the surface of the water, when in a quiescent state. All ensigns

are hoisted with their unions, or distinguishing cantons, uppermost, next to the truck on the head of the flag-staff: when hoisted in the shrouds with the union, or distinguishing canton, lowermost, so as to reverse all the figures, decorations, or inscriptions, it is indicative of distress. The liberality of some nations has been conspicuous in forbearing from making prizes of vessels so circumstanced, provided their commanders have engaged to return to the nearest port, without intermediately offering any violence to such as they might meet, there to remain in ordinary until the conclusion of the war.

The display of an ensign in presence of a strange sail is generally considered a mark of civility during times of peace, and in times of war serves to distinguish between friends and foes. During the latter period, such vessels as do not hoist their ensigns may be reasonably suspected to be privateers, or to be desirous of evading every kind of communication. So long as the ensign remains hoisted, during an engagement, the ship is to be considered in a state of defiance; but when it is lowered, she is said to strike; that is, to give up the contest, and to submit, as a prize to her opponent. It occasionally happens that a ship's ensign staff, or the halyards by which the ensign is hoisted to the mizen-peak, is shot away; this does not indicate submission; on the contrary, the annals of warfare exhibit many instances of extraordinary courage in individuals, who, at such moments, have ran aloft, or even stood on the poop, there to sustain a portion of the ensign as a token of the most determined opposition. In the British service we have three ensigns, namely, the white, the red, and the blue; the first is divided into equal portions, by a broad St. George's cross of red, of which the upper canton, or quarter, is filled up with the union. The second and third are both plain, with the exception of the union in the same canton. These several ensigns indicate the rank of the admiral under which a ship of war is commissioned, or employed. Thus, an admiral of the white bears a white, or, as it is commonly called, a St. George's ensign, at the main top-gallant mast head; a vice admiral of the white has one at the fore top-gallant mast head; and a rear admiral one at the mizen top-gallant mast head; the same rules of precedence obtain, with the admirals, vice-admirals, and rear-admirals of the red and blue respectively; each bearing a flag of his proper colour at that mast head corresponding with his rank. When fleets are separated into squadrons or divisions, each ship assumes for the time the ensign of that admiral who commands the squadron, or division, in which it acts. The same is observed by all vessels acting under any particular port-admiral; all under his authority invariably bearing an ensign conformable to his designation, whether of the white, red, or blue.

*ENSIGNCY*, denotes the rank of that officer who bears the ensign or colours of a regiment of foot; and corresponds with that of "cornet" in the cavalry, and of "second-lieutenant" in the artillery. It is, perhaps, one among the curious anomalies which pervade many parts of our system, that an ensigncy should exist in the engineer department, there being no colours to be carried in that corps, while the colours of the artillery battalions are borne by the second lieutenants.

An ensigncy in a marching regiment may generally be obtained for about three hundred pounds, when serving within the realm: but in various situations abroad, especially in the East Indies, where an increase of pay is given, the price is usually much higher. See *ENSIGN, military*.

*ENSISHEIM*, in *Geography*, a handsome town of France, in the department of the Upper Rhine, in the district of Colmar, with a population of 1809 individuals. It

is situated on the river Ill, 12 miles N. of Mulhausen, 12 miles S.W. of Brisack, 294 miles S. by E. of Paris. N. lat. 47° 52', and is the chief place of a canton, which has a territorial extent of 257½ kilometres, 17 communes, and 10,122 inhabitants.

ENSTASIS, *Ἐνστάσις*, of *εν* and *ἵστημι*, *statio*, in *Logic*, a manner of replying to an opponent, either by confuting his argument, or denying the justness of his conclusion. Voff. Rhet. lib. iii. p. 380.

ENSTASIS, in *Medicine*, a term used to express the ingress of molecule into the vacuity of the pores which obstruct them, and thereby cause diseases. It is a word familiar with Erasistratus and Asclepiades, who was a follower of Democritus, and taught that most diseases were caused by such an ingress of matter into the pores. Thus Asclepiades defined a phrenzy to be such an entasis in the membranes of the brain. Plutarch, in his precepts of Health, also mentions this entasis: and Galen and Cassius, who is supposed to have been of the sect of the Rationalists, expresses the same sense by the same word.

ENSTORF, in *Geography*, a town of Germany, in the circle of Bavaria and Upper Palatinate; 22 miles N. of Ratibon.

ENT, *Sir GEORGE*, in *Biography*, an eminent physician, was born at Sandwich, in the county of Kent, on the sixth of November, 1604. After going through the usual course of classical instruction, he was sent to Sidney college, in Cambridge. He afterwards travelled to the foreign seats of learning, received the degree of doctor of physic at Padua, and on his return was incorporated in the university of Oxford, on the seventh of November, 1638. During the usurpation of Cromwell he settled in London, where he obtained considerable eminence in the practice of his profession: he was elected a fellow, and afterwards president of the College of Physicians; and at length his merits were rewarded with the honour of knighthood by king Charles II. He enjoyed for a long period the esteem and confidence of the public, and died at the age of eighty-five, on the 13th of October, 1689. He was buried in the church of St. Lawrence in the Jewry. He was a very intimate friend of the celebrated Dr. Harvey, and wrote a defence of his great discovery, entitled "Apologia pro circulatione sanguinis contra Æmilium Parisanum," which was published in 8vo. in the year 1641, and again in 4to. in 1685. About 1651 he prevailed with Dr. Harvey to consent to the publication of his "Exercitationes de generatione animalium," which he superintended, and presented to the College of Physicians in a sensible and elegant dedication. He likewise published a treatise of his own in 1679, which was reprinted in 1682, entitled, "Animadversiones in Malachiz Thruston, M. D. diatribam de respirationis usu primario," in 8vo. His works were collected, and published in one volume 8vo. at Leyden in 1687, under the title of "Georgii Entii Opera omnia Medico-Physica, &c.:" and after his death, his "Observationes ponderis testudinis, cum in autumnno terram subiret, cum ejusdem ex terra verno tempore exeuntis pondere comparati, per plures annos repetitæ," were printed in the Philosophical Transactions, N° 194, anno 1691. See ELOY Dict. Med. Biog. Dict.

ENTABLATURE, in *Architecture*, is that part of an order of column which is over the capital, comprehending the architrave, frieze, and cornice.

The word seems formed of *tabulatum* or *intabulamentum*.

The entablature is also called the *trabeation*, and by Vitruvius and Vignola *ornament*. It is different in the different orders; indeed, it consists of the three grand parts or divisions above-mentioned, in all; but those parts consist

of a greater or less number of particular members or subdivisions, as the orders are more or less rich.

Vignola makes the entablature a quarter of the height of the whole column, in all the orders.

In the Tuscan and Doric, the architrave, frieze, and cornice, are all of the same height; in the Ionic, Corinthian, and Composite, the whole entablature being fifteen parts, five of them are allowed for the architrave, four for the frieze, and six for the cornice. See IONIC, CORINTHIAN, &c. and COLUMN.

ENTABLATURE, or *Entablament*, is sometimes also used for the last rows of stones on the top of the wall of a building, whereon the timber and covering rest.

As this is frequently made to project beyond the naked of the wall to carry off the rain, some authors call it in Latin *stillicidium*, or *drip*. Such an entablature does not stand out far enough; it lets the water fall on the foot of the wall.

ENTABLER, in the *Manege*, is said of a horse whose croupe goes before his shoulders, in working upon volts; for, in the regular manege, one-half of the shoulders ought to go before the croupe. Thus we say, your horse entables; for, in working to the right, he has an inclination to throw himself upon the right heel; which fault you may prevent, by taking hold of the right rein, keeping your right leg near, and removing your left leg as far as the horse's shoulder. A horse cannot commit this fault without committing that called *aculer*; but *æuler* may be without entabler.

ENTAIL, in *Law*, signifies *fee tail*, or *fee entailed*, that is, abridged, curtailed, or limited to certain conditions. For the docking of an entail, see DOCKING and RECOVERY. See TAIL and ESTATE, &c.

ENTALIUM, the *pipe-shell*, in the *Materia Medica*, a shell of the same genus with the dentalia, being a species of the tubuli marini. It is frequent in the East Indies, and sometimes is found on our own shores. The virtues ascribed to it are the same with those of the dentalium; but neither of them have any title to more than those of alkaline absorbents, like the other testaceous powders.

ENTE, in *Heraldry*, literally implies *engrafted*, and is used by foreign heralds to express a method of marshalling, little known among us; yet we have an instance of it in the fourth grand quarter of his majesty's royal ensign, whose blazon is Brunswick and Lunenburgh, impaled with ancient Saxony, *enté in pointe*.

ENTELECHIA, *Ἐντελεχία*, of *εντελεχεια*, *perfect*, a Greek term, by which Aristotle defines the soul; and which, not occurring in any other author, has given the critics and philosophers infinite perplexity to discover its true meaning. See SOUL.

Hermolous Barbarus is even said to have consulted the devil about it; after which, in his paraphrase on Themistius, whether from the devil or himself, we know not, he renders it by *perfectihabia*, which is not a whit the clearer.

Cicero, whose interpretation should be preferable to that of any modern, defines entelechia (Tusc. Quest. lib. i. cap. i.) to be, "a certain, continued, and perpetual motion;" whence it should seem, that Aristotle took the soul for the mode of the body; a continuous motion being, doubtless, a mode of body.

The common Peripatetics hold entelechia to signify act, and under it suppose the form of the compound or animal to be understood.

Lastly, others, and those the latest Peripatetics, agree, that the act, or entelechia, whereby Aristotle meant to explain

plain the nature of the soul, is either some mode of the body, as motion, or it is nothing.

ENTENDEMENT, in *Law*. See INTENDMENT.

ENTER, *To, a Hawk*, among *Sportsmen*, is used of a hawk when the begins to kill.

ENTER, *To, a Hound*. See ENTRANCE of Hounds.

ENTERADENES, of *εντερον*, *intestine*, and *αδην*, *gland*, in *Anatomy*, a name by which many authors have called the intestinal glands.

ENTERENCHYTÆ, of *εντερον*, *the viscera*, and *εγχυσις*, *Infuse*, in *Medicine*, a name given by authors to the several instruments contrived for throwing clysters into the bowels; such as the bladder and pipe the syringe, and the like, for liquid clysters; and the box with the double pipe for conveying the smoke of tobacco. See CLYSTER, and FUMIGATOR.

ENTERFERING, in the *Manege*. See CUTTING.

ENTERITIS, in *Medicine*, from *εντερον*, *intestine*, signifies an inflammation of the intestines. The disease has been variously denominated *ileus*, *ιλιοσ*, *iliac passion*, *chor-dupfus*, &c.

The symptoms of inflammation of the bowels generally come on suddenly. An acute and fixed pain, with a sense of heat in the abdomen, more especially about the umbilicus or navel, often with a feeling of twisting in that part, attacks the patient; this pain is increased by pressure. Previously to its occurrence, or together with it, the usual symptoms of fever come on, such as rigor or shivering, followed by flushes of heat, thirst, and dryness of the tongue; the pulse becomes frequent, hard, and commonly small; considerable anxiety ensues; the bowels are obstinately costive; the stomach is soon deranged; and eructations, nausea, and vomiting succeed. As the disorder advances, the pain becomes more acute, without any disposition to evacuation; the abdomen becomes distended with flatulence, and more tender under pressure; and the urine is often voided with difficulty and pain. If the inflammation be not alleviated, gangrene generally ensues, often within twenty-four hours from the commencement of the disease, and terminates the life of the patient.

The occurrence of gangrene is indicated by a sudden remission of the pain, while, at the same time, the strength fails, the pulse sinks, the voice grows feeble, the countenance shrinks, and assumes even a cadaverous aspect, yet the distension of the belly is not diminished, but often increased. This tendency to terminate speedily in mortification constitutes the great danger of inflammation of the intestines. Sometimes the disease terminates in suppuration, which, though less rapidly fatal, most commonly wears out the patient's strength and life in a lingering manner; but occasionally this condition ends in recovery. The formation of pus is indicated in this disease, as in other internal inflammations, by the remission, but not total cessation of the pain, and by the occurrence of frequent fits of rigor, and sometimes by a purulent discharge by stool. But the disease, especially when the aid of medicine is early and actively obtained, frequently terminates favourably, by resolution, as it is called; *i. e.* by a gradual diminution and cessation of the symptoms. If the pains abate gradually, and the tenderness and distension of the abdomen lessen, while the pulse becomes softer and fuller, natural evacuations of feculent matters are passed, and a free general perspiration breaks out, this favourable termination may be anticipated. Whereas, the continuance of the constipation, and of the fixed pain, the increase of the sickness and vomiting, the occurrence of the symptoms just described as indicative of gangrene, especially if accom-

panied with hiccup and cold sweats, are among the unfavourable prognostics.

The principal source of mistake, into which the practitioner is likely to fall in treating this disease, is in confounding it with *colic*; a spasmodic disorder, which requires a treatment essentially different, but which, nevertheless, occasionally terminates in enteritis. The diagnostic symptoms of the two complaints have been already stated at length, under the former article. See COLICA.

Enteritis occurs most commonly in persons somewhat advanced in life, generally after the age of forty, or fifty; and it seems to be most frequent in plethoric habits, and in those particularly who indulge in indolence and full living. In some individuals there appears to be a constitutional irritability of the intestines, which renders them liable to attacks of inflammation, upon the application of slight causes.

The exciting causes of enteritis are various; among the most common are obstructions in the bowels, which necessarily retain the feces, until these, by their quantity or quality, become extremely irritating, and excite inflammation. These obstructions to the passage of the stools through the intestinal canal are occasioned by different circumstances. A spasmodic contraction of any part of the canal, as in *colic*, if it continue for any considerable time, is liable to induce inflammation: a stricture, occasioned by a chronic thickening of the coats of the bowels, sometimes brings it on: *intro-susception*, or the inverted passage of one part of the gut into the adjoining part, produces a similar effect; as well as the strangulation of the intestine from *hernia*, or rupture: the formation of calculus in the intestinal canal, which, though a rare occurrence, sometimes takes place, may also occasion a similar obstruction, and consequent inflammation. Enteritis is likewise excited by irritating substances conveyed into the intestines, which, by their bulk, shape, or indigestibility, or by their chemical or specific acrimony, produce much excitement in the canals. Thus, the swallowing of hard kernels, seeds, or stones of fruit, or pieces of metal, &c. has often induced the disease; and the presence of *scybala*, or hardened feces, and of calculous concretions, operates partly by the immediate irritation which they occasion. Thus also, strong concentrated acids or alkalis, spirituous liquors, high seasoned food in large quantities, drastic purgatives, worms, &c. in the intestinal canal, have excited inflammation in it in different instances. Hence the disease has sometimes been the immediate effect of repletion, or of a fit of intoxication: and even a mild cathartic, when the bowels were loaded with much hardened feces, which the medicine was incapable of removing, has, in some rare cases, produced inverted motion and *intus-susception*, terminating in enteritis. A very common cause of inflammation in the bowels is the application of cold to the legs and feet, or to the abdomen itself, especially if sudden or long continued. The retrocession of gout, rheumatism, erysipelas, or chronic eruptions, from the external parts, is sometimes followed by symptoms of intestinal inflammation.

In the *cure* of enteritis, as in all other acute inflammatory diseases, the leading object is to remove the inflammation, from which all the other symptoms of the disease originate. This, though apparently an identical proposition, cannot be too strongly inculcated, in the treatment of enteritis; because the excessive constipation of the bowels, which, in common with the rest of the symptoms, is in general merely an effect of the inflammatory condition of the bowels, in some part, is often attacked by the inattentive practitioner with active purgative medicines, as if it were the primary object, and the source of all the mischief. The inflammation

tion is to be subdued by blood-letting, from a large orifice, to an extent which must be various according to the constitution of the patient, and the violence of the symptoms. This depletion may be aided in its effects by the application of leeches, and afterwards of a blister to the abdomen; and by the strictest abstinence from all stimulating and nutritious aliment. The blood-letting must be repeated in a short time, if the symptoms do not abate, and the strength of the patient is sufficient to support the evacuation; which can only be determined by the observation and experience of the practitioner. If the pulse should become fuller and less wiry after the operation, it will afford a strong reason for the repetition of it, should the continuance of other symptoms appear to require it. The use of emollients externally was in great vogue among the ancients; and fomentations, or, what is better, the warm bath, may be resorted to with advantage. Celsus recommends the use of warm cataplasms, frequently changed, and covering the greater part of the trunk, "à mammis usque ad inguina et spiniam," and also a bath of warm oil;—"demittere totum hominem in calidum oleum." De Medicinâ, lib. iv. cap. 13. The dirty applications of living animals, or the skins of those recently killed, can only operate as emollients, and are necessarily less effectual than fomentations; they are at present, therefore, fallen into disuse. Sydenham recommended the application of a live whelp to the abdomen in these cases. Opera, sect. i. cap. 4. p. 77. Edit. Lugd. 1726.

It must be obvious, that before the inflammation of the intestines is lessened or removed by these measures, any additional irritation to the membranes, already in an acute state of sensibility, whether by the immediate stimulus of a cathartic medicine, or by the contents of the bowels being forced forwards to the inflamed part, must tend to aggravate the disorder, rather than to relieve it. In fact it is usually found, that purgatives, given by the mouth, are not successful, where this previous diminution of the inflammation has not been effected. And when this has been accomplished, some of the milder purgatives, as the neutral salts, should first be administered, the action of the intestines downwards being at the same time solicited by emollient glysters, which also contribute to the same relaxant purposes as the external fomentations. Dr. Gregory used to remark, in his lectures, that a purgative medicine had often been known to operate as soon as a blister, applied to the belly, began to rise, which had not acted previously: and this observation is still more commonly verified, after a free evacuation by blood-letting. See Edinburgh Med. and Surg. Journal, vol. i. p. 64. Some practitioners have attempted to open a passage for the fæces, by mechanically distending the large intestines, by throwing up five, six, or seven pints of warm water with an injecting syringe. This expedient may be useful in spasmodic colic; but it is objectionable, in enteritis, on several grounds. Such distension can only be accomplished in the colon, or great gut; whereas the obstruction by inflammation is commonly in some portion of the small intestines, and therefore out of the reach of the enema. In the next place, any forcible distension of an inflamed and thickened canal, if it could be accomplished, would rather conduce to an increase of the inflammatory condition, than to lessen it by the removal of fæces. In a word, all measures applied to the inflamed intestine should be mild; since forcible ones cannot but augment the inflammation, upon which the impeded function of the organ depends. By way of glyster, therefore, a little common salt, magnesia vitriolata, or infusion of fenna, with gruel or warm water, will probably answer every good purpose that can be expected from such an expedient. Tobacco smoke has been often injected when

milder means have failed, or infusions of tobacco; but their success, we believe, has not been often experienced. Indeed tobacco injections are liable to produce great sickness and irritation, if that herb be not used in very small quantities.

The extreme sickness which often accompanies enteritis, and by which every thing that is taken into the stomach, whether liquid or solid, is rejected, renders it difficult, in some cases, to produce any effect upon the bowels by internal medicine. In this case, the irritability of the stomach may be quieted by the saline effervescent draught, or by a small opium pill, or, if this be rejected, by an opiate given in a glyster; after which the necessary laxative medicines may be retained, and accomplish the intended object. It should be observed, however, that the stimulus of opium will prove rather injurious than useful, while the inflammation is unsubdued.

Where the inflammation has arisen from strangulated hernia, the operation, by which the strangulation is removed, and the intestine returned into its place, can alone save the life of the patient. See HERNIA.

We have already had occasion to allude to a remedy for constipation of the bowels, which has been recommended as a last resource, namely, a quantity of crude quicksilver; and to point out the absurdity of the hypotheses, which have led to its use, as well as some of the ill consequences of it. Sydenham reprobates the practice, which appears to have been first adopted about his time. Loc. cit. p. 76. See CONSTIPATION.

When the inflammation of the intestines has been subdued, the utmost caution should be employed, with a view to the prevention of a relapse, to which the convalescent from enteritis is extremely liable. A thin, spare, and laxative diet, consisting of vegetable substances, of gruels, or barley water, or these mixed with milk, must be adhered to most rigidly for a considerable time after recovery; and all acrid, stimulating substances, or those which are difficult of digestion, should be most scrupulously avoided. The most fatal effects have been observed to take place, in some instances, from returning too soon to ordinary diet, after the removal of inflammation of the bowels. In order to guard against a future recurrence of the disease, the application of cold to the abdomen and feet should be prevented by warm cloathing; and the occurrence of costiveness at all times avoided, by laxative diet or medicine, so that no accumulation of fæces can take place, and the steady action of the bowels be constantly preserved.

ENTERMEW. See FALCON.

ENTEROCE'LE, (from *εἰστρον*, an intestine, and *κελε*, a tumor, or rupture,) in Surgery; a hernia is so termed, when its contents are entirely composed of intestine.

ENTERODYNIA, from *εἰστρον*, intestine, and *δύνη*, pain, in Medicine, a term used by some writers, as nearly synonymous with colic, but expressing a minor degree of pain; such, for instance, as arises from the irritation of vitiated bile, loaded bowels, worms, &c. and which, therefore, laxative medicines generally relieve.

ENTERO-EPIPOCE'LE, (from *εἰστρον*, an intestine, *επιπλοον*, the omentum, and *κελε*, a tumor,) in Surgery, a term applied to a hernia, which contains both a portion of the bowels, and a piece of the omentum.

ENTERO-HYDROCE'LE, (from *εἰστρον*, an intestine, and *υδροκελη*, a dropsy of the scrotum,) a scrotal hernia, containing a good deal of fluid.

ENTEROLOGY, from *εντερον*, intestine, a gut, and *λογος*, sermo, discourse,) is properly a treatise of the bowels. Though the word is generally understood to include the

contents of three cavities, head, breast, and all the viscera or belly.

**ENTEROMPHALOS**, (from *εντερον*, an intestine, and *ομφαλος*, the navel,) a hernia at the navel, and containing intestine.

**ENTERORAPHÉ**, (from *εντερον*, an intestine, and *ραφη*, a suture,) a suture of the bowels.

**ENTEROSCHEOCELE**, (from *εντερον*, an intestine, and *σχοκολλησις*, a rupture, or hernia situated in the scrotum,) a scrotal hernia, the contents of which are entirely composed of intestine.

**ENTERPEN**, *To*, in *Falconry*, is a term applied to a hawk, when her feathers are wrapped up, snarled, or entangled.

**ENTERPLEADER**, in *Law*. See **INTERPLEADER**.

**ENTERPRISE**, denotes an undertaking attended with some difficulty and danger.

**ENTERPRISE**, in *Military Affairs*, appertains rather to those desultory expeditions which often prove of considerable importance in their consequences; though, perhaps, apparently trivial, when compared with those great events that sometimes characterize a campaign. In some instances we see the most decided effects produced by the operations of enterprising partisans, who, exclusive of the quantity of forage, and the intelligence they generally afford, distress the enemy severely, by compelling him to act with such circumspection, and so to strengthen his positions, as inevitably must weaken his other operations, as well as create considerable alarm among his troops, especially when detached in exposed situations.

In some countries; detached enterprises seem to constitute the chief incidents in warfare; thus, we find that irregular corps commanded by baron Trenck were peculiarly active, and harassed the enemy beyond measure! Thus, also, the Croats, the Pandours, and the Pindaries, of the Mahratta empire, the Sooties under the late Tippoo, and various other such predatory establishments, commanded by officers of a suitable disposition, have ever been famous for annoying, and for cutting off the supplies of their adversaries.

No enterprise, whether military or naval, should be entrusted to the charge or conduct of an individual deficient in any one of the requisites for such a responsible, and, indeed, so arduous an appointment. In the first place, a knowledge of the geography of that country he is to invest, and of the language of its inhabitants, is indispensably requisite. His character for marked personal courage, and for the prompt application of suitable remedies against every species of disaster, or of disappointment, should be conspicuous. He should possess that kind of deportment which preserves the strictest subordination, while it secures the affection, and excites the admiration, of all under his command. He should be expert in all military exercises, and possess both an active mind, and the soundest constitution. With such valuable gifts, added to a certain conciliatory mode of conduct towards the peasantry, &c. of the district in which he is to carry on his enterprises, a partisan may perform wonders, and far outdo all the exploits an equal number of regulars could achieve under a less capable leader. The truth is, that, generally speaking, soldiers and sailors are mere automatons, acting under the direction of an expert machinist, whose character is ever appreciated according to the success of his movements. How far permanent reputation may be established by the commander of such an auxiliary force, may be collected from that dread which was created by the Tarleton legion among the Americans, during their struggle with the mother country. That legion, even at

this day, are spoken of in terms of admiration, by the very people who suffered so severely from the exertions and abilities of its commander.

It being obvious that, on many occasions, an army must depend greatly for supplies on the activity and talents of a partisan, we cannot too forcibly point out the peremptory necessity which exists, for the rejection of all who may be deficient in the above qualities, without which, it is unreasonable to expect that any enterprise of moment should ever be safe to those who might be employed; much less could it be of service to those in whose behalf it might be undertaken. Naval enterprises require no less attention in some cases; though, for the most part, we find them rather indebted for success to undaunted bravery, and a moderate portion of judgment. These ordinarily are made under cover of, or supported by, some sufficient force; whereby, in case of defeat, they are rescued from total ruin: whereas, the military partisan rarely has such protection at hand.

**ENTERSOLE**. See **MEZANINE**.

**ENTERTAIN**. This term has, no doubt, crept into military phraseology in consequence of the entertainment afforded at public-houses, &c. to such candidates as prefer a scarlet coat and a musket, to a frock and a pitch-fork. We cannot sufficiently express our regret, that no better mode has been ordinarily brought into practice, than that of plying men with liquor for the purpose of inducing them to enlist. We are, indeed, rather infidels on the subject of any numerous accessions to the real strength of our armies, in consequence of this custom: for we have had occasion to learn, that a very large portion of the recruits obtained in consequence of inebriety, either abscond at some favourable moment, or prove to be the worst soldiers in their regiment. If drunkenness has been habitual to them, they rarely relinquish their addictedness to liquor; and if, on the contrary, they had, until the moment of being enlisted, been of a sober disposition, their peace of mind is totally destroyed, and they serve without alacrity, without zeal, and generally, too, without health: they are often known to fall a prey to remorse!

We are sensible that, speaking abstractedly, the affording of entertainment to persons who appear desirous of enlisting, may be defended under the plea of state necessity; but it becomes a very serious question, whether the nation does not pay considerably more in consequence of the monies expended in this way? also, whether it is sound policy to allow military persons to be in any shape concerned in overwhelming the senses of that man, who is to be for life associated with them, and who will not always be unmindful of the condition to which they may have brought him? To condemn a practice, said to be so necessary towards our safety as an independent nation, without offering a substitute of a more favourable description, might, perhaps, justly subject us to the imputation of presumptuously branding the existing custom with obloquy; we shall, therefore, briefly remark, that, in all probability, not only as many, but more, valuable recruits would be obtained by desisting from what is vulgarly called *entertaining* the candidates; and from expending a very large portion of his bounty in liquor, race-shows, and such dissipations as "make him poor indeed!" In place of this, let the whole of his bounty-money be given to the parish from which he may have been taken, for the support of his family; and let the recruit himself be subsisted and clothed entirely at the expence of the state. Should the recruit have no family subject to parochial aid, or likely to be so, let his bounty money be reserved until he should have served a certain time, and then to be given to him in instalments: so that he might not dissipate the whole adventitiously,

ventitiously, and that he should be enabled, from time to time, to provide himself with various articles of apparel, or of comfort, suited to his profession.

We cannot close this subject without strongly reprobating the practice of stopping certain sums, for off-reckonings, and necessaries. If the soldier is to pay for them, let it be by a plain and peremptory reduction of his pay, in exchange for which he should receive certain articles from government; but let there be no account-current between the soldier and his officer, for feathers, lace, buckles, canteens, knapsacks, and such like: this kind of dealing sets aside that respect which the former ought always to entertain for the latter, and, not unfrequently, occasions a certain kind of suspicion by no means tending to promote either esteem or subordination. While reform seems to be the order of the day, it may, perhaps, be at least fashionable, if not praiseworthy, to point out this as an instance in which much melioration might be very easily, and safely, effected.

ENTERTAINMENTS, *epulae*, among the ancients, were of various kinds, as, 1. Funeral entertainments, *epulae funebres*. 2. Entertainments given by the husband on bringing home his wife, called *epulae geniales*. 3. Those bestowed on the soldiers, called *epulae militares*; which was done before or after an engagement, or on occasion of proclaiming the general imperator. 4. Birth-day entertainments, *epulae natalitiae*.

There were many other kinds, denominated either from the place where, the persons by whom, or the occasion for which they were given.

INTERVIEW, in *Falconry*, a term used for the second year of a hawk's age.

ENTHALIUM, in *Natural History*, a name given by some to a species of the tubuli marii, more usually known by the name of penicillum marinum, and pinceau de mer. See *PENICILLI Marini*.

ENTHUSIASM, *Εθουσιασμος*, a poetic, or prophetic rage or fury, which transports the mind, inflames and raises the imagination, and makes it conceive and express things extraordinary and surprising.

The word is derived from the Greek, *εθεος*, or *εθευς*, a man animated in an extraordinary manner with the spirit of God; in whom God is, or whom God animates. Whence the verb *εθεουσαζω*, or *εθεουσαω*, and the noun *εθεουσιασμος*, *enthusiasm*: and *εθεουσιαστης*, *enthusiast*, a person subject to such transports.

M. de Piles defines enthusiasm to be a transport of the mind, whereby it is led to think and imagine things in a sublime, surprising, yet probable manner.

The sublime he thinks a necessary ingredient in the definition, as being the proper effect and production of enthusiasm.

This is the enthusiasm felt in poetry, oratory, music, painting, sculpture, &c. (see the next article); but this enthusiasm which belongs to the works of art, is very different from that attributed to the sibyls and priestesses of the oracles, and heathen gods, which was little else but fanaticism, and consisted principally in grimace, and contortions of the body. See *ORACLE* and *PYTHIAN*.

There is a degree of assent, says Mr. Locke, which, with some men, has the same authority as either faith or reason; and that is enthusiasm, which, laying by reason, would set up revelation without it; whereby, in effect, it takes away both reason and revelation, and substitutes in the room of it the ungrounded fancies of a man's own brain, and assumes them for a foundation, both of opinion and conduct.

Immediate revelation being a much easier way for men to

establish their opinions, and regulate their conduct by, than the tedious labour of strict reasoning; it is no wonder, that some have been very apt to pretend to it: especially in such of their actions and opinions as they cannot account for by the ordinary methods of knowledge and principles of reason. Hence we see, that in all ages men in whom melancholy has mixed with devotion, or whose conceit of themselves has raised them into an opinion of a greater familiarity with God than is allowed others, have often flattered themselves with the persuasion of an immediate intercourse with the Deity, and frequent communications with the Divine spirit.

Their minds being thus prepared, whatever groundless opinion comes to settle itself strongly upon their fancies, is an illumination from the spirit of God; and, whatsoever odd action they find in themselves an inclination to do, that impulse is concluded to be a call or direction from heaven, and must be obeyed.

This we take to be properly enthusiasm; which, though rising from the conceit of a warm and over-weening brain, works, where it once gets footing, more powerfully on the persuasions and actions of men than either reason or revelation, or both together; men being most forwardly obedient to the impulses they receive from themselves.

When men are once got into this way of immediate revelation, of illumination without search, and certainty without proof, reason is lost upon them; they are above it; they see the light infused into their understanding, and they cannot be mistaken: like the light of bright sun-shine, it shews itself, and needs no other proof but its own evidence; they feel the hand of God moving them within, and the impulses of the spirit, and cannot be mistaken in what they feel. But, of this seeming and feeling, it is a perception of an inclination to do something, or of the Spirit of God moving that inclination: these are two very different perceptions, and should be carefully distinguished.

If they know the thing to be a truth, they must do it, either by its own self-evidence, or by the rational proofs that make it out to be so: if they know it to be a truth, either of these two ways, they in vain suppose it to be a revelation; for thus, all truths, of what kind soever, which men uninspired are enlightened with, come into their minds. If they say, they know it to be true, because it is a revelation from God, the reason is good; but then it will be demanded, how they know it to be a revelation from God? If they say, by the light it brings with it, they should consider, whether this be saying any more than that it is a revelation, because they believe it to be true; for all the light they speak of is but a strong persuasion of their own minds that it is a truth, which is a very unsafe ground to proceed on, either in our tenets or actions. True light in the mind is nothing else but the evidence of the truth of any proposition; and if it be not self-evident, all the light it can have is from the clearness of those proofs upon which it is received. See *EVIDENCE*.

God, when he makes the prophet, doth not unmake the man; he leaves his faculties in their natural state, to enable him to judge of his inspirations, whether they be of divine original or not. If he would have us assent to the truth of any proposition, he either evidences that truth by the usual methods of natural reason, or else makes it known to be a truth which he would have us assent to by his authority; and convinces us that it is from him, by some marks which reason cannot be mistaken in. *Essay on Hum. Underst.* book iv. chap. 19.

The holy men of old, who had revelations from God, had something else besides internal light, of assurance in their

## ENTHUSIASM.

their own minds, to testify to them that it was from God; they had outward signs to convince them of the Author of those revelations; and when they were to convince others, they had a power given them to justify the truth of their commission from heaven; and by visible signs, to assert the divine authority of the message they were sent with. Moses saw the bush burning without being consumed, and heard a voice out of it. God, by another miracle, of his rod turned into a serpent, assured him likewise of a power to testify his mission, by the same miracle repeated before those to whom he was sent.

Enthusiasm is defined by Dr. Hartley (*Obs. on Man*) to be a mistaken persuasion in any person, that he is a peculiar favourite with God; and that he receives supernatural marks thereof. The vividness of the ideas of this class easily generates this false persuasion in persons of strong fancies, little experience in divine things, and narrow understandings, (and especially where the moral sense, and the scrupulosity attending its growth and improvement, are but imperfectly formed,) by giving a reality and certainty to all the reveries of a man's own mind, and cementing the associations in a preternatural manner. It may also be easily contracted by contagion, as daily experience shews; and indeed more easily than most other dispositions, from the glaring language used by enthusiasts, and from the great flattery and support which enthusiasm affords to pride and self-conceit. The ingredients, says lord Lyttelton in his "Observations on the Conversion, &c. of St. Paul," of which enthusiasm is generally composed, are great heat of temper, melancholy, ignorance, credulity, and vanity, or self-conceit.

The true sources of enthusiasm, says Mr. Hume in his "Essay on Superstition and Enthusiasm," are hope, pride, presumption, a warm imagination, together with ignorance. From the influence of these causes arise raptures, transports, and surprising flights of fancy; and whilst confidence and presumption still increase, these raptures, being altogether unaccountable, and seeming quite beyond the reach of our ordinary faculties, are attributed to the immediate inspiration of that Divine Being, who is the object of devotion. In a little time the inspired person comes to regard himself as a distinguished favourite of the Divinity; and when this phrensy once takes place, which is the summit of enthusiasm, every whimsy is consecrated. Human reason, and even morality, are rejected as fallacious guides; and the fanatic madman delivers himself over, blindly, and without reserve, to the supposed illapses of the spirit, and to inspiration from above.

Devotion, undirected, or unrestrained by reason, degenerates into enthusiasm, or a religious phrensy, founded in an apprehension of a present Divine energy on the mind, to which all its powers are supposed to be subject, and by which a person is carried on without attention to any thing else as his guide, and producing not only great perturbation of mind, but most amazing agitations of body. Many instances of this kind occur, both in ancient and modern times, to the disgrace and injury of rational religion.

Mr. Hume (*ubi supra*) makes several reflections concerning the different influences of enthusiasm and *superstition* (which see) on government and society. He observes, *first*, that superstition is favourable to priestly power, and enthusiasm not less, or rather more, contrary to it than sound reason and philosophy. He observes, *secondly*, that religions, which partake of enthusiasm, are, on their first rise, more furious and violent than those which partake of superstition; but in a little time become more gentle and moderate. When enthusiasm rises to that height as to inspire

the deluded fanatic with the opinion of divine illuminations; and with a contempt for the common rules of reason, morality, and prudence, it produces the most cruel disorders in human society; but its fury is like that of thunder and tempest, which exhaust themselves in a little time, and leave the air more calm and serene than it was before. When the first fire of enthusiasm is spent, men naturally, in all fanatical sects, sink into the greatest remissness and coolness in sacred matters; there being no body of men among them, endowed with sufficient authority, whose interest is concerned to support the religious spirit: no rites, no ceremonies, no holy observances, which may enter into the common train of life, and preserve the sacred principles from oblivion. For the influence of superstition, see that article. He observes, *thirdly*, that superstition is an enemy to civil liberty, and enthusiasm a friend to it.

ENTHUSIASM, in *Poetry, Eloquence, and Elocution*, is a species of rapturous elevation and fervour, which transports the writer or speaker beyond the limits of apparent rule, and mere methodical propriety. Like genuine sublimity, to which it is very nearly allied, and with which it occasionally co-operates, in producing the highest impressions that can result from human eloquence, it defies, perhaps, the exactness of logical definition; its very essence consisting in a state of feeling, at once so potent and so evanescent, as to elude the cautious touch of analysis. It belongs, therefore, only to persons of superior genius, and by such alone must be attempted; since, like all superlative excellencies, it verges for ever on the brink of absurdity; and criticism has never yet been able to erect a sufficient barrier to defend its utmost limits. Like every other passion, it must be felt before it can be expressed; and the mind of the writer or the speaker must be well fortified with knowledge on the subject he is handling, and the judgment well exercised in the nice discriminations of taste, of feeling, and of decorum, before he ventures to indulge it in composition or in delivery, if he addresses himself to the enlightened or educated portions of the community, or he will be worse than disappointed of his object. In circles of a different description, however, it is evident that the mere semblance of enthusiasm, unaided by these preliminary qualifications, seldom fails of a very powerful effect: and, by this quality alone, bigotry and fanaticism frequently accomplish their end, and maintain absolute dominion over the minds of their ignorant votaries. It is therefore sufficiently obvious, that it is a quality the orator, if he be susceptible of it, should never fail to cherish; and if he be not susceptible of it, he is but a fragment of an orator. As for poetry, enthusiasm is admitted to be its very soul and essence. In the delivery of eloquence, or the recitation of poetry, genuine enthusiasm is expressed by a deep and powerful aspiration, by an increase of quantity in all the syllables principally produced by the prolongation and increase of the power of the voice on the liquids and liquifiable consonants; a restrained vehemence, which, without any of the disgusting effects of vociferation, spreads the undulations of sound through an extended circle. It is generally accompanied by a considerable dilatation of the nostrils, a protrusion of the eye-balls, and great tension and rigidity of the whole muscular system. Shakespeare, who felt its influence so frequently, has finely described its operation in the speech of Henry V. before Harfleur:

"Now set the teeth, and stretch the nostrils wide,  
Hold hard the breath, and bend up every spirit  
To its full height."

The whole speech is one of the finest effusions of enthusiasm.

fiatm ever penned, and requires in the reciter all the inspiration of that powerful feeling.

**ENTHUSIAST**, *Ενθουσιάζων*, a person possessed with enthusiasm. See **ENTHUSIASM**, **FANATIC**, &c.

The word is generally understood in an ill sense. It was applied by the ancients to a sect of heretics, called also Massalians and Euchites; who, as Theodoret expresses it, were denominated enthusiasts, because being possessed by the devil, they believed themselves divinely inspired. See **MASSALIANS** and **EUCHITES**.

Among us, enthusiast is sometimes of like import with fanatic, and is applied to the Quakers, and ancient Anabaptists, and modern prophets, from their pretences to extraordinary lights, revelations, visions, impulses, &c. from heaven.

**ENTHYMEME**, in *Logic* and *Rhetoric*, an argument consisting only of two propositions, an antecedent, and a consequent deduced from it.

The word is Greek, *ενθυμημα*, formed of the verb *ενθυμησθαι*, to think, conceive, a compound of *εν* and *θυμος*, mind.

Aristotle calls it the rhetorical or probable argument; the schools, the imperfect syllogism, in contradistinction to the perfect, which consists of three propositions, and is called the dialectical argument.

It must be observed, however, that the enthymeme is really a perfect syllogism in the mind, and only imperfect in the expression, because one of these premises is suppressed, as being sufficiently clear and obvious, and easily supplied by the understanding of those with whom we discourse.

Thus, in every right-lined triangle, the three angles are equal to two right ones; and consequently, they are so in an isosceles triangle, is an enthymeme; the proposition, that an isosceles triangle is a right-lined triangle being omitted, as being sufficiently known and granted.

The enthymeme is the most simple and elegant of all argumentations; being what a man, in arguing closely, commonly makes, without attending at all to the form. Thus, that verse remaining of Ovid's tragedy, entitled *Medea*, contains an enthymeme: "Servare potui, perdere an possum rogas:" "I was able to save you; consequently, to have destroyed you." All the beauty would have been lost, had all the propositions been expressed; the mind is displeased with a rehearsal of what is no ways necessary.

Sometimes, also, the two propositions of an enthymeme are both included in a single proposition, which Aristotle calls an enthymematical sentence, and gives this instance thereof: "Mortal, do not bear an immortal hatred." The whole enthymeme would be, "Thou art mortal; let not, therefore, thy hatred be immortal."

**ENTIER**, in the *Mange*, is used for a sort of refty horse, that refuses to turn, and is so far from following or observing the hand, that he resists it. If your horse is entier, and refuses to turn to what hand you will, provided he flies, or parts from the heels, you have a remedy. by putting the Newcastle on him; that is a cavesson, made after the duke of Newcastle's way.

The word is French, and is also used among them to denote a stone-horse.

This term, in its common acceptation, is applied to a horse that refuses to turn, and whose refusal proceeds from the awkwardness and stiffness of the body and limbs, and sometimes from malice and bad habits. In some cases, a hurt in his foot, leg, or shoulder, may be the cause of his refusing to turn to that side where he feels any pain. A hurt in his reins or haunches, a curb or spaving, which, by hindering him to bend and rest upon his hocks, may make

him guilty of this disobedience. These are evils which art can do little towards curing. The term entier, in its figurative sense, in which it is always to be understood in horsemanship, means a stiff horse, or one that is not suppled, and therefore refuses to turn, from the pain and difficulty which he finds in putting himself into a proper posture. Accordingly the Italians, from whom the terms of horsemanship are chiefly taken and adopted, or naturalized by other nations, figuratively call a stiff and undisciplined horse, a whole, entire, or unbroken horse; which, from the stiffness and tightness of his joints and muscles, is not able to bend himself, but in turning moves all of a piece, like a beam, or bar of iron; while the active and suppled horse, who can bend himself readily, and becomes part of the circle he describes in turning, may be said, like a chain, so to loosen and shift his limbs, as to break and divide himself, as it were, into parts; whence, perhaps, the term "horse-breaker," for one who forms the paces, and qualifies horses for being rode. Berenger's *History and Art of Horsemanship*, vol. ii.

**ENTIERTIE**, from the French *entier*, is used in our *Law-books*, in contradistinction to moiety, and denotes the whole. Thus a bond, damages, &c. are said to be entire, when they cannot be divided or apportioned.

**ENTIRE LEAF**, in *Systematic Botany*, *folium integerrimum*, a leaf whose edge is not cut or toothed; the term has no reference to *folium integrum*, an undivided leaf, which last is destitute of lobes or segments, without regard to its margin.

**ENTIRE Tenancy**, in *Law*, is contradistinguished to *several tenancy*, and signifies a sole possession in one man; whereas the other denotes a joint, or common one, in several. See **TENANT** and **JOINT-TENANT**.

**ENTIRE Arms**. See **ARMS**.

**ENTITATIVELY**, **ENTITATIVE**, implies an abstraction, or separation of all the circumstances, from a thing under consideration.

Thus, a thing is said to be taken or considered entitatively, or *secundum entitatem*, when considered nakedly and precisely, according to what it is in itself, without any thing extrinsic. *E. gr.* Peter entitatively taken, is Peter, as a thing, a substance, a man, &c. without any regard to his being a lord, a husband, learned, &c.

**ENTITY**, in the *School Philosophy*, a physical ens, or being, considered according to what it is in its natural capacity.

Some dealers in distinctions give us several kinds of entity.

Or, entity denotes the actual essence or existence of any thinking thing. See **ENS**.

**ENTLIBUCH**, in *Geography*, a village of Switzerland, in the canton of Lucern, the principal place of a bailliage, which extends from the Emme-thal in the canton of Bern to the bridge near Wertenstein, about 15 miles in length and 9 in its greatest breadth; and contains 11,000 persons. It is governed by a bailiff, who is always a senator of Lucern; he continues in office two years, and generally resides in that capital. The bailliage is divided into three districts; the upper, or Eschlismat, the middle, or Shuepfen, and the lower, or Entlibuch; each of which has its separate courts of justice, from which an appeal lies to Lucern. The valley of Entlibuch is watered by several rivulets, winding for some way between two ridges of well-wooded hills, and abounding in picturesque scenery. It contains several villages, of which the principal are Eschlismat, Shuepfen, and Entlibuch, which takes its name from the river Entle, and gives it to the whole district. The inhabitants chiefly follow

low agriculture; they rear large quantities of horned cattle, sheep, goats, and swine; they also make and export cheese in great abundance. The peasants of Entlibuch are much esteemed for their independent spirit, vigour, and strength; and are remarkable for keeness and vivacity, for great quickness in repartee, for a peculiarity of garb, and for many striking customs, which distinguish them from the natives of circumjacent districts. The valley of Entlibuch may be considered as one of those parts which unite with the mild and cultivated the wild and rugged scenery of Switzerland; its acclivities gradually ascend and terminate in mount Pilate, whose barren top is seen towering above the fertile and well-wooded hills. In the 13th century, Entlibuch was subject to the counts of Wolhausen, and came by purchase, in 1299, to the emperor Albert. In the following century it was held as a fief from the house of Austria by several successive counts; till the nation, grievously oppressed by Peter of Torrenberg in 1386, threw itself under the protection of Lucern. That republic continued to possess Entlibuch, as a feudal tenure under the house of Austria, till the year 1405; when the archduke Frederic renounced all the rights of sovereignty. For above a century and a half, the inhabitants, inflamed with a desire of independence, and excited by the example of the popular cantons, frequently rose in arms, and attempted to establish a democracy, but without success. Their last insurrection broke out in 1653; since which time they have continued in a state of perfect tranquillity under the administration of Lucern, enjoying, with contentment, the privileges with which they are endowed. The peasants of Entlibuch were distinguished by their attachment to the government, and by their decided opposition to French principles, during the late revolution. Coxe's Travels in Switzerland, vol. i.

ENTOGANUM, in *Botany*, Gærtn. t. 68. See MELICOPE.

ENTOMOLITHUS, in *Natural History and Mineralogy*, is the name of a genus of the animal order of remains (*reliquia*, or *relicts*) of a former race of beings, which inhabited the earth or its waters, and includes the different kinds of insects found in a fossil state. According to Mr. William Martin (*Outlines of the Knowledge of extraneous Fossils*, p. 191), the essential characters, or diagnostics of the permanent species in this genus, are to be sought, in "the upper external covering of the thorax, united to that of the abdomen;" the temporary species of this genus are to comprise the detached head, thorax, abdomen, limbs, &c. of fossil animals, resembling the recent species of insects. See RELIQUIA.

ENTOMOLOGY, the science of insects, or, as literally rendered from the Greek, a *discourse on insects*; the term by which the study of these animated beings is expressed.

Insect, from *insectum*, Latin, is of later origin than *έντομα*, the term made use of by Aristotle, who flourished in the fifth century, before the Christian era, and was invented much earlier than the time of that celebrated philosopher. Aristotle defines it to signify an animal which by incisions is nearly severed into two or more parts, and the Latins, long before the time of Pliny, (who lived in the reign of Titus,) employed the word *insectum*, from *insecor*, which precisely bears the same interpretation.

The insect race constitutes the most considerable portion of the whole class of organized bodies possessing the vital principle of life. The number of aquatic beings concealed from our research in the depths of the ocean cannot be within the reach of human estimate; it is to the terrestrial tribes, or those which inhabit the surface of our globe, that we alone allude; and the entire amount of these, including every order,

is confessedly inferior in point of number to the single class of insects. Among the larger animals the discovery of a few new species, or of individuals not correctly ascertained before, is esteemed of consequence; but so extensive are the limits of entomology, that the discovery of a multitude of insects under the same circumstances fail to excite astonishment, though it may awaken curiosity; and, indeed, its frequency seems calculated to confirm the commonly received opinion, that the insect race, in the diversity of species, much more in the number of its individuals, must be almost boundless.

In this view the science of entomology becomes one of the most important that can engage the mind of the natural philosopher. It is the difficulty of discriminating the particular affinities and characters of these beings, arising from their amazing number and variety of form, in addition to their minuteness, that more strongly enforces their claim to his consideration. The naturalist who neglects the study of insects, cannot deserve our respect as a general observer of nature. His views are partial; his enquiries circumscribed; he regards only an inconsiderable portion of animated nature; and his remarks are confined chiefly to those which, from their magnitude and distinctness of character, present the least obstacle to investigation.

The study of every class of animals is indisputably attended with peculiar advantages; and in none is this assurance more clearly manifested than in the tribe of insects. In the mazy labyrinth of entomology, the naturalist will find abundant scope for the exercise of his zeal and application, and in the course of his enquiries the full exertion of his penetration will be oftentimes required to the ascertainment of truth. The amazing number of species it embraces; their forms so extraordinary; so infinitely varied; and yet so gradually approximating through an endless series of transitions from one species to another; the diversity of structure observable in their antennæ, their limbs, bodies, wings, and every other particular which constitute the essential differences of their orders, genera, and species; added to the surprising changes in form which the generality of insects undergo at stated periods of their life:—these are circumstances which contribute to render them objects of the most curious speculation to the naturalist, and we shall venture to affirm, that it is from a knowledge of these, their characters, transitions, metamorphosis, and the various modes of life these little beings are destined to pursue, that he will obtain a more intimate acquaintance with the great laws of animated nature, than can possibly be derived from the contemplation of any other tribe in the creation.

As insects surpass all other animals in their number, variety, and singularity, so also it is a natural inference that they must deserve the greatest share of attention. The history of these creatures abound with the most valuable information in a philosophic view, and strongly recommend the study to the attention of every curious observer. Entomology possesses many other attractions, some at least of which have not been well considered. The only one to which we shall particularly advert at this moment, is the beauty of insects in general, a point on which there can be no difference of opinion. These little creatures are rendered engaging from the gaiety of their natural hues: from combining oftentimes with the most graceful forms a display of colouring very far excelling in splendour, vivacity, delicacy, and harmony of disposition, that bestowed by the hand of nature on her other works. One defect in their appearance must be nevertheless conceded; and this may be regarded in point of beauty as a material deficiency indeed: they are not always so considerable in magnitude, as to become, even with these embel-

## ENTOMOLOGY.

ishments, strikingly attractive: were they only equal in size to the minor tribes of birds and animals, their unrivalled elegance would certainly render them objects of high esteem in the general opinion of mankind.

But the diminitiveness of insects ought to operate in a contrary manner on the mind of the philosopher. While this cause opposes the greater difficulty to the study, it should more strongly incite investigation. This we are aware is not always considered as an inducement, and the diminitiveness of these creatures has been sometimes urged as a reason that they do not merit the attention bestowed upon them. However injudicious this opinion ought in candour to be conceived, it has obtained the countenance of many; and among the number, of some men at least who, from their superiority of talent, might be deemed incapable of advancing such an argument against the study of any department of natural science. Thus the ingenious Buffon, whose attention, as is well known, was restricted to the larger tribes of animals, intimates its inferiority in language sufficiently pointed. "Who (says this lively author) gives us the grandest and most magnificent ideas of the creator of the universe? he who represents him in the plenitude of his power, directing the formation of suns and of planets, and guiding the revolutions of worlds, or he who discovers him busied in regulating the economy of a hive of bees, or deeply engaged in folding the wings of a beetle?"

How different is this from the sentiments expressed by other philosophers, who, with more enlarged and liberal views, have held every branch of natural science in its proper estimation! There are many who even assign a higher degree of perfection to the insect race than to other classes of animals. We learn the opinion of Pliny from his own words. "In his tam parvis tamque fere nullis quæ ratio! quanta vis! quam inextricabilis perfectio!" Boyle declares, that for his own part his wonder was more excited by the contemplation of a mite than an elephant; and Reaumur speaks more decidedly to the same effect, in language worthy of repetition. Pourquoi, (says this author,) craignons-nous de trop louer les ouvrages de l'Être Suprême? Une machine nous paroît d'autant plus admirable, et elle fait chez nous d'autant plus d'honneur à son inventeur, que, quoiqu'aussi simple qu'il est possible par rapport à la fin à laquelle elle est destinée, il entre dans sa composition un plus grand nombre de parties, et de parties très-différentes entre elles. Nous avons une grande idée du génie de l'ouvrier qui a su réunir et fait concourir à la même fin, autant de parties différentes et nécessaires. Celui qui a fait, les machines animées que nous appelons des insectes, n'a assurément fait entrer dans leur composition que les parties qui devoient y être. Combien, malgré leur petitesse, ces machines nous doivent-elles paroître plus admirables que celle des grands animaux, s'il est certain qu'il entre dans la composition de leur corps beaucoup plus de parties qu'il n'en entre dans celle des corps énormes des éléphants et des baleines! Pour faire paroître au jour un papillon, une mouche, un scarabée, en un mot, tous les insectes, qui ont à subir des transformations, il a fallu au moins faire l'équivalent de deux animaux, faire une chenille dans laquelle le papillon prit tout son accroissement, faire des larves dans lesquelles la mouche et la scarabée pussent croître". Swammerdam is impressed with the same idea. "After an attentive examination (says this writer) of the nature and anatomy of the smallest as well as the largest animals, I cannot help allowing the least an equal or perhaps a superior degree of dignity to the former. If, while we dissect with care the larger animals, we are filled with wonder at the elegant disposition of their parts, to what an height is our astonishment raised, when we discover

all these parts arranged in the least, in the same regular manner! Notwithstanding the smallness of ants, nothing prevents us from preferring them to the larger animals, if we consider either their unwearied diligence, their wonderful strength, or their inimitable propensity to labour."

Another objection, for we shall not term it argument, has been advanced against this study, the validity of which cannot be so thoroughly examined in this place as we could wish; it has been stated, that because insects furnish few of the articles of life they deserve no consideration. This is the language of ignorance, and such as we could easily shew to be of the most futile kind. The study of these creatures is as replete with utility; and the knowledge of them as essential to the benefit of mankind, as most other branches of scientific pursuit; nor shall we scruple to aver, that in this particular respect entomology claims a decided superiority over every other department of zoology. But the fact is evident, that the importance of this science, at least in Britain, has never been duly appreciated, and this arises from the most obvious of all causes, that it has not been sufficiently explained.

Insects may properly be divided into two kinds, those which are either directly or remotely beneficial, or injurious to the purposes of mankind. Many insects, it is true, do not seem to affect us in any manner; but appearances in this respect, let it be observed, are not always to be relied upon. Others, and the number of those is very great, most assuredly fall within the denomination of one or other, and even both the first mentioned kinds, and for this reason ought surely to demand our attention. In the ordinary concerns of life it is deemed of as much, if not greater consequence, to know our enemies, and ascertain the powers of annoyance they possess, as it is to learn what benefit we may be able to derive from our friends: let us apply this plain and rational argument to the study of insects, and we think it will appear equally consistent, when we assert that it is as important to know those which are injurious to our interests, as those which contribute to our advantage. When we are convinced in what respects particular insects have the means of doing us injury, we may guard against their attacks, or apply a remedy to the evil, and if we neglect to obtain those services from the beneficial kinds which they are designed by nature to afford us, it can be no proof of our wisdom.

Left, to the superficial observer, our allusion to the utility of insects should appear theoretical, while the noxious propensities of others may be too fully experienced in the affairs of agriculture, horticulture, and throughout the various branches of domestic economy, to admit of doubt, we shall be more explicit in this observation. The ravages of insects upon vegetation are detrimental to us; but let it be remembered also, that even in these depredations they sometimes repay the injury they commit. The locust itself, the most destructive of all insects, and whose myriads spread desolation through the vegetable world, are not unproductive of advantage, except on some very extraordinary occasions, when their multiplication exceeds all bounds. At other times they deprive mankind of a certain portion of his vegetable food, and, in return, their bodies afford him animal nutriment of a wholesome and palatable kind, and in infinitely greater abundance. The various sorts of locusts are the common food on which the inhabitants of many parts of the world, at particular seasons, chiefly subsist. The honey of bees, both of the wild and domestic kinds, constitute another primary article of food in many warm countries, in the present as in ancient times. The hydromel of the Russians, an excellent and delicious drink, is prepared

## ENTOMOLOGY.

pared from honey, as our beverage is from malt. The various tribes of silk worms, (for of this kind there are several species,) furnish materials for the raiment universally worn by all ranks in the eastern parts of the world, and hence in those countries the silky produce of these industrious little beings is of as much real consequence to them, as the fleecy coat of the sheep is to us the staple article of clothing; as an object of traffic, silk is one of the utmost importance in China and Tartary, and in those parts the paper in common use is also manufactured from the refuse of the same material. The extensive use of wax in all ages is well known; but it is less generally understood that wax is not the produce of the bee alone; the wax insect of China is a very different creature, a species of cicada in the larva state, and which, with the addition of a vegetable oil, forms the mixture of which the candles of that country consist. (Donov. Inf. China.) Certain insects are employed with success in medicine, and a further number might be applied to the same purpose; many others might be also rendered useful in the arts, and lastly, we need only advert to the valuable properties of the different species of cochineal in the art of dyeing, to prove the absurdity of an opinion very generally prevalent among us, that insects are a race of creatures too insignificant to deserve the notice of mankind!

But, were all these benefits unknown; and allowing that the study of insects did not seem to be productive of any substantial advantages, how absurd would it still be to treat such a fair and extensive portion of the creation with neglect. The objection that they are in no manner conducive to our interests, even if founded in truth, would be no evidence of the frivolity of the science itself, unless we are to conclude that the only enquiries which merit the rational attention of mankind, are those which tend to the gratification of selfishness. If this be admitted as a plausible objection, how many objects of philosophical investigation must be rejected as frivolous!

From the earliest period of which any authentic records remain, this race of animals has obtained the attention of every civilized age. The study of these creatures has not assuredly been cultivated with equal ardour at all times, nor has every country produced entomologists of considerable talent. It will be sufficient to shew, that the science itself has never remained in utter neglect, from the remotest period in which the light of natural knowledge dawned upon the intellectual horizon of man. The experience of all ages distinctly proves the charge of frivolity to be inapplicable to this study: many advantages, besides those above enumerated, have been, and continue still to be, derived from this source; and it is furthermore deserving of our observation, that among the number of its votaries in distant periods of the world, we trace the names of the most distinguished characters that adorn the page of history. Perhaps we are at this moment addressing, among the circle of our readers, some at least who, nurtured in habitual indifference towards the subject under discussion, have incautiously fallen into the error of considering it as a trivial pursuit. But we are not without expectation, that even the slight observations which the limits of our paper allow, will direct their attention with more liberality towards this subject, and we shall not hesitate to think in the result of this, they will easily conceive much stronger arguments in its favour than we have adduced. To the idle, or the thoughtless confirmed in prejudice, it would be in vain to offer any reason in its behalf, and to those we shall observe with brevity, that whatever opinion they may be inclined to entertain of its frivolity, the science of entomology will be found in every civilized age and country to have engaged the study of men endowed with talents as

splendid and judgment as refined, as the most exalted for ability among those who affect to treat it unworthily.

These observations opportunely introduce to our consideration a review of those writings which have contributed to enlighten the paths of science in this particular study. The number of these; the value and interest which must unavoidably attach to their contents; and the names of those illustrious characters by whom many of them were produced, will fully sanction, it is presumed, the assurances before advanced. These works, even in point of number alone, we have no doubt will be found infinitely more considerable than most imagine; and this circumstance, independently of any other, tends to prove that we are not singular in our commendation of entomology either as an instructive or useful science; as morally, and intellectually beneficial; for those who write on any subject like the present, must be impressed with some idea of its importance, and these opinions may be collected uniformly from the labours of writers on the study of insects.

As we deem this subject of consequence, it is our decided wish, even in the cursory view to which our limits are restricted, not to omit the mention of any work, however slight, that has been productive of material information. Our strictures, it will be understood, are confined to those we have had sufficient opportunity to consult with some attention; for this we consider due, in candour, to the respective writers whose labours are devoted to the elucidation of science. Sometimes we may be inclined to express ourselves with warmth in favour of merit, neglected, forgotten, mouldering in decay, or which, from latent motives, has never been sufficiently appreciated by later authors. If we err in this, let it be remembered, that in the truth of criticism we oftentimes evince more judgment in bestowing praise, than awarding censure. But we wish it to be explicitly understood, that we do not consider it within our province, at present, to enter at large upon a critical analysis of the multitude of writings before us. Our only object is to point out the existence of the most valuable works that are extant within our own knowledge, describing at the same time the leading intention of their authors respectively: the collateral remarks can be only those immediately incidental to such investigation. The several works enumerated will be adverted to, as nearly as possible, according to the order in which they appeared before the world; and hence our review, however cursory, will be attended with this peculiar advantage, that it will serve to point out the progressive improvements the science has derived from the labours of each succeeding author, in a more perspicuous form than could perhaps be accomplished in any other manner. It will also by this means be found calculated to afford the general reader

### *An Historical view of the Rise, Progress, and Present State of Entomology.*

The destruction of the great public libraries of antiquity has for ever deprived us of the means of ascertaining precisely to what state of perfection this branch of science had attained, till within about two thousand years of the present period. Of those times a few scanty memorials alone remain, sufficient, however, to testify that the study of insects had then made some progress, and was held in estimation. Whatever may be our ideas with regard to still earlier times, it would be needless to obtrude them in this place. We shall observe only, that some books must have been written on the subject before the existence of those which have descended down to us: the reputation of such writings is preserved, and in certain instances the names of authors recorded in the very earliest of those works at present extant,

## ENTOMOLOGY.

which clearly demonstrates the truth of this opinion. Time has not spared the labours of any writer on this subject of more remote date than the third, fourth, and fifth century before the Christian era, and the amount of those which have survived is small indeed; but inconsiderable as they are, in point of number, we may, notwithstanding, collect from them that the study of insects, in those days, held a rank among the liberal pursuits of their philosophers.

We may, indeed, proceed still farther in this retrospect, if the sacred writings of the Hebrews be considered. These abound with passages relating to particular kinds of insects, as the locust, the caterpillar, flies, and vermin. Moses, the earliest of the inspired writers, had probably acquired some knowledge of this subject, in common with the other sciences, from the sages of Egypt; and among the books of Solomon, now lost to the world, it is recorded that he treated on insects, or "creeping things."

Hippocrates flourished in the 80th Olympiad, or fifth century before the Christian era; he wrote on insects, as we are told by Pliny, in whose time some remains of the entomological observations of this celebrated character were probably extant. The writings of the early Greek and Latin writers, quoted by Pliny, afford extracts from this production of his labour.

The succeeding age gave birth to that distinguished natural historian and philosopher Aristotle: the production of whose labour, his history of animals, is worthy of the patronage bestowed on its author by the conqueror of the universe. No one can impartially peruse this inestimable treasure of antiquity without confessing the intimate knowledge its writer must have possessed of the great arcana of nature.

This work of Aristotle is rather of an elementary kind, embracing a general, wide, and comprehensive view of the animated creation, and does not, except on particular occasions, descend to the description of individuals or species. The insect tribe is treated under different points of comparison and view in several parts of the work. In the seventh chapter of his first book, he informs us, that the name *ἕντομα* is generic, or that of a family, and that they constitute one of his four orders of exsanguineous animals, and points out with great accuracy in what respect they differ from the mollusca, crustacea, and testacea, the other three families of this class of animals. By exsanguineous he means only that they have no red blood, for he speaks generally to their bodies being retained in a state of moisture by other fluids. The first chapter of the fourth book affords a definition of the essential character of insects, which consists in the incisions or cuts either on the back or belly, and sometimes on both, by which their bodies appear to be almost divided into two or more parts. But that portion of his work which is more particularly devoted to insects, is entitled *Περὶ τῶν ἕκτο; καὶ ῥίαν τῶν ἐν τούτοις*. In this he more fully describes insects to consist of three parts, the head, trunk, and belly or abdomen; the second part, or trunk, is denominated an intermediate portion, corresponding with the back and breast in other animals; and he also mentions as a character of insects that they are furnished with feet.

The subsequent passages describe different genera, or, as termed, tribes of insects, in which he treats of those which fly and those which walk. Among those furnished with wings, he speaks of some having these parts entirely naked, and others that have them protected by a sheath, or covering, as in the beetle kind: as he furthermore states, that in some beetles these sheaths divide or open when the insect flies, and that in others they are inseparably united. The insects which have naked wings, he observes, possess either four, as in the bee, or two, like the musca or common fly. Some of these

with four naked wings have stings at the end of the body, while beetles, and insects with two naked wings, are destitute of this apparatus; but some of the latter, he tells us, have a proboscis or instrument at the mouth, by means of which they draw blood from other animals. The horns before the eyes (by which he means the antennæ) attract his observation, and those of the papiliones and grylli are particularly described. In his remarks on the different structure of the feet, those formed for leaping are exemplified by those of the locust, and are compared to the posterior feet of springing animals. The humming noise of certain insects in flight, the cruce, and various other circumstances relative to this class of animated beings, have interested the philosopher in this chapter.

The attentive entomologist will feel deeply sensible of the accuracy of every expression, thought, and sentiment, implied in the above-mentioned passages. He will be surprised at their consistency. Their accordance with the entomological definitions of the best modern systematists will excite farther comparison; and in the result of this inquiry it must be obvious, that with the acquired knowledge of two thousand years since his time, so far as he does proceed, we cannot materially amend his observations. This will be admitted; and at the same time we believe even a cursory perusal of the whole work will serve to shew, that whatever might be the merits of Aristotle, and we allow them to be transcendent, these writings evince too much acquaintance with the science of nature, to be the produce of any individual genius shining with unborrowed light. When we reflect upon the slow and gradual progress with which all human knowledge is developed, we are really convinced that the science of nature must have made some considerable advancements before his time; and that he has derived many eminent advantages from consulting the works of more ancient naturalists: men whose original labours have been lost to posterity for ages, and the only traces of which at present extant are to be found embodied in his pages.

Ælian, in his work on animals, ΠΕΡΙ ΖΩΩΝ ΙΔΙΟΤΗΤΟΣ, appropriates several detached chapters to particular kinds of insects, without entering in a methodical manner into the history of the tribe. Those he does include are described with attention: as, for instance, the scorpions, *Σκορπίων*; ants, *Μυρμηκῶν*; spiders, *Ἄραχνα*; crickets, *Τετρίγων*; the generation of wasps, *Περί τῆς Σφηκῶν γενέσεως*; of cantharides, *τῶν καλέων Κανθαριδῶν*, &c.

The Greek poet Phile, called also, from his superior knowledge of natural history, "Phile Sapientissimi," introduces some pleasing poetical effusions relative to insects among his poems on animals. The manners of the cicada, and the bees, *τετρίγων*, and *μελισσῶν*, are very prettily described in verse by this writer. He entertains the same idea as Ælian, that the cicada, by which he means the cricket, (not the insect named cicada by Linnæus,) lived on dew; and that the female was mute, while the male "enchanted the grove with the harmony of song." He speaks also of the lampyris, and various other insects. The beautiful ode of Anacreon to the cicada is familiar to many.

Among the Greek writers who immediately, or within a few centuries after, followed Aristotle in treating upon insects, were Democritus, Neoptolemus, Aristomachus, Philistus, Nicander, Meneceates, Dionysius Mago, Empedocles, Callimachus, Attalus, Apollodorus, Eriphilus, Erasistratus, Asclepius, Themiso, Posidonius the stoic, Meander of Priene, Euphronius of Athens, and Meander of Heraclea, Theophrastus, and Hesodius. These were authors after the time of Aristotle, and preceding or contemporary with Pliny. The Latin writers, during the

same interval, were also numerous, and appear to have been influenced to pursue this study in imitation of the Greeks, or were insensibly led into it from attending to the culture of bees. The most eminent among the latter were M. Varro, Hyginus, Scropha, Sarcana, Celsus Cornelius, Æmilius Macer, Virgil, Columella, Julius Aquila, Tarquilius, Umbritius, Cato Censorius, Domitius, Calvius, Trogus, Melissus, Favonius, Fabianus, Mutianus, Nigidius, Manilius, and Opius. The cultivation of bees was attended to in those times with the most enthusiastic ardour, and their history detailed by many eminent writers. We are told that Aristamachus of Soli wrote upon this subject, from the result of sixty years experience; and that Philiscus the Thasian acquired the name of Agrius, from having employed his whole life in forests and deserts, attending to these insects. The culture of silk-worms was another favourite object with the ancients, as we learn from Pliny, who relates that in his days garments of silk were greatly admired by the fair sex, because, from the delicacy of its texture, it displayed the beauty of their persons almost as distinctly as though they were naked.

The eleventh book of Pliny treats of insects, as the most subtle of all animals in nature. He speaks of those which fly; some with naked wings, and others with wings protected by a covering, as Aristotle had previously observed. The bees, wasps, hornets, spiders, grasshoppers, locusts, ants, &c. are among the number of insects described by this writer.

From the time of Pliny till the overthrow of the Roman empire, a period of several centuries, the science of insects seems to have made some progress, though to what extent we may probably never learn. The names of writers in those times, and some few scattered memorials of their labours, are to be found recorded in the voluminous works of authors that appeared at the revival of learning in the sixteenth and following century. The number of these could not have been very inconsiderable: among the principal of them were Ætius, Paulus Ægineta, Alexander, Trallian, and Oribasius.

The last-mentioned authors lived between the fourth and seventh century. After this time, through the dark ages, while ignorance in every science prevailed nearly over the whole world, this study might have been little attended to. But we are not to conclude that even during this time it was utterly neglected. Learning had then taken a retrograde course from Greece and Rome towards those eastern regions, from whence they had originally emanated; and the sciences, during this interval, were cultivated with some success in Arabia. The advancement made by the Arabians in the study of botany, between the ninth and twelfth century, is known to have been rather considerable. Among the entomologists of those ages we recognize some of those Arabian botanists; several of whom were distinguished for their acquaintance with plants, as Rhazes, Avicenna, Avenzoar, and Averrhoes, each of whom wrote on insects.

From the twelfth to the fifteenth century, a darker period than the preceding, there are few writers on this subject. The principal of those, at least within our knowledge, during this period, are Myreplus, Hildegardis, Platerus, Arnoldus de Villa Nova, and Petrus Crescentienus. There are a few others, but they are too obscure to deserve mention.

Some part of the general zoological work of Albertus Magnus, "De Animalibus," &c. relates to insects. Its author was bishop of Ratisbon, and died in 1280; but his work, which is written in the Latin tongue, and was printed at Venice, did not appear till the year 1519.

In 1549, the work of Agricola, entitled, "De Animalibus subterraneis," made its appearance; and in this we find one of the earliest systematic arrangements of insects extant. This author reduces all insects to three principal classes, namely, \*those which walk, \*\*those which fly, and \*\*\*those which swim; and under each class describes a number of species.

About the middle of the same century, Edward Wotton, a doctor of medicine in London, published "De Differentiis Animalium;" a work relating, among other tribes of animals, to that of insects, a science in which its author excelled. This work is in folio, and bears date 1552; from which it must have appeared three years before the author's death, which happened in 1555.

The work of Rondeletius of Montpellier, "Libri de Piscibus Marinis," published in 1555, or rather earlier, treats, as the title intimates, on fishes, and other aquatic animals; to which, however, it is not entirely confined; for he also speaks of insects, and even accompanies some of his descriptions of these insects with figures cut on wood. Lesser mentions that in the library of the Jesuits at Ratisbon, there is a copy of this work in two volumes; on the margins of the leaves of which are large notes, said to be in the hand-writing of Gesner. Whether these notes have in any manner appeared before the public we know not: the circumstance is repeated only for the purpose of inquiry. If Lesser afforded any intimation of the nature of those notes, we might ascertain whether they are the same with the observations of Gesner on Rondeletius, in his "Historia Animalium," an edition of which we suspect was printed soon after the work of Rondeletius appeared.

Conrad Gesner, esteemed the most diligent inquirer into nature which his age produced, and who, in reward for his assiduity, obtained the title of the German Pliny, has treated slightly on insects in that part of his work which relates to the nature of serpents, "De Serpentina Natura," &c. printed in 1587. His discourse is chiefly concerning the scorpion tribe. Some tracts of this author appear to have been published so late as 1620; neither of these, however, are on the subject of entomology.

A far more voluminous work than either of the foregoing was produced by the industrious and learned Aldrovandus, in 1602; a folio volume of several hundred pages, with the title "De Animalibus Insectis," and forming part of his grand work on animals. Aldrovandus has not escaped censure. In the "Amœnitates Academicæ," Forstal considers him as an indefatigable compiler, celebrated for the number of his works, but who thought he had acquitted himself in collecting together the undigested observations of the ancients. We cannot avoid expressing other sentiments; and notwithstanding that he has fallen into many errors of his predecessors, this work entitles his memory to respect. Aldrovandus was not merely a compiler; he availed himself of the labours of former writers, and in this respect with less servility, and certainly with more candour, than many who advance this objection against him: for he generally refers to his authorities. Aldrovandus was professor of medicine in the university of Bologna, and, according to his biographers, the study of insects was his favourite object. In this pursuit he expended large sums of money, travelling for information, and in the employment of artists; as he was unfortunately, like some other eminent naturalists, himself deficient in the talent of drawing. During the space of thirty years, he paid two hundred florins annually to a painter, solely occupied in the delineation of insects for him. From the fatigue of his researches, this indefatigable naturalist was unhappily deprived of sight in his old age.

## ENTOMOLOGY.

In his classification of insects, he divided all these animals into two primary orders, the terrestrial and the aquatic; the first called *favica*, the other *non-favica*. These two classes are subdivided into many orders; the characters of which are determined by the number, nature, and position of the wings and feet.

The representations of the insect tribes, from their inferiority of size, added to the general minuteness of their characters, are rather more rudely expressed in the work of Aldrovandus, than the figures of the larger animals, which these volumes contain. A defect of this kind is less excusable, because from the liberality of Aldrovandus towards his artist it might not be expected; and furthermore, because about that period a better taste, and a desire for more expensive embellishments in works of this description, began to prevail. The graphic art, or engraving on copper, though scarcely emerged from infancy, was now introduced in aid of this science, in preference to cuts on wood, and with no small success, as we observe in the works of Hoefnagle, Hollar, and others of that period, whose labours are well known. Those embellishments, though greatly admired in their time, were, however, too costly to be introduced into works of the ordinary kind; they were confined to the more expensive productions, and, indeed, almost exclusively to those produced by artists themselves; for we seldom meet with them in any work of which the artist is not also the author. The best book of that period in our own country, for such we consider Mouffet's "*Insectorum Theatrum*," affords only cuts on wood, an instance sufficiently corroborative, as this work was printed in 1634. Even for the space of nearly a century after this, copperplate engravings were sparingly introduced. The learned Lister, in his edition of the works of Geodartius, so lately as 1682, laments the great expence of engravings, at the same time that he expresses his conviction that they are indispensable in works of this kind. "I have taken great care of the designs," says this writer, "in transferring them upon copper-plates, which I dare promise are exquisitely performed by the best of our English artists, which was at my expence; and the booksellers were not willing to reimburse me."—"And upon this occasion I must needs say, that natural history is much injured, through the little encouragement which is given to the artist, whose noble performances can never be enough rewarded; being not only necessary, but the very beauty and life of this kind of learning." But, to resume the course of our subject in historic order, the next work immediately in succession to Aldrovandus is that of Wolfgang Frenzius, published in 1612, and called "*Historia Animalium Sacra*," a valuable work, as containing much original observation. After the manner of Agricola, he distributes all insects into three classes, which he names *aërea*, *aquatica*, and *terrea et reptantia*. A small octavo, printed three years after, though a slight production, should be mentioned in this place; it is a treatise on ants, a pamphlet of about one hundred pages, and is written in Latin; the title "*De formica*," &c. by Jeremiah Wilde. The work of Fabius Columna, "*Aquatilium et Terrestrium aliquot Animalium Observationes*," printed at Rome in 1616, relates also, in some degree, to insects; and finally, in point of precedence to Hoefnagle, we have to notice another, a work of some moment, that appeared soon after, from the pen of Archibald Simpson: this was published in North Britain, and from the motives of the author and singularity of its contents claims explicit mention. From the title of this book, which is sufficiently explanatory, it will be perceived that entomology was only a remote object in the mind of the writer. The work de-

rives its greatest share of interest, in our present view; from being one of the first publications connected with the study of insects printed in Britain. This book, which is in quarto, was printed at Edinburgh in the year 1622, and bears the following title: "*Hieroglyphica Animalium terrestrium, volatilium, natatilium, reptilium, insectorum, vegetivorum, metallorum, lapidum, &c. quæ in Scripturis Sacris inveniuntur et pluriorum aliorum, cum eorum interpretationibus.*"

At length our enquiry arrives at that particular period when the painting of insects was esteemed suitable and worthy of the pencil of the most skilful artists of the age, the painters retained with magnificent salaries in the courts of princes, and in the most polished states of Europe. Under the fostering influence of such patronage, it ought not to excite surprise that some advancement was made in this branch of the art. For our own part, we are not impressed with any very high opinion of the talents evinced in depicting these pleasing objects, at least by some of the artists thus employed. With such inducements for the exertion of genius, and with the reward and credit naturally attached to their productions, they ought certainly to have succeeded better. But though the arts derived no very material advancement from their attention to this subject, to the cause of science their assiduities were productive of infinite benefit. The cultivation of exotic plants, which about that time began to be held in proper estimation, afforded an ample field to those artists whose labours were dedicated to the task of portraying these pleasing objects. Their great forte prevailed in painting flowers, and though insects offered for many charms of attraction, they appear at first to have been only introduced occasionally, and as secondary objects, to their pictures. These embellishments were attended with success in proportion to their fidelity, force, and truth. In a state of nature these lively creatures are constantly seen sporting about the unfolding blossoms of the vegetable creation in search of their nectareous sustenance, and their introduction could not fail to infuse a spirit of ideal animation into their best performances. Hence it seems, that insects were afterwards represented in their compositions with a less sparing hand; and, in the course of time, became with many artists the principal, instead of secondary object of imitation. Thus also, from casual observers, those artists were progressively led to a more intimate acquaintance with these creatures, and to an inquiry into their history, the novelty of which may be perceived to have amply gratified their curiosity, and rewarded their application. Their example fortunately inspired a congenial taste among their patrons, and hence, in the space of a few years, a new and more propitious era seemed to dawn upon the science of insects. The study was by this means promoted, and rendered an object of attention among the higher orders connected with the most enlightened courts of Europe; as for instance, that of France, the imperial court of Germany, and those of the princes of the empire.

An observation of the celebrated Jussieu in the beginning of the last century is altogether applicable to this investigation. "The arts and sciences," says this writer, "owe their perfection to circumstances which may appear the effect of chance," and the truth of this remark is completely verified in this particular instance; for, it must be recollected that the art of embroidery, a mechanical process, and which in our days is superseded by the more dignified production of the pencil, is that which called forth the talents of the painter to the delineation of natural objects in the age adverted to. It was to the improvement of embroidery that his merits were at first subservient; or at all events to a peculiar train of cir-

## ENTOMOLOGY.

circumstances arising originally from this cause, that we are to ascribe the progress made in this branch of the profession, from the close of the sixteenth till the middle of the succeeding century. About the reign of Henry IV. and Lewis XIII. of France, embroidery was in the zenith of fashion, for the decoration of magnificent furniture, and drawings of the most beautiful plants were made expressly for the embroiderer's imitation. The obligation which botany lies under to this cause is well known, and that of entomology during the same period, if attentively considered, will be found no less conspicuous.

The painters eminent for their abilities in this line, were Hoefnagle, Robert, Aubriet, De Bry, Vallet, and Robin. There were others to whom we shall advert more particularly afterwards. In order to demonstrate the benefit which botany derived from the labours of such artists, it need only be mentioned, that the celebrated Tournefort founded and arranged his system of plants upon the drawings made by Robert and Aubriet for the royal library of France. The other artists alluded to were still more conversant with the science of insects than the former, and their labours of their pen have contributed, in unison with their pencil, to promote this species of knowledge. Some especially were very successful in this respect.

Merian, Admiral, Schwertz, and Goedart, and also our own countryman Albin, were among the number of those most eminent for their acquaintance with the history of insects; and, were this list to be augmented with the names of other artists of somewhat later date, who have likewise distinguished themselves in the same manner, the result would testify that entomology, like many other branches of natural history, is greatly indebted for its advancement to this class of authors. It is from the works of the artist, or of those who by their application have rendered themselves competent to delineate the objects they describe, that the most valuable information has been obtained. The works of Rösel will sufficiently testify the truth of this observation, but were any other confirmation necessary, we would advert to Lyonet, who, though not an artist by profession, felt proudly conscious of his superiority as a naturalist, because from perseverance he had acquired the talents of an artist. Are they not the imitative labours of this class that furnish ample materials for the productions of those who are mere describers: writers, who oftentimes like hornets enter the hives of industry, and plunder without molestation?

The work of Hoefnagle, a thin volume in 4to. was published in 1630, under the title of "*Diversæ Insectorum volatiliū icones ad vivum depictæ per D. J. Hoefnagle, typifque mandatæ a Nicolao Joannis Vifcher.*"

The plates altogether contain figures to the amount of three hundred and twenty-six. The execution of these acquired the artist no small share of celebrity, yet it must be acknowledged that they are not invariably deserving of approbation; some at least are very indifferent. Hoefnagle does not adopt any particular mode of arrangement, and he contented himself with representing the insects in the states in which chance presented them, without always following them through their progressive changes.

Only four years elapsed after this volume of Hoefnagle's plates were brought forward, before another production of infinitely greater consequence as a work of science appeared in our own capital, namely, the entomological work of Thomas Moufet. This, as it professes to be, is an improvement on the work of Dr. Wotton, begun in the year 1550, about five years before his death: it was continued by Conrad Gesner, was afterwards enriched, as it is expressed by Thomas Penny, and at length assumed the improved form

in which it was published in 1634, from the hands of Moufet. This last mentioned editor revised the order of its arrangement, corrected and enlarged the descriptive matter, and embellished its pages with nearly five hundred wood-cuts, the greater portion of which, though rudely executed, are not destitute of merit. The work is intitled "*Insectorum five minimorum animalium theatrum: olim ab Edoardo Wottono, Conrado Gesnero, Thomaque Pennio inchoatum: tandem Tho. Moufet Londinatis operâ sumptibusque; maximis concinnatum auctum, perfectum: et ad vivum expressis iconibus supra quingentis illustratum.*" This author divides his work into two parts, the first containing twenty-nine chapters, the latter forty-two, under which he respectively describes the several tribes of insects, known among the early writers by the names of vespis, muscis, papilionibus, cicindela, blattis, cantharide, buprestis, meloe, &c. terms familiarized to the Linnæan scholar, but which are not always applied by Linnæus to the particular tribes of insects, designated by these names in the work of Moufet and his predecessors: a fault we trust to see one day amended.

Hollar gained considerable reputation by his iconical work, "*Mulcarum, Scarabeorum Vermiumque variæ figuræ et formæ omnes primo ad vivum coloribus depictæ et ex collectione Arundeliana,*" &c. published at Antwerp in the year 1646. The drawings were preserved in the Arundel cabinet; the plates are etchings in the usual style of its author.

About an hundred and fifty pages of the extensive work of J. Jonston, "*Historia Naturalis*" is devoted to the subject of insects, which tribes he distributes into four books, the first of which treats on terrestrial insects provided with legs and wings, the second of terrestrial insects which have feet and no wings, the third of the terrestrial apodal order, and the fourth of aquatic insects. These are illustrated by twenty-eight plates engraved on copper by the author, who was doctor in medicine.

Few authors are condemned with more critical severity than Jonston; his work is certainly a compilation, and as it has been stated, his materials are mostly taken from the works of Aldrovandus, Moufet, and others. Forskal denominates him a persevering compiler, and at the same time observes that he has not added a single remark to what was before discovered. These observations appear in the "*Amœnitates Academicæ,*" in which there is also another paper by Bladh, where we find the same sentiments repeated: The opinion thus expressed is known to have the sanction of Linnæus. This deficiency in the arts, to which he aspired, is warmly censured by Lyonet, who declares his butterflies to be of unsufferable deformity, and in form, or outline, to be constantly alike in all the figures. As an artist, nevertheless, he had his admirers: if we can place any reliance on the truth of his biographers, he was not destitute of ability. Moncoyons says, he saw in the hand of Mr. Plater of Basil a set of drawings executed by him with tolerable accuracy. And Lesser himself owns that many years ago he was shewn others very prettily painted by him on blue paper, in the possession of a nobleman belonging to the household of one of the kings of Poland.

The work of Jonston, which is in folio, and dated 1657, was published at Amsterdam. In the year following, we meet with an English translation of Moufet's work, printed by Topf, chaplain of St. Botolph's, in London. Nearly about the same time the work of Goedart, a Flemish painter, made its appearance in Holland in the language of that country. The last mentioned production deserves more explicit mention, for we think its merits have never been very candidly

estimated.

estimated. The engravings are described as of miserable execution, and the figures so indifferent in point of resemblance to the objects intended, that they could only in particular instances be understood; and again, on the contrary, the details are represented as so defective, that unless accompanied by his valuable plates, they would be useless. So much is advanced by his various annotators, and yet with all these imperfections, those individuals have condescended at different times to favour the world with translations of his work, originally written in Dutch, into the Latin, French, German, and English; and with various editions of the plates also. The truth is, that Goedart was a painter; the mere describers, from unworthy motives, were offended that he should presume to write, while they professed to be enraptured with his talents in the arts; and the artists denied him praise because they considered him as a naturalist, not a painter. Were this work of Goedart the production of our days, it would be undeserving of comment; but let us consider the period in which it was produced, and abating our expectation of excellence in those times either in the accuracy of observation, the history of insects, the style of language, or correctness of design; and we must acknowledge it in every respect as a valuable performance. The best of his annotators, even the ingenious Lister, to whom the original work was certainly under most obligation, has committed several errors in endeavouring to correct him.

For the space of about twenty years Goedart devoted great attention to the study of insects. He followed them through their progressive changes with great precision: this renders his book more extensively acceptable, and his figures, which have never been surpassed by his predecessors, are for the most part so far correct as to be understood. The Dutch edition of Goedart's work being soon sold off, the first volume of a Latin translation, by Dr. Mey, minister of Middleburgh, was brought forward under the title of "Metamorphoses et Historia Naturalis Insectorum," in the year 1662; and a second volume also, in the same language, translated by M. P. Veezaerdt, minister in Zealand, who added thereto some remarks of his own. Another translation of this latter part was afterwards published by Dr. Mey, with a farther addition of notes. Lister allows those annotators no credit for their labours; Goedart, he observes, left his writings in Dutch; "His Latin interpreters," says he, "have added comments indeed, but were men wholly ignorant in natural history, and their comments are mere rhapsodies, and altogether impertinent to the explication of any one history of Goedartius." Dr. Lister re-arranged and corrected this work, and added at the same time many curious observations.

A history of animals and minerals, in the course of which the subject of insects is noticed at some length, appeared in London in 1661, under the title of "Πανζωοριχτολογία."

The invention of the microscope opened to the curious a new opportunity of penetrating into the mysteries of nature, and discriminating with accuracy the most delicate organs of the minor tribes of animals, which from their minuteness had evaded observation before, and among these the insect race alone constituted such a vast proportion, that we may attribute to this cause that spirit and perseverance with which the study of these minute bodies was pursued about this particular period, and for the space of some years after. The era of this invention is ascribed to the year 1680, and although this does not appear to be strictly accurate, since an apparatus corresponding with it was in use at the earlier date of 1618, and that glasses possessing the power of enlarging the appearance of objects very considerably were

known among the ancients; yet, upon the whole, it may be concluded, that what is now understood by the microscopical instrument, received so much improvement about the time first mentioned, that, in qualified terms, we must date its invention from that period. The discoveries made by the assistance of the microscope within a few years after this time renders it a memorable epoch in the science of natural history, and so far as relates to insects, it is probably owing to the introduction of this valuable instrument into general use, that the names of Hooke, Power, Pierre Borel, Bonomo, Antoine Van Leuwenhöek, Joblot, and Hartsoecker (the latter of whom detected the circulation of the fluids in insects); and many other inquisitive individuals appear in the list of entomological physiologists, or anatomists.

The work of Power is in quarto, and was printed in 1654; this relates slightly to insects as objects of microscopical investigation. Hooke's "Micrographia" appeared the year after, and treats of insects in the same view. In the memoirs of the French Academy of Sciences in Paris, for 1666, there are some entomological observations by Mignot de la Voye; and in the fifth volume of the Philosophical Transactions a paper relating to "insects lodging themselves in willows," by King and Willughby. But the letters of Lister, which also appeared about the same time, or within the course of five or six years after, are still more valuable; among these are "letters concerning a fly that is viviparous, and concerning an insect feeding on henbain." "A considerable account touching vegetable excrescencies;" "Letters about musk-scented insects, vegetable excrescencies, and ichneumon-worms;" "A Letter containing the projection of the threads of Spiders, and Bees breeding in cases made of leaves, a viviparous fly, &c."

A small number of the insects indigenous to Britain is described by Christopher Merret, in his "Pinax rerum naturalium Britannicarum," &c. published at London in the year 1667.

An account of the tarantula engaged the pen of Wolfertus Sanguerdus (a medical professor) about the middle of this century; his work, entitled "Tractatus physicus de Tarantula," appeared in the year 1668; it is a small duodecimo of seventy pages, and was printed at Lyons. The general work of an English entomologist, Charleton, was the same year published in London, under the title of "Onomasticon Zoicon, pluriorumque animalium differentias et nomina propria pluribus linguis exponens," in which we have a systematic arrangement of insects after the manner of Aldrovandus. There is a mantissa of this work printed in folio in Oxford, in 1677.

Another work on entomology, a treatise professedly elementary, was published at Leipsic, the year after the first part of Charleton's work appeared. It is in quarto, and is entitled "Dissertatio de Insectis in Genere," &c. Jacob Wolff, professor of medicine at Jena, was the author.

Redi's "Experimenta circa Generationem Insectorum," for the time in which it appears (1671), is an intersting little book. Its author combats the doctrine of equivocal generation, maintained among the ancient philosophers; and deduces its fallacy from a variety of experiments and observations of great critical accuracy; in the course of which he demonstrates that every living creature is produced from an egg. The same work contains about thirty figures of the lice peculiar to particular birds, such as the pigeon, swan, pie, heron, &c. The same writer also published his work on the generation of insects in his native language, "Esperienze in torno alla Generazione degl' Insetti," 1688. There are several useful tracts by Redi on natural history;

history; but the above-mentioned is that which principally relates to entomology.

Another curious work, " *Experienze intorno alla Generazione dellè Zanzare,*" a small tract of about twenty pages, and embellished with one plate, was published in 1679. It is entirely confined, as the title implies, to the common gnat (*Culex pipiens*), and is written by F. P. Sangallo.

A writer, whose celebrity for his anatomical knowledge of insects can never be erased, while the science itself continues to be respected, is the next in order for our consideration: this is the indefatigable Swammerdam. One of the most important works of this acute observer of nature, his general history of insects, bears date 1669. We allude to the first edition printed at Utrecht, in the Dutch language, under a Latin title, "*Historia Insectorum Generalis; ofte algemeenvver handeling van de bloedeloose Dierkens.*" Of this work it has been well observed by a German critic, that it has no other fault than that of being written in a language not generally known. The work, in this original state, is in the quarto form, comprising rather more than two hundred pages, and is illustrated by figures contained in thirteen copper-plate engravings.

Some years passed away before the excellence of this work, the admiration of the learned in later times, was in any manner acknowledged; and the fate of Swammerdam, a man who, in the generosity of his mind, had exhausted the greater portion of his life in the completion of a work, so wisely calculated to enlarge the boundaries of human knowledge, affords another and very striking instance of genuine worth neglected:—another example of that culpable spirit of ingratitude which living merit so rarely fails to experience, in reward for the most splendid services their talents confer upon an illiberal world!—Chilling thought! that gloomy reflection which oftentimes suppresses the bright, the enviable, but too fatal exertions of genius, and shrouds the mind in apathy and indifference! No sooner was the death of Swammerdam announced, than his merits were discovered; and an anonymous translator rendered his book into French. Almost immediately after, another appeared in Latin; and after some time, another in English: all which contributed, but too late, to the author's fame. He died in 1680. The first French translation is dated 1682, and, like the original, is in quarto, and embellished with plates. The Latin translation corresponds with the two preceding, except that Hennius, in a second edition of the Latin copies, enlarged one chapter which treats on the analogy between insects and other animals and plants. The first Latin edition, "*Historia Generalis Insectorum, Latinam fecit H. C. Henninus,*" was printed at Lyons in 1685; the augmented copy in 1693, at Utrecht. The English translation is by Thomas Flloyd, and is printed with the edition of the "*Biblia Naturæ,*" in our own language, published in London, in 1758.

The latter work of Swammerdam was introduced to the public under very extraordinary circumstances. Such was the ill success of his former writings, that the "*Biblia Naturæ,*" after being prepared in manuscript for press, was left unpublished. No bookseller would venture to print it at his own risk; and the means of Swammerdam were inadequate to its production. At the death of the writer, M. Thevenot, his friend, became possessed of his papers, and with the copy of this among the rest. With him they remained some time, and then passed into the hands of Du Verney, an able anatomist, who enriched his own cabinet with the manuscript of this work. With him it lay buried, till the zealous and illustrious Boerhaave purchased them; and he was no sooner possessed of it than he hastened to

communicate this treasure to the world, and it was accordingly put to press in 1736. He included in this publication the former works of the author, and published the whole under the title of "*Biblia Naturæ, sive Historia Insectorum Belgicæ, cum Versione Latina H. D. Gaubii, et Vita Auctoris per H. Boerhaave.*" This work is in folio: the first volume, consisting of five hundred and fifty pages, appeared in 1737; and the second volume, of much greater bulk, and with many plates, in the year following.

The system proposed by the author of this work, for the arrangement of insects, differs so materially from that given by any preceding author, that we cannot avoid considering it immediately relevant to our present subject. The general or principal classes into which insects are divided in his system amount to four; and the characters of these relate to the metamorphoses the insects undergo, rather than to their appearance in the perfect state, the first class excepted.

The first of these four classes comprehends those subject to no change of form, but which quit the egg in the same state and appearance they are to retain during life. This class includes spiders, onisci, &c.; and must be therefore understood as admitting of an increase in bulk, though not undergoing any change in form.

The second class includes those which, after leaving the egg, appear under the form of an insect without wings, the other members formed; in which state it eats and grows, till, having passed into the second or nymph state, it issues from thence with wings, and is in a condition capable of propagating its kind. The locusts and dragon-flies are included by its author in this class.

In the third class, the animal, after having issued from the egg, where it remained in a disguised state, and without food, appears under that of an insect which eats and grows, while the members of the animal into which it is to be converted are formed under the skin, and which it at last quits, and becomes a nymph or chrysalis (of the dormant kind). This class includes moths and butterflies, &c.

The fourth class consists of those which, having arrived at the nymph state, like those before mentioned, do not divest themselves of the skin, in order to enter into that state, but assume the form of the nymph under its skin, where it continues shut up, till, quitting two skins at once, it comes forth in the perfect state. The insects of this class, according to its writer, are exemplified in the ichneumon.

There are some few small tracts published by this author during his life, neither of which is of material consequence, except that on the natural history and anatomy of the ephemera horaria, "*Ephemeræ Vita, of afbeeldingh van 's menschen leven, vertoont in de Historie van het uligent ende een-daghevent Haft of Oever-aas,*" a work in octavo, printed at Amsterdam in 1675. Immediately after the author's decease, namely in 1681, there were no less than two translations of this work; one in quarto, in English, and printed at London; the other by M. Thevenot, at Paris.

No work materially important on the subject of entomology appeared after the first edition of the work of Swammerdam, till the years 1678 and 1679, in which Lister published his valuable history of English spiders, and Madame Meriau her extensive work on the metamorphoses of lepidopterous insects. In the interval between there were several publications, which, though not of the most valuable kind, are sufficiently interesting to claim remark. Claude Perrault, one of the ablest writers on exotic insects of his age, and author of several papers in the *Memoirs of the French Academy*, produced a work in folio at Paris, in 1671, which

## ENTOMOLOGY.

treats on insects, under the title of "Memoirs pour servir à l'Histoire naturelle des Animaux;" and to this some additions were made in 1676. The work of Ferraud of Naples also relates to insects, among other animals; and this appeared in 1672. The year after Frenzelio submitted his "Insecta novifolia cum nive delapsa;" and at Franckfort on the Main, D. W. Mollerus brought forward his "Meditatio de Insectis quibusdam Hungaricis prodigiosis anno proxime præterito, ex aère una cum nive in agros delapsis," an useful treatise of 120 pages, with two wood cuts. In 1675, George Berelio printed at Upsal his elementary tract, *περί τῶν ἰνσέκτων*. The same year also, Samuel Bochart published his "Hierozoicon, sive bipartitum Opus de Animalibus sanctæ Scripturæ." Müller, in 1676, gave an orationary paper on the tarantula spider, "Dissertatio de Tarantula;" and Hermannus Grube, a curious little octavo volume on the same subject, "De Tarantula, et vi Mulices in ejus curatione, conjecturæ physico-medicæ."

Dr. Lister distinguished himself in the annals of entomology about this period. Previous to the publication of his "Historia Animalium Angliæ Tractatus de Araneis," several papers by this author appeared in the Philosophical Transactions, the principal of which relate to this tribe of creatures; such as his observations on the darting of spiders, in the fourth and fifth volume; his paper entitled, "Some Inquiries concerning Spiders;" and his "Tabulæ compendiariz Araneorum Angliæ," in the sixth volume. Lister's work on spiders, before mentioned, relates chiefly to those indigenous in England, and are arranged and designated by concise specific characters with much science, corresponding with that adopted afterwards by Linnæus. This is in quarto, and was printed at London in 1678; the appendix, "De Araneis addenda et emendanda," &c. in 1681. There is a translation of this work in the German language, by F. W. H. Martini, printed in 1778.

We are in possession of the first translation of the works of Goedart by Lister, a book printed at York in 1682, under the following title, "Johannes Goedartius of insects, done into English and methodized, with the addition of notes; the figures etched upon copper by Mr. F. Pl." The name of Lister does not appear; but the initials at the close of the address to the reader are M. L.; and in our copy, the letter L is rendered Lister, in the hand-writing of an entomological collector well known in the earlier part of the last century. The latter circumstance, though not apparently of much moment, is related because the fact might admit of doubt, the work being anonymous, and perhaps forgotten. The impression consisted, as the preface acquaints us, but of 150 copies, which were intended only for the curious; and in the course of nearly 130 years, it may be naturally concluded many of these must have been lost. The notes in this book are very copious. In 1685, an edition of Goedart by Lister appeared in Latin. The translator in this, as in the former work, distributes the materials of Goedart's performances into a new form of arrangement, the merits of which are too obvious not to be considered as an improvement on the original production. He divides them altogether into ten sections; for they are not strictly, in every instance, what we might denominate orders; in some they certainly are. The first, second, and third sections are of the lepidoptera kind, and very clearly discriminate the papiliones from the moth tribe.

The 1st includes those with erect wings; these are the butterflies which fly by day, and the chrysalids of which are angular.

2d. Moths with the wings placed horizontally, and which proceed from the caterpillars called geometræ by

Goedart, because of their gait, which is like that of a measurer of land.

3d. Moths with dejected wings, or those with hanging wings fitting closer to the body than in either of the two preceding.

4th. Libellulæ, or dragon flies.

5th. Bees.

6th. Beetles.

7th. Grafshoppers.

8th. Dipterous flies.

9th. Millepedes.

10th. Spiders.

Goedart spent forty years of his life, as he expresses it, "daily conversing with insects;" and from the course of his observations, it is manifest he was well acquainted with his subject. Lister is nevertheless unwilling to concede this point: he neither allows him credit as a naturalist or a writer, at the same time that he extols his excellent skill in limning. These opinions are delivered in a style of affected superiority over his author, neither becoming, nor strictly true; and seem to be dictated so nearly in the spirit of some more modern critics, that one cannot avoid smiling at the comparison. "Goedart," says he, "after forty years attention, seems to have made little advancement in his skill in the nature of insects: he seems rather to have diverted himself with them, than to have given himself any trouble to understand them; and yet after all, you will find him every where very just, and true in his observations, but in many places very short, and hardly intelligible." Our English annotator gained no reputation on the continent for these general remarks, although the merit of his notes relating to the metamorphoses of insects was acknowledged; the works of Goedart still maintained their credit.

Maria Sybilla Merian, vel Gräffinn, the wife of John Andrew Gräffinn, was a native of Franckfort on the Main, and early in life imbibed a taste for the study of insects, from being occupied at times in painting these pleasing objects as embellishments to her flower-pieces. The task of painting insects was performed by this fair artist with no very falliduous share of accuracy. In point of drawing she rarely excels; and her productions, though splendid memorials of her talents, and the great encouragement she obtained, are marked by a peculiar exuberance of style incompatible with any faithful resemblance of nature. Her first work was published in 1679, and relates to European insects, chiefly those of the lepidopterous order, with their changes, and is entitled "Der Raupen wunderbare verwandelung, und sonderbare blumen-nahrung;" another part appeared in 1683. These were published at Nuremberg. In 1718, another work by the same authoress was published at Amsterdam, called "Erucarum ortus, Alimentum et Paradoxa Metamorphosis." After this we have an history of the European insects, rendered from the Dutch text of Madame Merian into French, with an augmentation of the description of the plants by J. Marvet, a work printed in folio at Amsterdam, in 1730. But the best of all her publications came out at the Hague in 1726, in a folio of superior size, with the title "De Generatione et Metamorphosis Insectorum Surinamensium," &c.; the materials for which were collected by herself, or under her own inspection in Surinam. This lady had made a voyage from Holland to South America in 1699, for the avowed purpose of forming a collection of natural curiosities for this work, and was occupied at Surinam during the space of two years in taking drawings and descriptions of various objects for this purpose. This work is not entirely devoted to entomology, as, besides insects, it contains a miscellaneous

lineous assemblage of toads, lizards, serpents, and other reptiles, and likewise a pretty extensive number of plants.

In the Philosophical Transactions are to be found some observations concerning insects, made in Virginia in 1680, with remarks by J. Petiver. Hoppio, in 1682, published at Jena a dissertation on the gryllus migratorius. Two years after, another small tract appeared also at Jena, a paper on ants, "Respublica Formicarum," by A. Schmidt.

The fifteenth volume of the Philosophical Transactions affords an account of the "Connough-worm," by Wm. Molyneux, a paper afterwards translated into Latin, and inserted in one of the continental journals under the title of "Observatio de Insecto Hibernico vocato Connough-worm." Some few entomological observations of a miscellaneous nature, extracted from the manuscript history of Pembroke-shire by George Owen of Henllys, lord of Kemmes, occurs in the eighteenth volume of the same Transactions. The original MS. of this history we have seen in the British Museum. Besides the above, the Transactions about the same time contain several interesting papers relative to insects; as Allen's account of the gall-bee, and the death-watch, in vol. 20. "A Letter concerning an Insect commonly called the Death-watch," vol. 22. which respects both ptinus pulsator, and hemerobius pulsatorius, written by William Durham; and also a supplement to an account of pediculus pulsatorius or death-watch, in vol. 24.

But, in point of priority, we ought previously to have mentioned the earlier works of Leeuwenhoek; a writer whose astonishing assiduity, aided by means of powerful microscopes, has contributed more than any other man, except Swammerdam, to disclose to our view the wonders of the invisible creation, in the sphere of which the minima of the insect race become of the first consideration. One of the first papers of this intelligent observer appears in the eighth volume of the Philosophical Transactions, and is entitled "A Specimen of some Observations made by a Microscope contrived by M. Leeuwenhoek." His communications to the world after this became numerous; and, as the object of his pursuit was of a nature to stimulate a spirit of investigation, it could scarcely at the same time fail to excite controversy. It led, therefore, to the production of many papers by different writers, all which tended, in some degree, to the further elucidation of the subject. As these, however, are only in part connected with entomology, it would be fruitless for us to follow, through the varied branches of discussion, and to select those particular passages which relate to our present inquiry; for these we refer the curious reader to Transactions of the Royal Society, from the eighth to the thirty-second volume; and to various publications printed at Leyden and Delft in 1686, 1693, 1697, 1704, &c. Among the principal works of Leeuwenhoek, are "Anatomia, seu interiora rerum, cum animatarum tum inanimatarum (sic) ope et beneficio exquisitissimorum microscopiorum detecta," 1687; "Arcana naturæ detecta," 1695; and "Opera omnia," 1722; an English edition of the select works of this author was undertaken in London in 1798.

Geyerus, in 1687, was author of a medical tract in quarto printed at Leipzig and Frankfort, called "Tractatus physico-medicus de cantharidibus," and which, as the title implies, relates to the medicinal properties of those well known insects, the cantharides. Bononius, in the same year, published a letter at Florence, in which he enters on an extensive detail of his observations on many insects, with the microscope, and lays claim to several discoveries. And J. F. Griendel, Von Aeh, canon of the order of the Holy Ghost, produced his "Micrographia nova" at Nuremberg

also at this time; a quarto volume of sixty-four pages, some of which are dedicated to his microscopical observations on insects.

The work of Stephen Blankaart of Amsterdam made its appearance in 1688. Its author, a Dutch physician, was an assiduous collector, and in this instance produced a work, the plates of which have been as much admired for the beauty of their execution as the work in other respects has been condemned. Frisch, and after him Lyonet, consider it as an indifferent production. It relates chiefly to the larva of different insects, as the caterpillars of seventeen lepidopterous insects, twelve maggots of flies, and a few other insects, amounting altogether to forty-seven subjects. The title is, "Schou Berg der Rupsen, Wormer, Maden en vliegende Dierkens daar uit voort-kommende." The paper of John de Muralto, and also that of C. Mentzelius, relating to different insects, appeared about this period; and the work of John Cyprien, "Historiæ Animalium," was also printed in 1688; it was published at Frankfort, and relates to insects among other animals. A small tract, an oratory paper of eight pages, with a single plate, entitled "Chymica Formicarum," is from the pen of professor Sperling in 1689. Koenig's "Regnum Animale," &c. printed in 1690; Bilberg's "Locustæ," a dissertation, printed at Upsal in 1690; and "Historia Vermium" by Jungius, printed at Hamburg in 1691, are all interesting, and a paper by Sedileau, published in 1692 in the Memoirs of the French Academy, is rather curious; this latter is denominated "Observations sur l'origine d'un espece de Papillon," and the insect treated upon is bombyx pavonia γ major. The prodigious ravages occasioned by the swarms of locusts which, in the month of August 1693, over-ran Germany, and extended their scattered legions throughout the rest of Europe, even to the borders of the most northern countries, were an event of such an afflicting nature, that it could not fail to engage the observations of many writers, in the number of which we meet with the names of some naturalists of ability, whose dissertations on this occasion are acceptable. Treunero, Hebenstreit, Woollenhaupt, Crellius, Kirkmajor, and Ludolfus, wrote at this time on the subject, relating the particulars of their appearance, the devastations committed, and the most effectual means of destroying them. The species was the common migratory kind, gryllus migratorius. These tracts were generally trifling in point of size, that of Hebenstreit, however, "De Locustis immenso agmine aërum nostrum impletibus, et quid portendere pütentur," consists of 65 pages and one plate, and that of Ludolphus, entitled "Dissertatio de Locustis, anno præterito immensa copia in Germania visis, cum diatriba, qua sententia autoris de  defenditur," is a folio of eighty-eight pages, and embellished with figures.

Albino published a small tract on the cantharides in 1694, and the following year "Jacobi Petiveri Musæum," a small octavo, was published in London. These, with the elementary work of Jacobæus, "Dissertatio de vermibus et insectis," and that of Baglivus, printed at Rome in 1696, on the effects of the bite of the tarantula, and a paper of Homberg on the libellula virgo in the Memoirs of the French Academy for 1699, appear to be the only publications deserving of mention till the commencement of the eighteenth century.

The earlier part of the eighteenth century forms an era in which the science of entomology was cultivated with the happiest success. It is with some pride also, we observe, that even in the comparatively improved state to which the science had then attained, it derived no incon-

siderable advancement through the labours of our own countrymen. The works of Ray and Lister, with those of Petiver in England, and those of the indefatigable Reaumur in France, contributed essentially to this purpose, and to the present day serve in some measure to maintain the reputation of science. The works of those authors were succeeded within the first fifty or sixty years by other works of high consideration, as will be found hereafter. In the interval of time that elapsed between the publications of those more extensive and valuable works, others of less importance, but which yet deserve mention, made their appearance; as, for instance, in 1701 the small, but curious dissertation of Heucherus, called "*Araneum homini perniciosum et salutarem*;" the little treatise by Vallerio of Upsal on the tarantula, published the year after; the entomological part of the work of G. B. Rumphius, in 1705, and that of Ruifsch, "*Theatrum universale omnium animalium*," published in 1710—1718. Henninger produced a small medical tract relating to millepedes, in 1711. Wedelio on an old subject, the utility of the cantharides, in the *Materia Medica*, at Jena, in 1717; and Whitaker, the year following, on the same insect: the remarks of J. Pontedera, "*De Cicada*," &c. annexed to his botanical work; and two tracts by Laurentius Roberg, medical professor at Upsal, "*Formicarum Natura*," and "*Libella infesta*."

It was in the year 1702 that Petiver produced the first decade of his "*Gazophylacium naturæ et artis*," the publication of which was carried on progressively till for about ten years after, during which period the work was extended to ten decades, each containing plates exclusive of the "classical and topical catalogues." This work relates to insects among other animals, plants, and fossils. About twelve months before the author's death, which happened in 1718, there was, however, another work printed by him under the title of "*Papilionum Britannicæ Icones*," &c. and which, as the title expresses, relates to the English butterflies, and is entirely confined to entomology.

A work by Ray, appropriated to this branch of science, was published in 1705, under the title of "*Methodus Insectorum, seu in methodum aliqualem digesta*," and which can be considered only as the introduction or prelude to the great work, "*Historia Insectorum*," which the world received in 1710, through the care of Dr. Derham; for Ray did not live to see it published.

This celebrated naturalist divides all insects into two principal classes, those which undergo transformation in their form, and such as do not pass through any transformation after being produced in the first instance. Each of the two principal classes are sub-divided into several orders, which are variously characterized, as by the number of the feet, or by being destitute of those limbs. Some are determined by the habitation of the insects; by the size, or conformation of various parts of the body; by the odour they emit; the form of the caterpillars, and various other peculiarities. This arrangement is in part conformable with the writer preceding; the *intransmutabilia*, or order of those which do not pass through any metamorphoses, is due to Willughby; and the three orders of changeable insects correspond with the 12th, 13th, and 14th orders of Swammerdam's classification. His class of changeable insects is divided into several families, as *vaginipennes*, from having the wings covered with a sheath, *papiliones*, *quadripennes*, *bipennes*, &c. There is an appendix to this work by Lister, "*Appendix de Scarabæis Britannicis*," &c. Ray, like many other writers, includes certain tribes of the *vermes* with insects, from which they are separated by Linnæus; it is possible that Ray might conceive what has been since proved by in-

dubitable authority, that some few, at least, of the supposed *vermes* are no other than the larvæ of insects.

The work of Albin, for the time in which it was executed, was considered as an elegant publication; it is in one volume quarto, containing one hundred copper plates, with a brief description of the objects represented in each, and was originally sold at four guineas a copy, a great price in those times, being published in the year 1720. If we mistake not, another edition is dated a few years later; there is certainly one printed with notes and observations by Dr. Derham, in 1749. Albin was author of a work on English spiders, in which the lice of several animals and birds are represented from the plates of Redi.

At the same time that Albin was engaged in the preparation of the above-mentioned work in England, J. L. Frisch, rector of the Royal Academy at Berlin, was occupied on his history of the insects of Germany, "*Beschreibung von Insecten in Deuschland*," the first part of which appeared in 1720; the whole work consists of thirteen parts, and each part is embellished with three plates. Copies of this work have been printed since that time; the latest we have seen bears date 1766.

Valisnieri, in his work, entitled "*Esperienze et Osservazioni intorno agli insetti*," published in 1730, distributes all insects into four classes, according to the different places in which they are found. The first comprehends those insects which live on plants; the second, such as live in water and other fluids; the third, those that live in the earth, or among stony substances; and the fourth, those which subsist on the other animals, or in their bodies.

Reaumur produced the first volume of his "*Memoirs pour servir à l'Histoire des Insectes*," at Paris, in the year 1734. The five succeeding volumes appeared between that time and 1742. This voluminous work contains some thousand pages, and nearly two hundred plates; and is one of the best productions on the subject that has been submitted to the world. There are two editions of this work, one published in Paris by its author, in quarto size; the other is in octavo, a pirated concern by the Dutch booksellers.

After the works of Ray, Lister, and Petiver, the intelligent entomologists of our own country, in the commencement of this century, the name of Bradley ought perhaps to have been introduced. His publication, "*A Philosophical Account of the Works of Nature*," which was printed in London so early as the year 1721, contains a brief account of insects. This author, though a professor of botany in one of the universities, seems not to have been possessed of any very extensive or accurate information on this subject of entomology; his work at least abounds in the marvellous, but was, perhaps, for this very reason, more likely in his time to have been perused with pleasure by the common reader. As a popular work, it was not in other respects without its advantages. The works of Reaumur in France contributed materially to facilitate the study of entomology on the continent. And about the same time that he was engaged in this field of enquiry, several tracts and papers made their appearance from other individuals. In the memoirs of the French Academy for 1731, there is one entitled "*Expériences sur les Scorpions*," by Maupertuis; and in 1734, some others by Trew, as "*Insectorum quodam genere*," "*De duabus Ericis*," and "*Peculiare quoddam Quercus exerescentiarum generis*," all which are inserted in the "*Commerc. Literar.*" of Nuremberg. These papers immediately preceded the publication of the first entomological work which the celebrated Linnæus produced to the world.

The principal writings of Linnæus on this branch of natural

tural science are to be found in his deservedly esteemed production the "Systema Naturæ, five regna tria naturæ systematice disposita per classes, ordines, genera, et species;" the first edition of which is in folio, and was published in 1735. Linnæus in this work distributes insects into four orders, according to the number and form or nature of their wings, under the several names of coleoptera, angioptera, hemiptera, and aptera. The first order contains those insects which have covered wings; the second those with naked wings, as butter-flies, dragon-flies, ephemera, &c. In the third, he enumerates crickets, locusts, bugs, &c.; and in the fourth, those which have limbs, but no wings, as the spider, lobster, &c. Besides these four orders, this primary arrangement of insects comprehends three other orders of animals, referred since to the vermes class, but which, at the period of the first publication of the "Systema," Linnæus considered to be genuine insects. The first of these includes all creeping "insects" whose body is naked and destitute of limbs, as the earth-worm and the leech: the second, both land and sea-shell animals; and the third, those furnished with limbs, as the echinus, asterias, &c.

Linnæus by no means deviated from the received opinion of his time, in placing the first and third of these last mentioned tribes of animals with insects. These bodies were considered as appertaining to the insect race by most of his immediate predecessors, and by some naturalists in earlier times. In a subsequent edition of the Linnæan work, these orders are separated, and the latter constituted into a distinct class after the manner of Aristotle, who points out the natural obvious difference which prevails between these two orders of animals with so much clearness, that we are not without some surprize his example was overlooked by Linnæus in the first instance. Linnæus, according to this plan, in his later works, separates the echini, &c. under the denomination of vermes. The insects alone were then extended by him from four to seven orders. This is the arrangement which his class "Insecta" finally assumed in the edition of 1767, and which is still adopted by the admirers of Linnæus. The following are the definitions of the several orders established by this eminent naturalist.

*Coleoptera*, such as have crustaceous elytra, or shells, which shut together, and form a longitudinal suture down the back of the insect, as in the chafer-beetle. In most insects of this class, the elytra cover the abdomen entirely, in others but partially, as in the ear-wig, &c. The word is derived from *κολοῦς*, a sheath, and *πτερόν*, a wing.

*Hemiptera*, which have their upper wings most commonly half crustaceous, and half membranaceous, not divided by a longitudinal suture, but incumbent on each other; as in the water scorpion and grasshopper. From *ἡμισυ*, half, and *πτερόν*, a wing.

*Lepidoptera*, having four wings covered with fine scales in the form of powder or meal; as in the butterfly and moth, from *λεπίς*, a scale, and *πτερόν*, a wing.

*Neuroptera*. In this order the wings are membranaceous, transparent, and naked, and are generally reticulated with veins or nerves; the tail is without a sting, as in the libellula or dragon-fly. The term is derived from *νεῦρον*, a nerve, and *πτερόν*, a wing.

*Hymenoptera*, have four membranaceous wings, and the tail furnished with a sting for various purposes, as in the wasp, ichneumon, &c. From *μῆνι*, a membrane, or pellicle, and *πτερόν*, a wing.

*Diptera*, with two wings only, and poisers as in the house-fly; from *δύο*, two, and *πτερόν*, a wing.

*Aptera*, have no wings; as the spider, &c. from *ἀ*, without, and *πτερόν*, a wing.

The great perspicuity of the Linnæan system of entomology arose from its author having made choice of the most obvious characters which insects afford for the leading distinctions of his orders, such for instance as the number, texture, and position or folds of the wings, or the absence of these parts; and in the construction of the genera, the like attention being devoted to the form of the head, thorax, and wings; and in particular to the structure of the antennæ: these latter being conspicuous in most insects, and so infinitely varied in their appearance as to constitute in general a permanent definition. That there are other characters which, in the opinion of later entomologists, are better adapted to the purpose of classification the reader must be aware, but these, although really preferable in some respects, are perhaps too minute to become always useful. The structure of the various parts of the mouth, the character on which the Fabrician system is founded, however definitive, and therefore excellent, requires that degree of attentive scrutiny in their examination, which is rarely bestowed by the ordinary observer of nature; and which cannot for this reason be so well calculated for the general purpose of discriminating the families of insects, as those which are at once too obvious to be mistaken.

The simplicity of the arrangement adopted by Linnæus, the celebrity of his name, and the princely patronage under which he wrote, conspired with other favourable circumstances to render this science more universally cultivated, admired, and respected about his time, than it had probably been at any former period. The credit due to this naturalist for his labours in entomology is great. This we allow, but, let us also remember, that he is not alone entitled to our commendation for the arrangement proposed in his work. We must in candour acknowledge the merits of many among his predecessors, who wrote under circumstances of less encouragement, and have nevertheless excelled in this science: men to whom the writings of Linnæus stand in a very high degree indebted, and without the aid of which it is impossible to imagine the system, which now commands our admiration, could have been produced, at least in its present state of purity.

From the various entomological works extant before the time of Linnæus, it may be collected that the history of these creatures was deeply investigated prior to the appearance of his writings; and even that system itself, the prominent feature of his labours, from progressive advancement, had gradually attained to a state of considerable perfection. In the works of Aristotle and Pliny, in those of Agricola, Aldrovandus, Frenzius, Mouset, Swammerdam, Ray, Willughby, Lister, Vallisneri, and various others whose names have been already repeated, we distinctly perceive, with some occasional variation, the outline of the superstructure raised in the "Systema Naturæ."

These valuable sources of information furnished him with abundant materials, from which he selected with profound judgment, and interwove with ability, industry, and success. Linnæus was in this respect commendable; he did not suffer his mind to be swerved on this occasion from any ambitious or innovating motives; and so far as he deemed it consistent with his plan, he appears to have adhered to the examples of his predecessors. The characters of his ordines are to be found in several earlier publications than his own, and so likewise are most of his genera, and the far greater number of his species. But these he remoulded throughout with so much skill, that this "Systema" constitutes the central point in which the scattered rays of natural science are concentrated with more precision than they really appear in the original authors, to whose industry he stands indebted. It

was in the concise and very expressive style which Linnæus adopts in all his works, and which was almost peculiar to himself, that he excelled.

Our limits are inadequate to the fair discussion of this important subject; and of this we feel so deeply sensible, that for the present we shall waive all further comment, reserving to ourselves a future opportunity for entering upon a more extensive view of the merits of the Linnæan system, as contrasted with those of other authors who have appeared since his time, and which have obtained the sanction of public approval.

After the first edition of the "Systema Naturæ," Linnæus wrote several papers on the subject of entomology; some of which are printed in the Transactions of the Royal Society of Upsal. One of the earliest of these appeared in 1739, under the title of "Om Renarus Brömskolor i Lapland;" and another dated Stockholm, in the same year, "Tal om Märkwadighter uti Insecterne." In 1746, we find a paper, jointly the production of Linnæus and Degeer, relative to the lantern-fly of China (*fulgora candelaria*); and about the same time, his "Fauna Suecica," an enlarged and improved edition of which was published in 1761. That elegant insect, *panorpa coa*, a scarce species at that period, forms the subject of a small Linnæan paper in 1747. His dissertations "Miracula Insectorum," and "Noxa Insectorum," bear the same date, 1752: they were both printed at Upsal, and possess merit: the latter is in particular valuable, from the object in the contemplation of the writer. Six years after this he produced a dissertation, called "Pandora Insectorum;" the year after, a paper on the coccus; and in 1761, his "Fundamenta Entomologiæ," a book in those days of considerable value as an elementary work, or introduction to this study. There is a translation of the tract by W. Curtis, printed at London in 1772. His last entomological paper is upon the genus *pausus*, a curious coleopterous tribe, distinguished by the comparatively enormous magnitude of the antennæ.

The work of L'Admiral, entitled "Naawkeurige Waarneemingen van Gestaltverwiffelende gekorwene Diertjes," appeared in 1740 at Amsterdam. It is in folio, and contains a series of elaborately finished etchings, which, though engraven in a dissimilar style, have somewhat the air of Merian's work on the insects of Surinam, or as is distinctly copied in the Aurelian of Moses Harris. The work of L'Admiral is confined to the European insects, of which it comprehends about fifty species of the larger kinds, and those principally of the lepidopterous tribe. These are represented in a heavy, though not unpleasing, and often very beautiful manner, in various attitudes, with large branches of the different kinds of plants on which they feed; and in most instances, the perfect insect is accompanied on the same plate with the larva and pupa. L'Admiral's work began in numbers, and was intended to contain, according to its author, one hundred plates and four hundred pages of letter-press. This design was never completed. There are few copies with more than twenty-five plates, and about five pages of letter-press. Our copy contains thirty-two plates and twenty pages, and is the most complete in this respect we have seen.

A small treatise relative to the larvæ of phalænæ, by Detharding, "Disquisition Physica Vermium in Norvegia, qui novi vili," was published in quarto in 1742. The same year, the tarantula spider engaged the attention of Francesco Serao of Naples, who on this subject only has given a quarto of two hundred and sixty pages, entitled, "Della Tarantola o vero Falargio di Puglia." The history of the tarantula about this time engaged the pen of several curious

persons; and, among others, N. Caputus had the year preceding published a book nearly the same size, "De Tarantula: Anatomie et Morfu."

The work of Lesser, "Insecto-theologia," &c. written in the German language, and better known from the French translation by Lyonet in 1742, entitled "Theologie des Insectes," is rather a curious than valuable publication. The success of this book in Germany renders it worthy of particular mention. The views of its author, (a clergyman at Nördhausen,) as he himself explains, was to "promote the glory of God." He does not aspire to the establishment of any new facts relative to entomology: his attention is directed solely to the selection of such anecdotes and particulars of the history of insects, gleaned from other works, as could be rendered a convenient medium for the theological remarks with which his pages abound. The piety of his mind we shall not distrust: to an entomologist his work is of no material worth; he was not very well acquainted with this subject, and his remarks are often erroneous. As a theological production, and in this view the author wished it to be considered, certain passages in the work of Lesser may have an useful tendency: it is calculated to expose some glaring errors in the writings of other theologians, who in a spirit of fanaticism had entered upon the same subject. One of his best chapters on this head is that relating to the "abuse of insects in theology;" in which he points out the gross outrage on reason committed by the pagans, in making certain insects the idols of their worship; and remarks how much more absurd it must appear, that the Jews and even Christians should have followed their example: a fact inferred by him from various authorities. The Jews are accused of stating many wonderful things relative to insects, which can only be considered as fables. Among others, after repeating the sacred text, 1 Kings, vi. 7. concerning the erection of the temple, which was "built of stone made ready before it was brought thither; so that neither hammer, nor ax, nor any tool of iron was heard in the house, while it was building," he states, that the Jews explain this passage in the following manner. The workmen, they affirm, employed a worm to shape the stones; which insect, named schamir, cut and broke them to pieces in places where applied. They add, that it was the figure of a grain of barley, and was kept in a leaden box, because, had it reached any rocks, it would have cleft and destroyed them. This fable, with some others invented by the rabbis, is particularly mentioned. Among the legends of Catholic superstition he selects other anecdotes equally remarkable. Baldus, he says, in order to prove the real presence in the eucharist, relates that a number of bees being found on holy ground, paid it homage, and carried a portion of it respectfully to their hive. Baptiste tells us, that a spider having accidentally fallen into the chalice, while St. Francis was saying mass, the holy man determined to swallow it; and adds, that the spider came afterwards out of the bone of his leg. But to conclude with one of these tales of fanaticism not unworthy of record with the rest: it is gravely stated that St. Francis, once walking in a garden, saw a grasshopper, which immediately quitted the plant it sat upon, and perched on his hand; he ordered it to sing to the praises of God, and with a pretty loud voice it immediately began a very fine psalm! If such holy impollures were actually listened to with any faith, the time of Lesser could not be misapplied, as a divine, in endeavouring to expose their absurdity.

Degeer published at Stockholm, in the year 1744, an interesting little octavo on the utility of the study of insects, called "Tal om nyttan, som Insecterne och deras Skärskådande,

dande, tilskynda öfs;" in which he points out the advantages likely to result from our acquaintance with this tribe of animals, and which appears to be the first tract expressly written under this view of entomology. About this same period, Röfel of Nuremberg, by profession a miniature painter, was engaged in the preparation of a valuable entomological work, the first part of which was shortly after produced to the world. This work bears the title "Der Monatlich-herausgegebenen Insecten-Belustigung," and consists of several volumes in quarto. The first part was produced in 1746, and two succeeding volumes in 1749 and 1755; to these a fourth volume was added by his relation Kleemann, 1761, two years after the death of Röfel; and since that period Kleemann has published three other parts in continuation.

Röfel does not adopt any scientific order of arrangement: his work was produced as a miscellany, and, according to the title, as an amusement in the study of insects. Many of the insects included are European; others are natives of Asia, America, &c. Besides insects, some few of the crustacea are contained; and a portion of the third volume is devoted to the vermes tribe. The text is in the German language, and exceedingly copious; the slightest peculiarity in every individual insect being descanted upon with as much minuteness as the more important details of its history. The plates are numerous and interesting. The supplemental fasciculi given by Kleemann, "Beyträge zur Natur-und Insecten-Geschichte," &c. relate to European insects, and a small number of the extra European kinds.

A tract, dedicated to the purpose of explaining the advantages arising from the study of insects, was printed in 1747, by C. F. Mennander, "Dissertatio de Usu Cognitionis Insectorum." Bazin, the same year, published his "Abregé de l'Histoire des Insectes, pour servir de suite à l'Histoire naturelle des Abeilles," in Paris; and in London, William Gould, "An Account of English Ants." T. C. Hoppe published, the year after, two small entomological tracts, as "Antwort-Schreiben auf Hrn Schreibers zweifel," at Gera; and "Eichen-Weiden-und Dornrosen," at Leipzig; and J. Dufield of London, six numbers of a natural history of English moths and butterflies, after which the work discontinued.

About this same period, or rather earlier, but certainly before the year 1749, a work was undertaken in London by Benjamin Wilks, under the title of "The English Moths and Butterflies, together with the Plants, Flowers, and Fruits whereon they feed, and are usually found." This publication, consisting originally of plates only, appeared in the first instance without a date. From collateral circumstances we are, however, enabled to state that it must have preceded the year last mentioned; because at that time the whole work, consisting of 120 plates, was nearly completed, as we learn from comments upon that work in the third volume of Röfel's *Insecten Belustigung*. The nature of this work is rather incorrectly stated in its title page; for the plants on which the groups of insects are respectively displayed are not those which constitute their natural food: they consist of gaudy flowers, auriculas, roses, monstrous varieties of cultured plants, fruits, &c. the introduction of which, in preference to their natural food, has incurred blame. But another charge, and one in our opinion of more importance, is brought against our author by Röfel; an imputation tending to depreciate the respectability of the English entomologists of that particular crisis, when the science ought, from the labours of former writers, to have stood in this country on very high ground, and the public judgment to have been so far matured as to

discover imposition. He plainly accuses our author of piracy; and when we reflect on the celebrity this work has heretofore enjoyed as an original production, it does attach some little reproach at least that facts stated with the utmost publicity on the continent should have remained unknown to us. The remarks are curious; and as in all probability they have not before met the eye of the English reader, we shall translate the passage in this place: "In dem nachtragoder 3," &c. "In the supplement, or third part of my Amusements of Insects, I have mentioned a certain work which Mr. Wilks in London publishes monthly, and promised that I would be more circumstantial at another time. Since then the plates amount to ninety, all which I have examined with great attention: they are as yet destitute of any description, which, however, is to appear at some future period. If the notice which accompanies these plates deserves credit, all those insects are drawn after life; but to those who know other works, and examine these plates with caution, it soon appears that the author has copied several from Albin's insects, from Merian's book, and a great many from my own. Whether he has been successful in his attempt, I leave to the judgment of others. An ape mimicks every thing, but does not always succeed. This may appear to many to be too severe; but let them consider that the author counterfeits the works of others, and gives them out as his own. I venture to assert that in the future description of his work, he will take care not to tell us from what books he has compiled his own; for he already strives to hide on his plates whatever he has copied from others, by reversing the figures, or by giving them a different position." Vol. iii. p. 192, A.D. 1749. This we must consider as in some measure the language of repentment for the liberties taken with his work: it is nevertheless in substance true; for the eye of the artist will perceive, on comparing the two publications, that Wilks has taken an unlimited range through the first volume of Röfel. The remarks are repeated at length, because we wish to impress on the public mind the value and importance of any genuine work, in preference to productions of this nature. Wilks was the publisher of "Twelve new Designs of Butterflies," in which the insects are disposed in stars, festoons, circles, or other whimsical groups, forming what are usually denominated "Butterfly pictures."

The first volume of the invaluable work of baron Charles de Geer, the "Memoirs pour servir à l'Histoire des Insectes," was printed at Stockholm in 1752, and was received with every demonstration of praise, to which its merits are entitled. From the testimony of the author's talents which this volume afforded, the continuation was expected with impatience; but nine years elapsed before the second volume appeared, and it was altogether twenty-six years from its commencement to its termination. It was completed in 1778, in which year the labours of its author closed with his life. De Geer was the author of many other publications, which are to be found dispersed through the Transactions of various learned societies; but that above noticed is the most considerable of his works.

Dr. Hill, in his history of animals, published in London in the year 1752, divides insects into three classes: the first of which, apteria, comprehends all insects without wings; the second, pteraria, is devoted to the winged kinds; and the third, called gymnarthridia, consists of those which have soft and naked bodies, and are furnished with limbs. The apteria is divided into two families; and pteraria, or the winged insects, into diptera and tetraptera, or those with two wings and four wings.

The "Entomologia Carniolica" of Scopoli appeared in

## ENTOMOLOGY.

1753. This author distributes all the insects of which he treats into orders, genera, species, and varieties, nearly after the manner of Linnæus; changing, nevertheless, the names they bear in the works of the latter for others he deemed more appropriate. Thus, for example, proboscidea is substituted for hemiptera, in reference to the beak by which these insects are distinguished; aculeata for hymenoptera, from the abdominal sting; halterata for diptera; and pedicellaria for aptera.

As a systematic work, this publication of Scopoli is of small importance; in other respects it is valuable. The arrangement of insects, better known on the continent as the system of Scopoli, appeared in a work, entitled "Introductio ad Historiam naturalem," printed so lately as the year 1777, and which, as the title expresses, does not relate exclusively to the science of entomology. He divides insects into five tribes, under the singular appellations of Swammerdamii-lucifuga, Geoffroy-gymnoptera, Roessli-lepidoptera, Reaumurii-proboscidea, and Frischii-coleoptera: by this means, identifying each particular tribe with the name of an author, who in his opinion had been most successful in the explanation of that to which his name is attached.

The order lucifuga includes two genera, crustacea and pedicularia; gymnoptera comprehends halterata, aculeata, and caudata; lepidoptera, the genera sphinx, phalæna, and papilio; proboscidea are divided into two parts, the terrestrial and aquatic; and the coleoptera, in the same manner, consist of two families, the inhabitants of the water and those of the land.

The ardour with which the science of entomology was cultivated about this period in various parts of Europe, is to be ascribed to the occasional labours of Linnæus and his immediate coadjutors, whose example excited the most laudable assiduity; and though no work of any material consequence appeared exactly at this time, we may safely conclude that this spirit of emulation laid the foundation of several which were submitted to the world a few years after. Among the entomological tracts and papers of this time, some only are worthy of notice. Kalm, a name familiar to the botanist, bestowed attention on this subject, as we perceive from a paper on a species of cicada, (septemdecim,) written in the Swedish language; and also from another by the same author on acarus americanus: these appeared in 1754. The year after G. W. Sigwart treats slightly on coleopterous insects; and Sauvages produced some papers of little moment in the Memoirs of the French Academy. And now we proceed gradually to the consideration of other works of greater consequence; the useful work of Clerk on the spiders of Sweden, printed in 4to. at Stockholm, in 1757, is one of the best works extant on this curious tribe. Another production by the same author is also valuable, his "Icones insectorum rariorum," a thin and small quarto, published two years after. Indeed, this last mentioned work may be considered as having the immediate sanction of Linnæus, from being produced under his own direction, and, we believe, inspection. The work contains a moderate number of coloured plates, some of which are appropriated to the display of select exotic insects of the moth and butterfly tribe, and others to the more choice and rare lepidopterous insects of Europe, all which are highly finished in colours. There were only a few copies of this work printed off, and it is now become scarce, and bears a considerable price. Dr. Smith possesses one copy, that originally in the library of Linnæus, and there is another in that of sir Joseph Banks.

An interesting little work, called "Insecta Musei Græ-

cenfis," from the pen of Nicolaus Poda, published in 1761, affords an account of the insects of Greece, arranged in the Linnæan manner. The same year an introductory work to the study of insects by J. H. Sulzer, was printed at Zurich; it is in quarto, with a number of plates, and bears the title of "Die Kennzeichen der Insekten durch 24 kupfer-tafeln erläutert, und mit derselben natürlichen geschichte begleitet." The same writer, in 1776, produced another publication also introductory to the science of insects, called "Abgekürzte geschichte der Insekten," illustrated with thirty-two coloured plates; which latter, with five or six additional plates, form the historical part of the quarto work published in Switzerland, in 1789, by J. J. Roemer, as an elucidation of the Linnæan and Fabrician systems. The title of the latter is "Genera Insectorum Linnæi et Fabricii iconibus illustrata." The outline of the Fabrician system, which this work contains, is conformable with that proposed in the earliest work of the last mentioned entomologist.

As a systematic production, the work of Geoffroy, printed at Paris in 1762, demands the particular attention of the modern entomologist. The work is entitled "Histoire abrégée des Insectes," and comprises all the insect tribes in the six following classes: 1st, coleopteres; 2d, hemipteres; 3d, tetrapteres à ailes farineuses; 4th, tetrapteres à ailes nues; 5th, dipteres; 6th, apteres. The first class corresponds with the Linnæan coleoptera; the second is more accurately regulated by the form of the proboscis; the third agrees with the lepidoptera, having the wings covered with fine powder; the naked-wing tribe unite the neuroptera and hymenoptera; the dipteres and apteres are the same with the Linnæan orders. It is a material distinction of this system, that the characters of the orders are determined chiefly by the number of joints in the feet; the general characters are taken from various parts of the body, wings, &c. The genera differ exceedingly in their construction from those of Linnæus, and many of them are in use to this day among the continental writers.

Brünniche is the author of two entomological tracts, printed about the same period, as, "Prodromus Insectologiae Siælandicæ," and an elementary work in Latin and Danish, called "Entomologia sistens Insectorum tabulas systematicas, cum introductione et iconibus." Sepp began his work, "Beschouwing der wonder gods in de minstgeachte schepzelen of Nederlandische Insecten," in the year 1762; it is dedicated entirely to the more uncommon moths and butterflies of Holland; the text is in the Dutch language, and the plates, which are not numerous, are admired for their peculiar neatness, being engraven in the dot or stipple style, with considerable delicacy.

This elaborate kind of engraving was in great esteem about the period adverted to, as appears from the encomiums bestowed on the plates executed by the hand of Lyonet, for his laborious work, "Traité Anatomique de la Chenille," printed in Holland the same year. This work of Lyonet is a treatise dedicated solely to the anatomy of the caterpillar, which lives in the wood of the willow, (phalæna cossus,) upon the dissection of which this author enters with such minuteness of investigation, that his descriptions of this object alone occupy rather more than six hundred quarto pages. The plates, eighteen in number, with the exception of the first, which represents the microscope employed in his examinations, are entirely appropriated to the representations of the muscles, tendons, fibres, medullary vessels, spiracles, &c. every part of which throughout the whole animal are exhibited in their natural and magnified appearance. These plates, as before intimated, are finished specimens of the stipple style of engraving then prevalent, and which,

which, from the closeness of its texture, nearly resembles mezzotinto.

Lyonet is said to have left at his death two manuscripts on the subject of entomology, neither of which have, to our knowledge, appeared before the world. One of these is inscribed "Œuvres Mêlées sur les Insectes," and contains his observations on the insects found in the environs of the Hague, where he resided. The other, an "Essai Anatomique sur la Chrysalide et la Phalène qui range le bois de saule," a work on the same plan, and forming a continuation of the history of the same insect, as his former essay on the caterpillar. This unpublished work on the chrysalis and fly was to be accompanied by no less than fifty-four plates, all the drawings of which were executed, and some of the plates engraved, previously to the death of the author, which happened, at an advanced age, in 1789.

The science derived some improvement from the various publications of Schæffer between the years 1764 and 1777. He produced, among others, an elementary work in German, "Zweifel und Schwürigkeiten, welche in der Insectenlehre annoch vorwalten," and another, entitled "Elementa Entomologica," containing no less than 132 plates, appropriated to the illustration of the principles of his system; and an additional section with two more plates, describing the various apparatus for catching, and the manner of feeding insects, microscopes for examining them, &c. "Vierter abschnitt von den Werkzeugen der Behandlung und Sammlung der Insecten." The most important of Schæffer's works, is that entitled "Icones Insectorum circa Ratisbonam indigenorum," comprised in three volumes 4to. with a vast number of coloured plates, the latter of which possess a character of great peculiarity in having two impressions on every print, one on the front of the leaf as usual, and the other on the back; by which means the plates are comprised in half the number of leaves they would otherwise occupy. The classification of Schæffer differs extremely from that of Linnæus; it approaches that proposed by Geoffroy, from which, however, it is still so far distinct, that being a system in some repute, it may not be amiss to present an outline of it in this place.

Schæffer divides all insects into seven classes, in the following manner:

1. Insecta coleoptero-macroptera, insects whose elytra are crustaceous throughout their whole length, and extend beyond the abdomen when closed.
2. Insecta coleoptero-microptera, differ from the former only in having the wing-cases shorter than the abdomen.
3. Insecta coleoptero-hymenoptera, or hemiptera, such as have the elytra half crustaceous, or becoming membranaceous towards their extremity.
4. Insecta hymeno-lepidoptera, or having wings imbricated with scales.
5. Insecta hymeno-gymnoptera, or with naked and membranaceous wings, comprehending the two Linnæan orders neuroptera and hymenoptera.
6. Insecta diptera, or insects having two wings.
7. Insecta aptera, or without wings.

The second part of "Zoophylacium Gronovianum," by Laur. Theod. Gronovius, contains the description of about six hundred insects with synonyms after the Linnæan manner, accompanied by four illustrative plates. The work is in folio, and was printed at Leyden in 1764.

Seba, in his splendid folio work, "Thesaurus Naturæ," published at Amsterdam in 1765, describes a number of the larger kinds of extra European insects, with figures executed with great force, and in a style corresponding with the other plates of his work.

VOL. XIII.

In 1769, Berkenhout published the first edition of his "Outlines of Natural History of Britain;" since which time two other editions of the same work have appeared. That portion of the work which is devoted to entomology includes a small selection of the species most conspicuous for their size, under each of the Linnæan genera, the insects being arranged throughout in the order of that system. The number of insects described amount to about six hundred. The work is destitute of figures.

Among the number of exotic insects figured in the plates of "The History of Birds," and the "Gleanings," by George Edwards, some are interesting from their beauty. There are a few also remarkable for their rarity, particularly scarabæus atlas, one of the three larger "Indian beetles;" libellula chinensis, called "the green-winged libellula;" and the larva or pupa of an extraordinary gibbous kind of locust, represented only, we believe, in this work. Insects were not sparingly introduced, notwithstanding that they were considered only as ornamental objects, the work being devoted principally to ornithology. In the course of the whole of this voluminous production, more than fifty species of the insect tribes are noticed, the greater part of which are butterflies. Edwards began this publication in 1743, from which period it was continued progressively till 1764. The catalogue was published in 1770, and forms part of the tracts entitled "Edwards on Natural History."

John Reinhold Forster, one of the eminent naturalists who accompanied the celebrated Capt. Cook in his voyage round the world, has left us a catalogue of British insects printed in 1770. It is only a list of Latin names of a certain number of species, and was intended as a prelude to the copious work on the insects of this country, which its author intended to write. This catalogue, however, and his "Novæ Insectorum Centuriæ," which appeared in London the year after, are the only entomological works that author published. Of the latter we ought to speak more at large. The avowed purpose of this little book, as the reader is informed in the preface, was to give a description of one hundred insects not mentioned in the latest work of the illustrious Linnæus. The insects included are partly indigenous, some are from China, and others from South America. The greater number of these are coleopterous insects, and are arranged after the manner of Linnæus, though the genera anthribus and cistela are taken from Geoffroy. It may be lastly observed, that although these insects do really appear to be undescribed by Linnæus, some few of them were previously made known to the world by the works of Schæffer and Drury. This its author was aware of, but as they had escaped the observation of the author, whose work he was solicitous to improve, it was still considered right to introduce them.

The first volume of the "Illustrations of Natural History, wherein are exhibited figures of exotic insects," &c. by D. Drury, was published in 1770. The plates, fifty in number, form a miscellaneous assemblage of the more beautiful extra European insects, which the extensive collection of its author afforded. The second volume was produced three years after the first; and the third, which concludes the work, so far as the author proceeded with the publication, appeared in 1782. Besides the insects represented in these volumes, the extensive cabinet of the author contained many very choice specimens, reserved as materials for the fourth volume which was in contemplation; and among the rest, a number of curious species collected in the interior of Africa, and other countries rarely visited by Europeans, the introduction of which would have rendered the fourth volume of much greater interest to the entomologist than

H h either

either of the preceding; this may be collected from the manuscripts of Mr. Drury, in the possession of the writer of this article, and which are now before us. From an inspection of these papers, it likewise appears, that the author intended, in a revival of his former volumes, to have assigned the Fabrician names to all the insects contained, so far as these could be obtained, and that for this purpose Fabricius had himself furnished Mr. Drury with a number of names and references, independently of those which had been published in his "Species Insectorum," a paper by Sebastiani, "Insecta ad aquas Mattiacas super nive deprehensa," bears the same date with Drury's first volume of exotic insects, and as nearly as we can ascertain Kahn was about this very period engaged at Berlin in his publication "Anecdoten zur Insekten-geschichte," a work written in German, and published in numbers. The tract of Kahn, relative to the mode of catching and preserving insects, called "Kurze Anleitung Insekten zu sammeln," is dated 1773.

The "Institutions of Entomology," by Thomas Pattinton Yeats, is the only production of its unfortunate author relative to this subject: it is a translation of the Linnæan orders and genera, collated with three other systems, namely, those of Geoffroy, Schæffer, and Scopoli, together with observations by the translator. This was a valuable book at the time of its production. In the present day it is become rather obsolete; and it is in particular defective in the comparison drawn between the Linnæan system and that of Scopoli; not from any error of the translator, but an event that could not be anticipated. Scopoli coincided nearly with Linnæus in his arrangement of insects, when he wrote his "Entomologia Carniolica;" after which, however, he abandoned that method, and adopted another; that which has since obtained currency on the continent under the name of "Scopoli's System." This last mentioned work was not printed till four years after the translation by Yeats.

"The Aurelian's Pocket Companion," by Moses Harris, is a kind of alphabetical catalogue of the larger butterflies, sphinges, and moths collected in England by its author: a tract of no utility to the naturalist, unless he first condescends to become an adept in the jargon of the aurelian, or, as now termed, the entomological society; the insects being throughout designated by the silly names imposed by the few illiterate persons associated under this denomination. In this English lexicon of entomology, we have "The Wall," "The Bank," "The Turnpike-gate Keeper," "Ghost," "Old Woman," "Dish-clout," and a vast number of others equally capricious and replete with absurdity.

J. C. Fabricius, the indisputable founder of a new system of entomology, published in the year 1775, his "Systema Entomologica," in which the principles of his novel mode of classification is for the first time developed. The essential characters of the classes are determined from the organs of manducation, or mouth (instrumenta cibaria). In this work insects of every description are comprehended in eight classes to which the several names of eleutherata, ulonata, fynestata, agonata, ungonata, glossata, rhingota, and anti-liata, are assigned.

This work obtained for its author very high reputation, and such further inducements to the prosecution of his entomological studies, that in the course of a few years after several other works appeared from his pen on the same subject, among which were his "Species Insectorum," "Entomologia Systematica," &c. in all which his original manner of classification was adopted with progressive improvement. His "Supplementum Entomologiæ Systematicæ," presents an outline of his system in its latest state, and is the basis on which the last work in which he was engaged, his

"Systema Eleutheratorum" was undertaken. Part only of this valuable work has hitherto appeared, its completion being impeded, if not finally interrupted, through the death of the author; but so far as he did proceed, the arrangement proposed in his supplement is adopted, and we cannot entertain any other conclusion than that it would have been acceded to throughout. This may hence be admitted as the best he had formed in the opinion of its author, and a conclusion, the result of so much extensive knowledge in the science as Fabricius possessed, deserves our serious consideration.

In this system Fabricius distributes all insects into thirteen classes, the characters of which are as follow:

Class 1. *Eleutherata*. Jaws bare, free, and bearing feelers.

2. *Ulonata*. Jaws covered by an obtuse mouth-piece

3. *Synistata*. Jaws elbowed near the base, and connected to the lower lip.

4. *Piezata*. Jaws horny, compressed, and usually elongated.

5. *Odonata*. Jaws horny, dentated; palpi two.

6. *Mitofata*. Jaws horny, vaulted; no palpi.

7. *Unogata*. Jaws horny, unguiculated.

8. *Polygnata*. Jaws several (usually two) within the lip.

9. *Kleislagantha*. Jaws several, outside the lip.

10. *Exochnata*. Jaws several, outside the lip, and covered by the palpi.

11. *Glossata*. Mouth composed of a spiral tongue, situated between two palpi.

12. *Rhyngota*. Mouth composed of a beak or articulated sheath.

13. *Antliata*. Mouth composed of a sucker, not articulated.

This able entomologist is the author of various tracts on entomology, written in the Latin and German languages; and also of two principal introductory works, "Genera Insectorum," and "Philosophia Entomologia."

The insects of Switzerland are described by J. C. Fueslin, in an interesting little work, to which its author gives the title "Verzeichnis der ihm bekannten Schweizerischen Insekten," printed at Zurich, and bearing the same date (1775) with the Fabrician "Systema Entomologica."

The number of insects figured in the "New Illustrations of Zoology," by Peter Brown, in 1776, is by no means considerable; some few of which it does contain are nevertheless sufficiently important in point of rarity to deserve explicit mention. The purple-winged locust is, in particular, a magnificent insect: at the time this artist made his drawing, the specimen, which is presumed to be unique, was in the possession of Mr. Tunstal; at present it enriches the splendid collection of Mr. Macleay. The work of Stoll, it should be observed, affords likewise a figure of this species, and which, it is believed, was taken from the same specimen previously to its being purchased in Holland for Mr. Tunstal.

The extensive systematic work of J. A. E. Goeze, called "Entomologische beyträge zu des Ritter Linné zwölften aufgabe des Natur systems," began to be published at Leipzig in 1777, and was continued progressively in parts till 1783. In the same year, with the commencement of this publication, Esper produced in Germany the first part of his useful book on the lepidopterous tribe of insects, "Die Schmetterling in Abbildung nach der natur mit beschreibungen," a work with many plates, and of which a second part was published in 1779. Between that time and 1786 two other parts appeared likewise, and which altogether form

a very extensive publication. Two other very costly works, devoted exclusively to this beautiful order of insects, were also begun in 1779, one at Paris in the French language; the other in Holland, and in the language of that country: the first of these is entirely appropriated to the insects of Europe, and is named "Papillons d'Europe, peints d'après nature;" the latter is by Pieter Cramer, and consists of the extra European species. The title of this work is, "De uitlandsche kapellen, voorkomende in de drie waereld deelen Asia, Africa, en America," and including the continuation published about the year 1782, consists of four volumes quarto, with many plates. The production of these expensive works sufficiently demonstrates the encouragement bestowed on the subject of entomology upon the continent of Europe.

An elementary work by James Barbut, bearing the title of "The Genera Insectorum of Linnæus, exemplified by various specimens of English Insects," was published in London in 1781; and which, besides the text, contains altogether about twenty-two plates, two of which are explanatory, and the rest comprehend indifferent figures of a small number of species in each genera. As an illustration of the Linnæan system, this work may be in some respects useful to the English reader: its views are too limited to admit of more general utility. The author does not seem to be aware of the improvements the science had undergone upon the continent, in the interval between the publication of the "Genera Insectorum" of Linnæus, and the time in which he wrote, and has not therefore drawn those comparisons between them, which, without innovation on either, could not fail to have placed the science in a more lucid point of view. It is, indeed, to the silence of English writers in this respect, generally arising either from the want of information, from sentiments of illiberality, or from negligence, that we must ascribe the very low state of entomological knowledge in Britain, even to the present period. Francisus de Paula Schrank distinguished himself by his enumeration of the insects of Austria in 1781, written in Latin, "Enumeratio Insectorum Aultriæ indigenorum," afterwards rendered into German by Fuefsly. The same year John Nepomuk von Laicharting published at Zurich his catalogue of the insects of the Tyrol, "Verzeichniß und beschreibung der Tyroler Insecten," a second part of which appeared in 1784. Laicharting adopts a system somewhat different from that of Linnæus; he divides insects into ten classes, characterized from various parts of the body. His classes are scarabeides, grylloides, cimicoïdes, papilionoides, libelluloïdes, vespoides, muscoïdes, cancröïdes, aranoïdes, and oniscoïdes. In 1782, a paper by Morand was published in the Transactions of the Paris Academy, entitled "Memoire sur les vers de Truffes, et sur les mouches qui en proviennent." A small octavo by J. S. Semler, in the German language, bears the same date, and is worthy of attention, "Versuch eines Diarium über die Oeconomie mancher Insecten im Winter," and there is besides this another more extensive book printed in 1783, relative to the aphides, called "Nachlese zur Bonnetischen Insektologie." A catalogue of lepidopteræ, written by Lang in the German language, came out in the same year. And, lastly, a "Short history of the brown tail Moth," by W. Curtis. The caterpillars of this moth, it may be recollected by many readers, appeared in such immense swarms in the fields surrounding London during the summer of 1782, and from their ravages despoiled so many trees of their foliage, as to create very serious apprehensions of approaching destruction to the whole vegetable tribe. The object of this pamphlet was to prove that graminiferous plants, not being the natural food of these voracious vermin,

would escape their attack. This circumstance alone will serve to testify, that some benefit at least may result from an acquaintance with the science of insects. Its author was by this means enabled to dispel the uneasiness occasioned through the appearance of these suppoled ministers of famine; and which prevailed to such an alarming extent throughout the whole population of this vast metropolis, that prayers were ordered to be read in all the churches to avert the impending calamity.

An elementary work by J. A. B. Bergstræffer, a small octavo, entitled "Entomologia, scholarum in usus concinnata," was published in 1784; this author had previously distinguished himself by his German work, entitled "Nomenclatur und beschreibung der Insecten in der Grafschaft Hanau-Müntzenberg," &c.

The entomological tracts published about this period, and rather earlier by Thunberg, contributed to promote this science; his dissertations, named "Novæ Insectorum," of which several appeared between 1781, and ten years after; and also his "Dissertatio sistens Insecta Suecica," the first of which occurs in 1784, are interesting. The relation of his travels to the East abounds with information respecting natural history, and relates in some degree to entomology; and he also produced a curious memoir on the pausif genus, called "Beskrifning poa tuänne nya Insecter," besides other tracts in the Swedish and Latin languages.

Retzius, in 1783, produced his "Genera et Species Insectorum," in which the method of Degeer is simplified, and the Linnæan terminology adapted to that performance. Insects, according to this system, are divided into fourteen classes; namely, lepidoptera, alingua, neuroptera, hymenoptera, siphonata, dermaptera, hemiptera, coleoptera, halterata, proboscidea, suctoria, ancenata, atrachelia, and crustacea.

Harrer wrote on the insects of Germany, in a small book printed in 1784. The year after Jabloniky began the important systematical work, called "Natur system aller bekannter in-und ausländischen Insecken," printed at Berlin; about the same time Fourcroy published his catalogue of the insects found in the neighbourhood of Paris in Latin, under the title of "Entomologia Parisiensis;" and another illustration of the elements of entomology, written in German, appeared at Leipzig from the pen of Schmiedlein. Some African insects, that inhabit the Cape of Good Hope, were described in 1786 by Xavier Walfen; and two publications on the lepidopteræ of Germany, and both written in the language of that country, came out in the same year, one by W. Gefenius, the other bearing the title of "Beitrag zur geschichte der Schmetterlinge," and printed at Augsborg, is by Hübnær.

The insects of Naples are described by Dominicus Cyrellus in a folio work published in 1787, called "Entomologie Neapolitanæ." A curious and useful little tract on the oestrus, or gad-fly genus, was the same year printed at Leipzig by J. S. Fischer under the title of "Observationes de Oestroovino atque bovino factæ," to which a copious appendix was annexed in 1788. The cochineal insects discovered at Madras some few years before, gave rise to a series of letters on this important subject, by James Anderson, addressed from Madras to sir Joseph Banks, fourteen of which were printed together in that country in the year 1788; there are, besides these, two other letters which have been published since, also a separate publication by the same author, containing an account of the importation of American cochineal insects into Hindoostan. Swederus, in 1788, published a monograph on that curious coleopterous genus

## ENTOMOLOGY.

terapterus, in a memoir entitled "Beskrifning poa ett nytt genus ibland insecterna, hörande til Coleoptera."

The science of entomology obtained some further advantages about this period, from the publication of the enlarged edition of the Linnæan "Systema Naturæ," by J. F. Gmelin; not from possessing in itself any peculiar merit, but because as a general, and therefore useful work, it combines much valuable information, compiled from the labours of various naturalists of the first consequence since the time of Linnæus. In the entomological part, consisting of three volumes, published at Leiptic in 1788, the editor is considerably indebted to the writings of Fabricius; for although he rejects his mode of classification, his orders, and most of his genera, he has copied no inconsiderable portion of his new species, and by that means very materially augmented and improved the original work of Linnæus. Besides this, the pleasing works of Stoll contributed about this time to facilitate the study of the hemipterous order of insects, from affording figures of many extraordinary species of the locust, fulgora, cicada, cimex, and other tribes, extant in the various continental cabinets at that time, and, among others, that of the prince of Orange. His first work is called "Natuurlykkye af beeldingen en beschryvingen der Cicaden in alle vier waerelds deelen." The two published since are only a continuation, including other genera besides the cicadæ, as the locustæ, phasmæ, &c. These works were printed at Amsterdam. The work of M. B. Borkhausen, written in the German language, relates entirely to European insects of the lepidoptera kind, and bears the title of "Naturgeschichte der Europäischen Schmetterlinge nach Systematischer Ordnung." The first part appeared at Franckfort in 1788; and since that time the work has been considerably extended. The article entomology, inserted in Hall's Encyclopædia, as it appeared originally in 1788, was written by Marsham, and is exemplified by three plates; and about the same time, Roemer published in Switzerland his "Genera Insectorum Linnæi et Fabricii iconibus illustrata," including thirty-seven explanatory plates, nearly all of which, however, had previously constituted the work of Sulzer.

Immediately after this, the publication of one of the most voluminous works on entomology that has been attempted was undertaken at Paris, by G. A. Olivier. Its title is concisely "Entomologie, ou Histoire naturelle des Insectes;" from which we may infer, that its author proposed to have treated on every class and order, and, in conformity with the first part, to have accompanied the whole with figures. Several fasciculi or numbers were published, amounting altogether to about three volumes; the whole of which are confined to the order coleoptera, and that even remains very incomplete. So far as it does proceed, the work is valuable. Olivier is the author of several other entomological writings. In the "Journal d'Histoire Naturelle," he has a memoir, "Sur l'Utilité de l'étude des Insectes, relativement à l'Agriculture et aux Arts." He is also the proposer of a methodical division of insects, in the "Dictionnaire Entomologique." According to this plan, insects are to be divided into four parts, namely, 1. Insects with four wings; 2. Insects with two wings and two wing-cafes; 3. Insects with two wings; 4. Insects without wings in either sex. These are subdivided into eight orders, the characters of which are taken from the mouth.

The insects of Europe were further described by C. de Villers, in a small work published at Lyons, in 1789, under the title of "Linnæi Entomologia," &c.; in which he professes to avail himself of the works of Scopoli, Geoffroy, Degeer, Fabricius, and others. Paykull was at this time

engaged also upon the insects of Sweden, at least on the coleoptera; and this year he published his "Monographia Staphylinorum Suecicæ;" and which, a while after, was succeeded by two other tracts on the curculiones and the carabi, "Monographia Curculionum Suecicæ;" and "Monographia Caraborum Suecicæ." But the most extensive of the works of Paykull is his "Fauna Suecica," in three octavo volumes, printed at Upsal in 1799.

In the "Journal für die Entomologie," the name of Meyer occurs as the author of some remarks on the melonlontha. Preyler, in the year 1790, published at Prague a "Verzeichniß," or catalogue of the insects of Bohemia. Quenfel is the author of a tract on the papilio, entitled, "Beskrifningar öfer 8 nya Svenska Dagsjärillar;" and also of another on noctua pruni, "Beskrifning öfer en y Natfjäril."

The first part of a considerable work, "The Natural History of British Insects by E. Donovan," appeared in the early part of the year 1792; and having obtained a favourable reception, has been continued in a course of monthly numbers from that period to the present time (1800). The design of this undertaking is to afford scientific and general descriptions, accompanied by appropriate coloured figures of every insect discovered in this country; and so far as that desirable object could be accomplished, in all their various states of transformation. In its present form, the work consists of fifteen volumes; the number of plates exceed 500, and these include an extensive variety of species. Without incurring the charge of presumption, the writer of this article believes he may be allowed to observe that the present constitutes the most copious work of its kind that has hitherto, or probably ever may be undertaken, as an elucidation of the entomology of Britain.

The insects of Germany afforded materials for another entomological work of a local nature, commenced by Dr. G. W. F. Panzer, in 1793, under the title of "Fauna Insectorum Initia, oder Deutschlands Insecten;" and this was shortly after succeeded by his "Entomologia Germanica," &c.; both which are written in German and Latin, and are illustrated by plates. Dr. Smith's "Tour on the Continent: in 1786-7," was published also in 1793; and this claims our particular mention, as it will be found to contain some curious observations respecting the insects of the countries he visited. About the same time, a French edition of Fuesly's "Archiv der Insektengeschichte" made its appearance in quarto, with the original plates.

A valuable systematic paper, proposing "a new arrangement of the papilios" by Mr. William Jones, occurs in the second volume of the Transactions of the Linnæan Society, printed at London in 1794. The object of this communication is to point out, that the shape of the wings, which form a principal character with Linnæus in his distribution of this genus into families, though various at the first view, approach each other so gradually, that it is impossible to draw from them the distinguishing line between each family. The number of species known to Linnæus are estimated at rather more than 274, whereas the writer observes he had seen above 1000 in various cabinets, and about 400 more represented in various publications; and from an attentive examination of these is induced to offer the following amendments to the characters of each family, as defined by Linnæus. The latter author describes the *Equites* as having "the upper wings longer from the posterior angle to the point than to the base; and the antennæ often filiform:" this is corrected by saying, "the upper wings are longer from the posterior angle to the point than to the base, occasioned by having four nerves instead of three, visible in

every other family. The palpi frequently only a brush; under wings, with a connecting nerve in the centre, and without an abdominal groove."—*Heliconii*. "Wings narrow, entire, often naked, or deprived of scales; the upper wings long, the inferior short." Linn. To this character is added, that the upper wings have "a connecting nerve in the centre, very slightly grooved to admit the abdomen, which is in general long, as are also the antennæ."—*Danai*. "Wings entire." Linn. Addition: "the under with a connecting nerve in the centre, and a deep abdominal groove; palpi projecting."—*Nymphales*. "Wings denticulated." Linn. Addition: "the under without a connecting nerve in the centre, and with a deep abdominal groove; palpi projected."—*Plebeii*. "Small, rurales; spots on the wings obscure." Linn. Addition: "thorax and abdomen slender; under wings without a connecting nerve; antennæ clubbed;" and these are divided into two sections, those with long, weak, flexible tails; and those without tails, and having the wings entire.—*Plebeii urbicola*. "Spots on the wings for the most part transparent." Linn. These Mr. Jones divides into three families, according to the following character. \* Thorax and abdomen short, thick, or broad; under wings without a connecting nerve; antennæ uncinated, or crooked at the extremity. \*\* With upper wings pointed at the extremity, and long in proportion to their width. \*\*\* Upper wings less extended, and together with their under wings more rotund; their margins entire. There still remain some papiliones, which do not rank with any division above mentioned: these are generally of a large size, without an abdominal groove; have no connecting nerve; their antennæ generally acuminate; and the veins of both upper and under wings extending from their root to the extremity nearly in straight lines. The author of this paper constitutes these as a new family, under the name of romani.

We ought not to dismiss our abstract of the above paper, without observing that, from the great attention bestowed on the papiliones by Mr. Jones, his opinion is of unquestionable authority. The species, which it is intimated the writer has seen in various cabinets to the amount of 1000, or perhaps more, have not to our own knowledge been observed merely: Mr. Jones has taken the trouble, for the gratification of himself and his scientific friends, to paint every species, and that in a very correct and elegant manner. The collection of drawings thus formed affords an unparalleled display of this beautiful tribe of insects.

In 1795, "The Papilios of Great Britain," a quarto work with plates, by William Lewin, was published in London. Whether it was the intention of the author to have proceeded further with this publication is uncertain: it finally terminated with the completion of the butterflies. About the same period the coleopterous insects of Sweden were published in the language of that country, by D. E. Næczén, some part of whose works had, however, been produced to the public before that period. His books (for there are two) are entitled "Befkrifning poa noagra, vid Umeoa fundene okände arter ibland Skalbaggarne," and "Befkrifning poa noagra vid Umeoa fundne Insecter, dels okände, dels foort utydiligen bemarkte och Fauna Suecica ej uptagne." A Latin tract, printed in 1795, by D. H. Hoppe, contains an enumeration of the coleopterous insects found in the environs of Erlang, in Franconia; and in the same year, Latreille published his work, entitled, "Précis du Caractère des Genres." In this last-mentioned work, insects are divided into two principal classes, namely, those with wings, and those without wings. The orders are coleoptères, orthoptères, hémiptères, neuroptères,

lépidoptères, suceurs; thysanoures; parasites; acéphales, entomostracés, crustacés, and myriapodes. An arrangement of the insect tribes, in a manner somewhat different, occurs in "Tableau Methodique des Insectes," by the same author. An important paper on the oestrus genus, by B. Clark, inserted in the third volume of the Linnæan Society Transactions, is duly noticed under the article Bor. The last production we have to mention in the present year is a small tract, accompanied by a coloured figure of an extremely beautiful and singularly formed beetle, in the cabinet of Mr. Francillon; a species of scarabæus, having the posterior legs remarkable both for their length and thickness, and hence denominated the kangaroo beetle (*scarabæus macropus*). The insect is presumed to be a native of Potosi, in South America.

The second volume of "Catalogus Bibliothecæ Historico Naturalis, Josephi Bauks baroneti," &c. by J. Dryander, comprehending the entomological works of that invaluable library, issued from the press in 1796. From the classic manner in which each production is arranged in an appropriate department, according to its leading character, this work must be considered as forming in itself a valuable bibliothecal system of entomological writers. As an assemblage of references, we cannot speak too highly of its contents.

"The Natural History of the rarer Lepidopterous Insects of Georgia," in North America, forms a pleasing accession to our knowledge of those particular species which it is the object of this work to elucidate. The number of insects contained in the two costly volumes, of which the work consists, amounts to about one hundred. These constitute an ample selection of the larger kinds of the butterfly, sphinx, and moth tribes, peculiar to that region. Each insect is represented with its larva, pupa, and an example of one of the plants on which it is known to subsist. This work is written by Dr. J. E. Smith, from a series of notes and drawings made by Mr. Abbot, an assiduous collector in North America; and besides combining the practical information derived from the latter source, is rendered valuable by the numerous additional observations of the author. This work appeared in 1797.

Clairville, the author of a work on the insects of Switzerland, published in 1798, proposes to divide insects into eight orders, somewhat after the manner of Linnæus, but to distinguish them under other names, and to denominate them classes instead of orders. The names he proposes are elyptopteres, dictyoptères, thleoptères, halteroptères, lepidopteres, héminéoptères, rophoptères, and pododunères.

In the same year with the preceding, "Donovan's Natural History of the Insects of China" appeared in London. This is the only work dedicated to the display of the entomological productions of that vast empire that has been published. The materials which constitute the basis of this volume, and from which it was in a great measure composed, were obtained from the first and most authentic sources; including examples of the insects collected at the time of the embassy of lord Macartney, in addition to many others obtained from various cabinets of the highest celebrity, and the communications of friends. The work is embellished with fifty coloured plates. A translation of this publication has appeared on the continent in the French, and another in the German language.

The year 1800 was productive of several valuable works on the subject of entomology; in Sweden, Paykull this year published his "Fauna Suecica," a much-admired publication, in three volumes octavo. Cuvier, with the assistance of

Duméril,

Duméril, brought forward in Paris his celebrated "Anatomie Comparée," a work which, however ill suited to the philosophic taste of our own country, is a production of very extraordinary merit. The organization of the various tribes of insects is treated at great length in the lectures relating to invertebral animals. This work affords us also a new systematical arrangement, in which all insects are divided into two principal sections; those with jaws, and those without jaws. In the first of these orders are comprehended the gnathoptères, neuroptères, hymenoptères, coleoptères, and orthoptères; the second, consisting of such as are destitute of jaws, are, hemiptères, lepidoptères, diptères, and aptères. The fifth volume of "Bibl. Hist. Nat. Banksiana," the addenda of which contains some further mention of entomological writers, was also published in 1800. The last work that appeared in the present year was "Donovan's Insects of India," a publication corresponding in size, and style of embellishment, with the "Insects of China," and, like that work, embracing in a general, though scientific view, a comprehensive display of the more curious, rare, and splendid species peculiar to those fertile regions, the entomology of which it is designed to explain. This work, as in the former instance, is constituted from the first sources of original information. The more immediate intention is the elucidation of the entomological production of the British possessions in India; but it contains also a variety of insects of the more beautiful kinds discovered in the interior of that vast continent, and in the islands situated in the Indian seas.

Lamarck's "Système des Animaux sans Vertèbres," printed at Paris in the 9th year of the revolution (1801), presents a new mode of arrangement for insects. These its author proposes to divide into three primary classes; namely, 1st, those with mandibles and jaws; 2d, those with mandibles and a kind of trunk; 3d, those without mandibles, but having a trunk or sucker. The first of these classes contains the coleoptères, orthoptères, and neuroptères; the second is confined to the single order hymenoptères; and the third includes the lepidoptères, hemiptères, diptères, and aptères. The coleopteræ are sub-divided into three families, according to the number of joints in the feet, as those with five joints in all the feet; those with five joints in each the four anterior feet, and four in those of the posterior pair; and those with only three joints in all the feet. Most of the Linnæan aptera are removed to another class preceding the insect tribe; the only Linnæan genus of aptera, admitted by Lamarck into his order aptères, is the pulex.

The publication of "Marsham's Entomologia Britannica" commenced in the year 1802, with the production of the volume in which the coleopteræ are described. As the outline of the arrangement adopted by this author is strictly Linnæan, those after the manner of that naturalist constitute the first series, and are to be succeeded progressively by the hemiptera, lepidoptera, and other remaining tribes. For the purpose of this continuation very ample materials are provided. Mr. Marsham, whose abilities as an entomologist are well known, has devoted many years of his life to this laudable object: his collection of British insects is of the first class, and his manuscripts of the most valuable kind. The completion of this work must be therefore anticipated as a desirable event. The merit of the first volume is acknowledged, and should the future part appear with corresponding excellence, we could not hesitate in pronouncing it one of the most important works of its kind that has appeared.

Kirby's "Apum Angliæ" was also printed in 1802. This

work contains much curious information relative to the bees of this country; a path of entomology in which its ingenious author has trod with great success. The Linnæan genus apis Mr. Kirby conceives it necessary to divide into two genera, to one of which he retained the original name, the other he terms melitta, and under both genera he describes many species, some of which are noticed for the first time in this interesting work. Latreille, who has written on the Linnæan genus apis, and is esteemed an entomologist of ability, pronounces this "un bon travail." The ninth volume of the Transactions of the Linnæan Society contains an ingenious paper on the apian genus of Herbst by Kirby; and there are also two or three other papers dispersed in those volumes, by the same writer, well deserving of attention.

The contents of the second and third volumes of Turton's translation of the Linnæan "Système Naturæ à Gmelin," relate entirely to entomology. This work deserves further observation. The editor does not, in treating of insects, confine himself to the direct translation of his author; he introduces some commendable improvements in the arrangement after the Fabrician manner; and he besides incorporates from other entomological works of credit, published since the time of Gmelin, whatever prominent traits of information he conceived calculated to amend the original work. We may easily perceive that Dr. Turton has availed himself of the Fabrician "Entomologia Systematica" to a greater extent than Gmelin, and has by this means rendered more essential service to the English reader.

The pages of "Donovan's Tour through South Wales and Monmouthshire," lately published, are interspersed with observations on the various natural productions of the interesting tract of country immediately under consideration. Those digressions, from objects of more general moment, if such the reader be inclined to deem them, we at least may presume to think important; and so far as these relate to the science of entomology in particular, conceive they may, without impropriety, be adverted to in this place.

"Donovan's Insects of New Holland," including also those of New Zealand, New Guinea, and the several islands in the Great Southern and Pacific ocean: this accords with the "Insects of India," already mentioned, being in quarto, with scientific and general descriptions, and in having the similar accompaniments of accurately coloured plates. Of this work it will be alone sufficient to observe, that through the distinguished favour bestowed on the design, the author was allowed to enrich his volume with delineations of those uncommon insects collected during the voyage of captain Cook, by those celebrated naturalists who accompanied that circumnavigator round the world, and which appear for the first time in this work.

The sixth volume of "Shaw's General Zoology" is offered as an illustration of the science of entomology. The work professes only to elucidate the Linnæan genera of insects, with the history of the principal species. This being the intention of its ingenious author, the work is comprized in a very moderate compass. The plates are rather numerous, and in general remarkable for the neatness of engraving. These, however, are not original, being compiled from the plates of Seba, Rosel, Swammerdam, Barbut, and others. The "Naturalist's Miscellany" contains a variety of coloured figures of the more splendid kinds of exotic insects, with descriptions extremely suitable to the general class of readers, for whose purpose they are designed.

Lastly, we ought to mention the work of Coquebert, entitled "Illustratio iconographia," recently published in France: the late entomological tracts of Olivier and La-

treille, the "Faune Parisienne" of Waleknaer, and the papers on different tribes of insects inserted in the Transactions of the Linnæan Society of London; the Société d'Histoire Naturelle of Paris, and those of various other learned institutions, through the medium of which they are distributed to public observation.

Our review of entomological writings is at length drawn to conclusion. In its progress we have endeavoured to include every work of importance in this department of science, that has appeared. To what has been advanced respecting these, nothing material can be added in this place; it was our aim, throughout the present inquiry, to point out the leading character of each work, while passing under immediate consideration, and for this reason we shall abstain from offering any general comments. By connecting the whole in the order of time in which they were produced, our object has been to show at one glance, so far at least as our slight comparisons would permit, those essential respects in which each has materially improved upon his predecessor; and by that means mark the progressive advancement made in the science with some precision. We shall finally dismiss this part of our subject with observing, that it is possible some few works of real worth may have escaped our mention; the number of these, however, we are persuaded, must be very inconsiderable, and confined to such as have recently appeared in countries remote from Britain.

*Classification.*

It will be observed, from the preceding observations, that naturalists entertain very distinct opinions as to the principles on which the classification of insects ought to be founded. This diversity of idea arises from the different views under which they have been considered. Valisneri divides insects into four classes, according to the places in which they live, as plants, in water, in the earth, or upon the bodies of other animals. Agricola into three, namely, those which walk, fly, and swim; Frenzius, into flying insects, aquatic insects, and terrestrial or creeping insects. Swammerdam distributes them into classes from their appearance in the states preceding their final transformation, without particular regard to the last or complete state. In this respect Swammerdam is followed by Ray, whose two primary classes are, of those which undergo transformation, and those which do not; and his orders are determined from their metamorphoses, and the number of their feet. Lister has given a system founded on the figure of the egg in which the insect is inclosed, and the number of the feet. The difference observable in the texture, and also in the number of the wings, form the distinctions of the primary divisions of Linnæus. And lastly, the principal characters upon which insects are distributed, in the arrangement of Fabricius, is taken from the structure of the mouth. Each of the systems founded on those dissimilar characters have gained admirers. The characters of the Linnæan and Fabrician systems appear the best, and are most universally approved.

*General observations on Insects.*

Insects are a race of animals destitute of internal bones, in which respect they accord with a very extensive number of natural families in the lower orders of animated beings. Their bodies are kept in a state of moisture by the circulation of lymphatic transparent juices instead of red blood, and in this particular agree with the worm tribe. They have no distinct heart, external ears, openings at the nose, or nostrils, nor teeth in the mouth; and some assert that

they are destitute of voice. An insect is divided into segments, or joints, and covered externally with a tough or bony skin, which is either naked or clothed with down. The head is furnished with moveable antennæ, and the body with feet.

These animals are destitute of visible external organs of breathing at the mouth, their respiration is performed through the lateral apertures, or spiracles of the body and thorax.

They have two eyes, in which respect they agree with the larger tribe of animals: they have no cycelids, and their eyes are rarely placed on a pedicle; the diophsis is an exception.

The antennæ are situated on the head before the eyes; and are composed of an indefinite number of articulations; in genuine insects, the antennæ never exceed two. The cancri have a greater number, and many of the Linnæan apteræ have none.

The feelers are articulated, moveable, variable in number from two to six, and are affixed contiguous to the mouth.

The mouth is usually situated beneath the head.

The jaws are disposed transversely in the head, and move laterally, by which means they are distinguished from most other animals.

The trunk is placed between the head and the abdomen.

The abdomen is usually annulated with five segments, and is sometimes armed at the end with a sting.

The legs are usually six in number, and are attached to the trunk. Each leg consists of three distinct divisions, the thigh, shank, and feet.

The wings are either two or four; some of those with two wings only are protected by a shelly covering, as in the coleoptera.

Insects are oviparous; deposit their eggs in an impregnated state in general, and do not brood over them, or their young. Most insects undergo a triple transformation, the egg producing a grub or larva, which becomes, when full grown, a pupa, and the later producing the perfect fly. The sexes are male and female; there are also neuters in some species devoted to labour for the former. Insects cast their skins, and therein agree with reptiles. They are said to inhabit those plants on which they usually feed.

*Description of the component parts of Insects.*

The external parts of which insects consist are divided into four principal sections, the head, trunk, abdomen, and members, each of which require to be separately considered.

*Caput, or Head.*—Under this term is included the first, or principal organ, the head, properly so denominated in its collective form. This part is supposed to be the principal seat of the senses, as in all others of the larger and apparently more perfect animals. Internally it contains the medullary substance or brain; its exterior characters are, the mouth, eyes, stemmata, antennæ, front, vertex, and throat.

In some insects the head is very large in comparison with their body. The proportion between the head and body is not the same in all insects, even in the different stages of growth or transformation. In the caterpillars, which have this part horny, it is generally small before they moult, or change their skin, and becomes larger after each moulting.

This part is almost constantly distinct from the thorax: in the coleoptera it is connected close to the latter: the hemiptera offer many examples in which the head is slightly attached, as in the genera blatta, acheta, phasma, mantis, &c.: in the lepidoptera order the head is not always very intimately situated to the thorax; there is a small interval sometimes between which the articulation of the neck may be

seen, when the head is inclined downward. The succeeding order, neuroptera, afford numberless instances of the head being placed upon a slender ligamentous pedicle at a distance from the thorax: in hymenoptera and diptera the head is rather remote, sometimes being placed on a small tubercle in the anterior part of the thorax; and in the last, or apterous order of Linnæan insects, several of the genera are distinguished by having the head and thorax confounded with each other, as in scorio, aranea, monoculus, &c.

The connection between the head and thorax in insects subsists by one of two modes of articulation; the first, in which the point of contact is solid, and the motion depends upon the shape of this part, or another in which the articulation is formed by a ligament. In the articulation of the head by the contact of the solid parts, the head has commonly, at the part answering to the neck, one or two smooth tubercles, which are received into correspondent cavities on the anterior part of the thorax. This is exemplified in the genera scarabæus, lucanus, cerambyx, and most other coleoptera, and which hence have the power of moving the head backward or forward, and thus of directing the mouth downward. Another mode of solid articulation takes place when the posterior part of the head is rounded, and turns on its axis in a correspondent socket on the anterior part of the thorax, as in the brentus, &c. The axis of motion is then in the centre of the joint, and the mouth of the insect can be directed either upward or downward, or to the right and left. A third sort of articulation occurs when the head is truncated behind, and joins by a flat surface either to a tubercle of the thorax or to another flat and corresponding surface, as is seen in many of the hymenoptera and diptera. In some kinds of the Fabrician attelabi, this solid articulation is accomplished by another means: the head of these insects terminate behind in a round tubercle, which is received into a correspondent cavity of the thorax: the inferior edge of this cavity is notched, and thus confines the motion of the head to one direction.

The ligamentous connection of the head and thorax is shewn in the blatta, forficula, mantis, and several of the neuroptera. In this mode of articulation, the motion of the head is very extensive, and confined only towards the back, in which direction it is opposed by the projection of the back. The muscles which move the head are situated within the thorax: the membranes or ligaments extend from the anterior part of the collar to the surface of the occipital foramen.

*Brain, or Medullary Substance.*—According to the “*Fundamenta Entomologiæ*,” it was the idea of Linnæus, that insects have no brain in the head; an opinion often repeated since his time, but which, from the observations of the ablest physiologists of the present period, proves to be unfounded. Linnæus does not deny the existence of a medullary thread in this part of insects, but states that he never could discover it to be organized; and hence, he says, the hippobosca equina, or horse-fly, will run, live, nay even form an union with the opposite sex, after being deprived of its head, to say nothing of many others, which are capable of living for a considerable while in a decapitated condition. From the anatomical investigations of Cuvier it is, nevertheless, sufficiently obvious, that independently of a nervous medullary thread, insects have a brain distinctly organized, from which this thread and other nerves arise, and that its seat is in the head, as in the more noble tribe of animals. The existence of a true brain in insects was believed by many writers before the time of Linnæus, and by some after; but, generally speaking, the opinion of this celebrated naturalist was assented to, and enquiry ceased, till its consideration

was revived by Fabricius, and the physiologists of France, the most distinguished of whom is Cuvier, and from the result of their observations it may be affirmed, that insects, as well as most other animals, have a genuine brain.

Fabricius is reputed to be the first who discovered the true brain in insects. That Fabricius asserts the fact, and that as an entomologist his assertion was successfully opposed to the opinion of Linnæus in this respect, is not to be denied, yet the merit of discovery is by no means due to this writer. His observations on the brain, the organs of hearing, and other sensations of insects, were made chiefly on the lobster or cray-fish, animals of the crustaceous kind, and which, though in some respects analogous, we do not admit to be of the insect race. But if they were, can we have so entirely forgotten the anatomical investigations of cancer attack by Roesel, as to allow Fabricius the credit of discovering those very organs which he describes many years before; and if he really observed those organs in genuine insects, can we overlook the laborious anatomical enquiries of Swammerdam, or the minute researches of Lyonnet, in which the existence of such an organ is rendered manifest, with no other view than to award the merit of its discovery to Fabricius?

No physiologist whatever has pursued this interesting subject of enquiry so far as Cuvier. This attentive and skilful observer examined a considerable number of the different tribes of insects, in order to ascertain their internal organization, and has established, beyond dispute, if any doubt could still remain, that insects have a brain in the head. From Cuvier we also learn that the brain is not constantly of the same structure in all insects; in some tribes this organ consists of one lobe, in others of two, and in others again of four; and the nerves arising from them differ also very materially in different families, and sometimes even in species. But besides this dissimilarity, there is another circumstance infinitely more remarkable, the form of the brain and medullary nerves in certain insects, are ascertained to undergo a considerable change, as well as the external organs, in passing from the larvæ to the perfect state. The most extraordinary of these deserve notice, and the circumstance being stated may stimulate others, perhaps, to a farther enquiry, in the result of which, it is apprehended, a similar change, will be observed, in a far greater number of the insect race than may be at present conceived.

*Brain in Coleopterous Insects.*—The larva of a large beetle, common in Europe, and known by naturalists under the name of scarabæus nasicornis, affords a favourable opportunity for the ascertainment of this fact; it is of a large size, and the change it undergoes in passing to the winged state is very considerable. The brain in this larva is situated under the great scale which covers the head, immediately above the origin of the œsophagus. It consists of two approximate lobes, which are very distinct at the front and back part. Four nerves arise from the anterior part, two on each side, which are lost in the cirri and parietes of the mouth, one pair of nerves arises also from the lateral and somewhat posterior part of the brain, which, embracing the œsophagus, proceeds below to form a nervous cord; and another pair is produced from the lower surface of the brain. In the perfect insect, the nervous cord presents a very conspicuous difference; in the larva there is only a single ganglion, but the perfect insect has several, and which are very distinct. The first is situated above the condyle; it proceeds from the two posterior filaments of the brain, and is distributed to the muscles which move the head on the corselet. Its posterior part produces two filaments, which pass into the breast, where they unite towards the middle,

middle, and form a triangular ganglion, from the sides of which three pairs of nerves arise, and are distributed to the muscles. Its posterior angle detaches two parallel nerves which proceed into the breast, where they form a third and fourth ganglion, situated very near each other, and apparently divided into two lobes by a longitudinal furrow. All the other nerves of the body proceed from these two ganglia, by an irradiation precisely in the same manner as in the larva.

The nerves in the larva of the stag beetle (*Lucanus cervus*) differ greatly from that of the foregoing insect. The brain consists of two contiguous and almost spherical lobes, which produce four nerves anteriorly; two beneath and two behind, which latter form a collar round the œsophagus, and uniting underneath compose the nervous cord of the body. The cord is formed of eight ganglia, and extends to the ninth ring of the body. In the perfect state the brain consists likewise of two approximate lobes of a spherical form. There are also two ganglia on the lateral parts of the brain, which are almost as large as each of the lobes: in form they resemble a pear, and rest on the brain by their base: the two anterior pairs of nerves arising from the brain terminate in the palpi and other parts of the mouth. The brain produces also two very long and slender nerves behind, and the disposition of the nerves arising from the various parts differ very much from those observable in the larva.

The nervous system of the larva of *Hydrophilus piceus*, or great water beetle (*Dytiscus*, Linn.), will serve to illustrate those of an extensive number of other coleopterous insects, such as the larva of *Cerambyces*, *Dytisci*, *Carabi*, *Staphylini*, &c. Some little variation will be found, but the analogy is very conspicuous. The brain in the larva of this insect is situated in the head above the origin of the œsophagus; it is formed of two lobes, which lie very close together. From its anterior part it detaches some filaments to the palpi, the antennæ, and the parietes of the mouth. Its lateral parts produce two cords, which surround the œsophagus, and which are the origin of the nervous cord situated inferiorly. The chief nervous cord is composed of ten ganglia, each of which produces three pairs of nerves, which are lost in the muscles of the abdomen. In the perfect insect the brain consists of two spherical bulbs, which are closely united. The lateral parts give origin to the optic nerves. The anterior part of the brain detaches some filaments intended for the parietes of the mouth. In the same place is also a small spherical ganglion, which seems to belong to the recurrent nerve that accompanies the œsophagus. The brain in the larva of *Dytiscus marginalis* is different from that in the larva of *Hydrophilus piceus*, although those two insects are so closely allied in genera; in the latter it is spherical, and consists of a single lobe, it is situated in the head above the origin of the œsophagus: its anterior part produces some filaments for the mouth, and its lateral parts the two optic nerves: the latter are composed of two parts, which are very distinct in form. That portion next to the brain is of an oval figure, pointed at the extremity which joins the brain, the other extremity is rounded, and produces a slender nerve, which passes directly to the eye.

*Hemiptera*.—The structure of the nervous system in the larvæ of hemipterous insects does not often differ very sensibly, it is said, from that which is exhibited in the perfect insect to which they respectively belong. But the small number of this tribe already examined do not authorize us to speak on this subject with much confidence. A considerable difference prevails in this respect between the perfect insects of some opposite genera, as appears from those which Cuvier

describes. In the cock-roach, *Blatta americana*, the brain is composed of two lobes, separated by a very distinct notch anteriorly. The optic nerves arise on the sides, and its anterior part detaches some filaments to the parietes of the mouth, and to the instruments of manducation. The nervous cords, which form the medulla, arise from its inferior surface. In the great green locust (*Gryllus viridissimus*) the brain is situated in the head above the œsophagus; it consists of two lobes, which are pyriform, united at their base, and prolonged at their other extremity into an optic nerve for the eye of each side. The anterior part also produces two nerves of a pyramidal form, the base of which rests upon the brain. The brain of the mole-cricket (*Acheta gryllo-talpa*) is composed of two rounded lobes, which are particularly distinct at the posterior part. The nervous system of the water scorpion (*Nepa cinerea*) is different. This consists of three ganglia, the first of which (properly the brain) is situated in the head. It is formed of two approximate pyriform lobes, which touch each other at the base, while their summits are directed obliquely forward towards the eyes in which they terminate: the middle and anterior part of these lobes also produce filaments for the parts of the mouth; the third, which is more voluminous than the brain, lies near the base of the second pair of legs.

*Lepidoptera*.—The nervous system of caterpillars, or lepidopterous insects in the state of larvæ, consists of a series of thirteen principal ganglia, which furnish filaments to all the other parts of the body. The first of these ganglia is what may properly be considered as the brain: it is situated in the cavity of the head above the œsophagus, and consists of two round tubercles, which are concave beneath, and correspond to the convexity of the œsophagus. This ganglion communicates with the rest of the nervous cord by two thick filaments, which embrace the œsophagus, and which are united below it to the anterior and lateral parts of the next ganglion; and it besides produces eight pairs of nerves. The first partly unites with other filaments; produces some for the œsophagus, and forms several remarkable ganglia below the lower lip. The largest and most posterior, which Lyonet has named the first frontal ganglion, is prolonged behind into a thick recurrent nerve, which is continued the whole length of the body contiguous to the back. The second pair of the brain appears chiefly intended for the antennæ, though it furnishes several filaments to the neighbouring parts, and the others for the more remote portions of the body. These observations are from Lyonet, and relate principally to the larva of the goat moth (*Phalæna cosus* of Linnæus.) Few of the lepidopterous insects in the winged state have yet been examined for the purpose of ascertaining the structure of the brain. In *Phalæna dispar* this organ is almost spherical; there is, however, a longitudinal furrow on the middle line. Its anterior part produces some exceeding slender nerves. There are also two large optic nerves on the sides which proceed into the concavity of the eye, where they terminate by a bulb, from whence arise a great number of filaments.

*Neuroptera*.—In the larva of the lion-ant, (*Myrmellon formicarius*) the nervous medulla, proceeding from the brain in the head, consists first of two ganglia, which are composed of two lobes situated close together, and are placed in the thorax; the remainder of the nervous medulla, consisting of eight ganglia placed in very close series, and each formed of two lobes, is contained in the abdomen. The larva of the ephemera has eleven ganglia, exclusive of the brain, which furnishes two large optic nerves. The larvæ of the libellulæ, or dragon flies, have a small two-lobed brain, which produces optic nerves, larger or smaller in different species.

The Fabrician genus *æstha* has the largest. The rest of the nervous system forms a series of ganglia of different sizes. In the *æstha* the thorax contains six, the two last of which are the largest, and there are seven small and equal ganglia in the abdomen. In the winged state the brain is formed of two very small lobes, and the optic nerves are dilated into the form of two very large plates, which have the figure of a kidney, and which is spread upon all the inner surface of the eye next the head. The remainder of their medullary cord is exceedingly slender, and furnished with twelve or thirteen small ganglia, the last of which is, as usual, connected with the organs of generation.

*Hymenoptera*.—The brain in the larvæ of some kinds of tenthrédines, which have the head large, is broad and short, and seems to consist of four bulbs of equal magnitude, and the form of which is nearly spherical; the two external ones serve as the base of the optic nerves, which are slender, and enlarge a little at their other extremity. The first ganglion is produced by two very small nerves, which arise from the inferior surface of the brain, and which, after having embraced the œsophagus, unite under the first ring of the body; it furnishes filaments to the muscles of the feet, and terminates posteriorly in two other nerves, which, at the distance of one line, produce a second ganglion, and so on in succession: the nervous cord is in this manner formed of eleven ganglia, exclusive of the brain: all the ganglia are of a roundish form, and diminish in thickness as they recede from the head. The brain of one of the hymenopterous tribe in the winged state (the common bee) is rather small, and is divided into four lobes. It produces the nerves which are distributed to the different parts of the mouth, and the two large optic nerves which are dilated, and applied behind each eye, as in the libellulæ. There are afterwards seven ganglia, three of which are in the thorax and four in the abdomen. The nerves of the last chiefly supply the sexual organs.

*Diptera*.—The nerves of the larvæ, in some of the Linnean muscæ, as *m. chamæleon*, &c. (*stratiomys*, Fabr.) have some resemblance to those of the larvæ of *scarabæus nasicornis*. The brain is formed of two lobes placed close together and almost spherical; it is situated above the œsophagus, on a level with the second ring of the body. A number of small nervous filaments arises from its anterior part, and they are distributed to various parts of the mouth. The posterior part of these two lobes sends forth two thick branches, which embrace the œsophagus, and form the origin of the nervous medulla. This nervous cord is very short, and in diameter one half less than that of the brain. It consists of eleven ganglia placed very near each other, each of which produces one pair of nerves.

A more singular appearance is exhibited in the structure of the nervous system of *musca putris* than that just described. The brain is situated immediately above the origin of the œsophagus behind the head; it is very large in proportion to the rest of the body. The anterior part is notched, posterior rounded, and appears altogether as if formed of two lobes. A pair of nerves arises from the anterior part of the brain, proceeds forward, and is distributed to the mouth. These nerves become conspicuously large previously to distribution. Posteriorly the brain presents an aperture which affords a passage for the œsophagus: the nervous part, situated at the sides, may be regarded as cords which produce the medulla, and all below the œsophagus as the medulla itself.

*Musca tenax* (Linn.) in the perfect state has a small brain, formed of two lobes, which are situated very near together, but distinguished by a longitudinal furrow; the anterior part produces a large nerve, which is afterwards distributed to

the antennæ and the proboscis. In *æstus crabroniformis* is a single cord uniting the abdominal ganglia, which are six in number. The brain itself is similar to that of the syrphus (as in *musca inanis*, &c.) but the bulbs formed by the optic nerves are still broader in proportion to the extent of the eyes they have to invest.

*Aptera*.—In the great centipede, *scelopendra moritans*, the brain has a very singular form: the two lobes of which it is composed are almost spherical; the optic nerve is produced laterally and is very short. The filaments are four in number, but two nerves arise anteriorly which are so very thick, that they appear part of the brain, to which they are equal in diameter. These nerves are particularly intended for the antennæ, into which we observe them enter. The two cords which embrace the œsophagus proceed directly downward, and form a large ganglion at the union of the first ring with the head. The first ganglion produces two nerves posteriorly, and several towards the sides. A ganglion, precisely of the same shape, is placed above each of the articulations: thus there are in all twenty-four very distinct ganglia in this insect, from each of which are detached three pairs of nerves.

*Mouth*.—In order to afford some idea of the amazing difference that prevails in the structure of the several parts or organs which constitute the mouth, it will be only requisite to observe that the classification of all insects, in the Fabrician system, is founded on this character. There are ten principal parts of which the mouth consists; and it is from the relative proportion of each, from the dissimilarity in the form, position, variation in number, or occasional peculiarities, that the most permanent characters are deduced. These parts have one disadvantage: they are generally small, and from this circumstance have not been so universally adopted in the arrangement of insects as they would otherwise. Without, however, bestowing some little attention to these organs, it is impossible to distribute insects into their natural order with any great degree of certainty.

The organs of the mouth were slightly regarded by Linneus; and to this cause alone we may attribute some few serious errors in the works of that naturalist. The parts he describes are the rostrum (or proboscis); maxilla, lingua, and labium superius. Some of these are not sufficiently discriminated; his rostrum and proboscis are not different; the maxillæ are confounded with the mandibulæ; and the labium superius is not, as the expression implies, the upper lip of the insect, this latter part being situated under it. Fabricius defines these parts with more precision, as he derives his essential characters from them. In the arrangement of Olivier, in the works of Latreille, and most other modern writers on entomology, the essential characters are established chiefly on the peculiarities of these organs.

The ten principal parts of which the mouth consists are the following.

*Labium superius*, or upper lip: a transverse, soft, moveable piece of a coriaceous or membranaceous nature, known from its situation at the anterior or upper part of the mouth. This part is very distinct in many of the coleoptera, and in the gryllus, apis, and some other genera. Linneus sometimes confounds the upper lip with the clypeus or shield of the head; and similar instances occur in the works of Fabricius. These two parts may be distinguished by one invariable character; the clypeus is fixed, and forms a portion of the head; the upper lip is moveable.

*Labium inferius*: the piece which terminates the mouth beneath, and which is sometimes lengthened, so as to form the instrument called ligula. It is soft, flexible, usually

bifid, and has the posterior pair of feelers placed at the base.

*Mandibulae*, mandibles: two hard pieces, in substance resembling horn, which are placed one at each side of the mouth, below the upper lip. These have a lateral motion, while the upper and lower lip move up and down, as in other animals. These differ from the maxillæ, with which they are sometimes confounded, by not having any of the palpi or feelers attached to them. In rapacious insects, these are larger and more powerful than in those which perforate wood; and the latter again have stronger mandibles than insects which feed only on herbage or leaves.

*Maxillæ*: two small pieces of a somewhat membranaceous consistency, and in figure different from the mandibles. These are commonly indented at the extremity, and nearly all ciliated at the inner edge. They are placed under the mandibles, and above the lower lip; their motion is lateral. In those insects which have more than one pair of feelers, the posterior ones take their origin from the sides of the maxillæ.

*Galeæ*.—Shields of the mouth, two membranaceous appendages, usually of a large size and cylindrical form, placed one on each side, at the exterior part of the jaw, and which cover and protect the organs of the mouth, conjointly with the lips. The galeæ are inserted at the back of the jaws, as is well exemplified in the gryllus tribe.

*Organs of Taste.*

These appertaining of course, like the foregoing, to the mouth, and of which they constitute the most material part, admit of considerable variety in their formation, and in some particular tribes differ so greatly as to have obtained distinct names in the works of entomologists, according to their precise form; such, for example, as ligula, lingua, rostrum, proboscis, and haustellum.

*Ligula*.—This is the part considered by many authors as the lower lip; its situation is immediately under the jaws; and it consists of a single piece, which is of a soft texture, often bifid, and, if attentively examined at the base, will be found of a horny substance.

In the coleoptera, and some of the hemiptera, as the blatta, phasma, gryllus, &c. this tongue terminates at the point in a membranaceous substance: its form is extremely various in the different genera. The hymenoptera and some neuroptera have the tongue or ligula situated in the same manner; but it is in these concave, and is frequently prolonged into a sort of proboscis, which sometimes exceeds the length of the whole body. It is membranaceous, but of a soft and spongy texture, and well suited for receiving the impressions of taste. This kind of tongue is extremely well exemplified in the bee.

*Lingua*: tongue, the involuted tubular organ which constitutes the whole mouth in lepidopterous insects. This is of a setaceous form, and either very long, as in the papilio and sphinx genera, or short, as in most of the bombyces and other moths. It consists of two filamentous pieces, which are externally convex, concave within, and connected longitudinally by a suture along the middle above and beneath. These in uniting form a cylinder, through which the nectareous juices of the flowers on which these insects subsist are drawn up with facility. These two pieces are not very closely united, and may be separated by means of a needle point. When the insect takes its food, this tube is exerted; at other times it is rolled up spirally between the palpi.

A curious circumstance is mentioned by Degeer, relative to the tongue of the butterfly. Having cut off the

tongue of a papilio antiopa, almost as soon as it was emancipated from the chrysalis, it moved and rolled itself up at intervals for a considerable time: an hour after it had been cut off it repeated the same motions, recommencing them every time it was touched. It was observed that the same effect did not follow, if the butterfly had been liberated from the chrysalis for a few days.

*Rostrum*, or beak: the part which forms the mouth in many of the hemipterous order of insects. This instrument is moveable, articulated, and bent under the breast. Within this beak is hollow, and contains, as in a sheath, three or more very fine and delicate bristles, the points of which these insects introduce into the body of the animal, or substance of the plants, from which they draw nourishment. The rostrum is conspicuous in the genera cicada, nepa, and cimex.

*Proboscis*.—The trunk is inserted in place of the mouth, in most dipterous insects. It is rather fleshy, retractile, of a single piece, and often cylindrical; the end forming two lips, which are of a soft substance, and from the delicacy of their teguments must possess the faculty of taste in a very high degree.

*Hauſtellum*.—Formed of two or more very small and delicate filaments, inclosed in a sheath of two valves.

Lingua, rostrum, and proboscis, are Linnæan terms: the first is adopted according to the definition of that system; the two latter are synonymous with Linnæus. Ligula is a Fabrician expression, indicating the lower lip.

*Palpi*.—Feelers. These are the small, moveable, filiform organs, or appendages, placed at each side the mouth in the generality of insects. In some respects they resemble the antennæ, but are more distinctly articulated. They vary in number in different insects, being either two, four, or six, and are commonly inserted at each side the exterior part of the jaw. In those which have only one pair, they are usually situated on the upper lip; when two or more, the posterior ones are generally on the lower lip; and in some insects furnished with a sucking trunk, they are oftentimes found inserted at each side of that organ. These feelers are composed of several joints, the number of which vary. Like the antennæ, to which they bear analogy, they are endowed with powers of motion, but still more extensively. They also serve, like the antennæ, as an essential character in the construction of genera; and from their situation, the number of joints, termination, and relative proportion and size, are exceedingly useful for that purpose.

These feelers, as their name implies, are considered as the organs of touch; and this is conceived probable, because the insect agitates these parts, and presses its food with them before it begins to eat. Some have supposed them to be the organs of hearing; and others of a sense peculiar to insects, which we are ignorant of. It has been ascertained from experiment, that they are not absolutely necessary to the life of the insect, and that it even sustains their loss without much apparent inconvenience. Feelers are not common to all insects. There are many whole genera destitute of them; as, for example, the fulgora, cicada, the several genera of the Linnæan cimices, nepa, notonecta, and various others.

Certain kinds of insects are provided with feelers, both in the larva and perfect state, as is particularly exemplified in the dytiscus and hydrophilus genera, and again in the libellule; and it is worthy of remark, that these organs appear to be more immediately useful to the carnivorous tribes of insects than to those which feed on plants.

*Olfactory organs*.—Nature has denied the insect race that particular part which is properly called the nose; and it is

## ENTOMOLOGY.

further evident, that there is no organ within the head appropriated to the sense of smell. From analogy, and comparison with other animals, naturalists have been led to seek this organ in the head: and as insects afford the most convincing evidence of being possessed of this faculty, some have placed it in the antennæ, and others in the feelers; neither of which, from attentive examination, appears calculated for this purpose.

It is sufficiently clear that insects possess the faculty of smell, if not in a very eminent degree, and that in many respects they are rather guided by this sense than by the force of instinct. Insects discover their food at a great distance, and, as it is supposed, by this means; and it is concluded likewise, that butterflies and moths are directed by the same sense to the discovery of their mates. A female of *phæna quercus* (egg-moth), inclosed in a box, and thus exposed in an avenue of a wood, will attract the males in numbers to the same spot; and though she cannot possibly be seen, they will appear fully sensible of her presence. Admitting that these circumstances may be otherwise accounted for, one argument at least bears strongly in its favour, namely, that of the flesh fly (*musca vomitoria*) being so far deceived by the similarity of odour, as to lay its eggs on plants of the *stapelia* genus instead of animal substances. These insects, as the name implies, subsist in the larva state on flesh, preferring that which is putrid, or hastening to the stage of putrefaction, and from whence, in consequence, a powerful odour arises. The plants of the *stapelia* genus have the same smell; and the parent insect, misled by this means, actually deposits her eggs on these plants.

As instinct never errs, though judgment may, it is a natural inference that the insect is not in this instance under the controul of instinct, but of her own will, because otherwise she would not fail to lay those eggs in flesh, where the larva, when hatched, would be provided with food; while, on the contrary, the plants resemble this food only in its offensive odour, and thus, when hatched, the infant brood inevitably perish. Does not this afford presumptive evidence at least, that the insect is directed to these plants by the organs of smell?

If insects then evince such apparent proofs that they do possess this faculty, and that it appears likewise the seat of this faculty does not reside in the head, it must be sought after in some other part. The organs of smell, in all animals which respire air, is situated at the entrance of the organs of respiration: from this circumstance it is conceived most likely that the respiratory spiracles on each side the body must be the true organs of that sense. This idea was advanced by Baister; yet it seemed to imply such an inversion in the ordinary course of nature, that it gained little credit. Of late years the same opinion has obtained the concurrence of the best anatomists. Cuvier is decidedly in favour of this conclusion, and, in addition to the reasons hitherto stated in its support, observes, that the internal membrane of the tracheæ appears well calculated to perform this office, being soft and moistened; and that the insects in which the tracheæ enlarge, and form numerous or considerable vesicles, are those which seem to possess the most perfect sense of smell. Olivier endeavours to maintain that the palpi or feelers, and also the antennæ, are the olfactory organs in insects.

*Eyes.*—Most insects have two eyes. These are placed in the anterior part of the head, and vary very much in their external figure in different tribes. Some of the Linnæan insects of the apterous-order have a greater number, the scorpions have eight, and the spiders from six to eight, and

there are besides other genera in which the eyes amount to more than two.

This pair of eyes in the insect race is of a compound kind, while those of the scorpion and spider are simple, and in this respect the difference is very remarkable. The compound eye is one of the most extraordinary deviations from the ordinary course of nature in the conformation of the organ of sight; the simple eyes approach much nearer those of other animals. By compound eyes we mean those kinds which are reticulated, and when magnified are found divided into a great number of compartments, and of these every genuine insect appears to possess two. Besides these eyes, many of the neuropterous and hymenopterous families have three small shining convex points placed in the middle of the head, and called by entomologists *stemmata*, the utility of which has never been ascertained. The extreme minuteness of these organs does not allow the comparative anatomist the means of dissecting them, but we still think they can be no other, than organs of sight. Should this appear doubtful, because we observe them in those insects, which are besides furnished with a pair of eyes of the compound kind, it should be recollected that scorpions and spiders, as before-mentioned, have several more eyes than a pair; and if, on the other hand, the simplicity of their structure be considered as an argument against this conclusion, let it be observed that they possess every character in their form, appearance, situation, and immovability, which the only kind of eyes these creatures are furnished with are known to possess. We, indeed, conceive it very probable, that those three shining points, called *stemmata*, are truly organs of sight; and that, consequently, many insects which appear to have only two eyes, have in reality no less than five.

The compound eye in insects is so very different from that of other animals, that it would be difficult to persuade ourselves of its being an organ of sight, had not experiments, purposely made, demonstrated its use. If we cut out, or cover with an opaque matter the eyes of a libellula, or dragon fly, it will strike against walls in flight. The wasp is said to ascend perpendicularly in the air till it completely disappears, when the compound eyes are treated in the same manner, and to remain perfectly immovable when both the compound eyes and the *stemmata* are covered; in the first case it seems to follow the direction of its flight upwards, in the other to be deprived entirely of the visual organ, and uncertain whither to direct its flight.

The compound eyes are generally convex, and when viewed by the microscope exhibit an innumerable multitude of hexagonal facets, slightly convex, and separated from one another by small furrows, which frequently contain fine hairs, more or less long. These facets give, to the naked eye, the appearance of net-work, and amount to a greater or less number in different insects. Leeuwenhoek counted 3181 in the eye of a beetle, and in that of the common house fly about 8000.

These facets form altogether a hard elastic membrane, which, when freed from the substances that adhere behind, is very transparent. Each of these small surfaces may be considered either as a cornea, or a crystalline, for it is externally convex, and concave internally, but thicker in the middle than at the edges, and it is also the only transparent part in this singular eye. Behind this transparent membrane is a substance, which varies greatly as to colour in different species, and which sometimes forms, even in the same eye, spots or bands of different colours. Its consilience is the same as that of the pigment of the choroides; it entirely covers the posterior part of the transparent facets, without leaving any aperture

aperture for the passage of the light. Behind this pigment we find some very short white filaments, in the form of hexagonal prisms, situated close to each other, like the stones of a pavement, and precisely equal in number to the facets of the cornea; each penetrates into the hollow part of one of these facets, and is only separated from it by the pigment mentioned above. If these filaments are nervous, we may consider each as the retina of the surface behind which it is placed; but it will always, in the opinion of Cuvier, remain to be explained how the light can act on this retina through a coat of opaque pigment. This multitude of filaments, perpendicular to the cornea, have behind them a membrane, which serves them all as the base, and which is consequently nearly parallel to the cornea: this membrane is very fine, and of a blackish colour, which is not caused by a pigment, but extends to its most intimate texture; we observe in it very fine whitish lines, which are trachææ, and which produce still finer branches that penetrate between the hexagonal filaments as far as the cornea: this membrane by analogy Cuvier calls the choroides. A thin expansion of the optic nerve is applied to the posterior part of the choroides. This is the real nervous membrane, perfectly similar to the retina in red-blooded animals; it appears that the white filaments, which form the particular retinæ of the different ocular surfaces, are productions of this general retina, which perforates the membrane named choroides by a multitude of small and almost imperceptible holes. To obtain a distinct view of all these parts, it is necessary to cut off the head of an insect which has the eyes of large size, and dissect it behind, each part will then be removed in an order, the reverse of that above described.

The construction of these compound eyes is admirably adapted to the convenience of the insect, for as the eyes of insects are immoveable, they would have lost sight of many objects, if their eyes had been framed like those of other animals, but by these means they can easily view surrounding objects. It seems a false conclusion that as each of the facets which compose the compound eye is a distinct organ of sight, any single object must appear multiplied as often as there are facets; it is, on the contrary, far from improbable, that as objects do not appear double to our eyes, but that the visual organ is strengthened, and many illusive appearances are corrected by the use of both, so the numerous inlets to sight in an insect may increase their field of view, and be productive of other advantages, of which we are ignorant.

*Stemmata*: the three smooth, glossy, hemispherical dots, situated at the vertex of the head, and which, as just observed in speaking of the eyes, are supposed to be organs of sight. These are most conspicuous in the hymenopterous order of insects.

An experiment made by abbé Catalan tends to confirm the truth of this conjecture. With the view of observing whether an insect could see equally well with both the eyes and stemmata, he covered the reticular eye of a fly with fluid pitch, leaving the stemmata open; he then put it under a glass, where it ran up and down without striking against any object, and when he lifted the glass, it flew away towards the window. He took another fly, and covered with pitch the stemmata, leaving the reticular eyes open, and found that with these it saw equally well as before. Lastly, he took a third fly, and covered both the reticular eyes and the stemmata, and this he found completely blind; it walked slowly under the glass, and when removed would not venture to fly. *A. & Erudit. A. D. 1682.*

*Antennæ* are those delicate moveable horns which ap-

pear on the fore part of the head in all perfect and genuine insects; and which, in many instances, are very remarkable for their beauty and elegance of structure. The antennæ are extremely diversified in form, and vary considerably in their proportional dimensions in different tribes; and for this reason are considered by entomologists of material consequence in distinguishing the various orders, genera, and species. These parts are always articulated, or consist at least of more than one joint, including the base, and most commonly are composed of a far greater number; few less than eight, ten, or twelve, and some amounting to twenty, or even more. This articulated structure of the antennæ is of infinite utility to the insect, as it is thereby enabled to move these organs in every direction their wants or wishes may require.

Antennæ are not entirely peculiar to insects; the crustaceous animals possess the same organs, though in other respects they differ so essentially, (see article *CANCER*;) as do likewise some of the apterous order of Linnæan insects, which modern naturalists exclude from this class. Nor will it be amiss to observe that, even according to Linnæus, many of his apterous insects are destitute of antennæ, and are consequently inadmissible on this account, upon his own definition, into the system of entomology. Spiders and scorpions are of the latter description. The organs termed antennæ are easily distinguished from the tentaculæ of vermes, by having a shelly covering, and from the palpi or feelers of insects, the latter being more numerous, and situated at the mouth. The Linnæan and Fabrician entomologists admitting the cancer, and other crustacea among the insect tribes, allow four, or in some cases even six antennæ to this race, but as we refer these to another class, we apprehend that the number of antennæ in all genuine insects invariably amounts only to two. Those insects which have attained their last state, and are therefore denominated perfect, and which possess six legs, are always provided with two antennæ. It is true that the larvæ of many insects are not furnished with these organs, yet they are still genuine insects, because in their complete state they possess them; spiders and scorpions on the contrary, with all their organs complete, have no antennæ. A very considerable number of insects, even in the larva state, are not deficient in these organs, and in many, though not in all, there is no difference whatever between the antennæ of the larva and perfect insect. The genera blatta, gryllus, mantis, phasma, cimex, and various others of the hemiptera order, are furnished with antennæ, which exactly resemble those of the same species in their perfect state.

No writer, who has attentively regarded the structure of the antennæ in insects, has hitherto pretended to determine precisely the purpose for which nature has designed them, and those who have not very maturely considered them cannot possibly be competent to decide such a doubtful circumstance. We know of nothing analogous to these organs in larger animals whose manners we might be supposed to have a better acquaintance with, and it is not therefore by analogy that this point can be determined. Some naturalists conceive that they are appropriated to a feeling more delicate than our own, and that they are sensible to the least motion or disturbance in the ambient fluid, or that they are the organs of some sense unknown to us, and of which we cannot consequently form the least conception. Some suppose they serve to sound, and occasionally to probe the earth on which they move, or that they are the organs of hearing, of feeling, or smelling, and by the means of which they distinguish their proper food. Each of these conjectures

is liable to objection, and can be considered as an opinion merely, while the real purposes of these organs may perhaps for ever remain unknown.

Though it is difficult even to conceive the immediate object for which the Creator has assigned these organs to the insect race, we must rest persuaded that they are intended to answer some very important destination in the economy of the animal, as the medullary nerves, arising directly from the brain, may be traced into these parts, and followed throughout their whole extent. In some insects also, which have the antennæ small, the palpi are observed to be very large, as if they were intended to answer the same purpose, or partake of the same sense, as the antennæ; and thus, by their mutual aid, supply the deficiency of antennæ. This will in some degree account, perhaps, for the manner in which nature seems occasionally to counterbalance the want of antennæ in the larvæ of certain kinds of insects which have palpi, but no antennæ; others in the same state have antennæ and no palpi. Many that are destitute of both the two first-mentioned kinds are those chiefly which prey on insects, and the latter such as feed on plants.

The antennæ, nevertheless, appear to us to be rather connected with the organ of hearing, than either that of feeling or smelling. The palpi, we have little doubt, are the organs of feeling, both from their texture, and the manner in which insects are oftentimes observed to make use of them in touching their aliments; and the organs of smelling in insects, however singular it may be imagined, we conceive to be no other than the apertures disposed on each side the thorax and body. By the organs of hearing, we do not mean to consider them as external ears, but as being in some manner auxiliary to the organ of hearing, the seat of which we suspect to be contiguous to the base of the antennæ, the spot in which the same organ has been discovered in the cray-fish. They may answer this and some other purpose likewise.

We have previously observed, that nothing can be distinctly inferred of the actual utility of the antennæ from analogy; nor do the purposes to which insects appear sometimes to appropriate them assist our conclusions in a satisfactory manner. Many insects, when they walk, fly, or take their food, have the antennæ directed forward; others, on the contrary, carry them inclining backward, like the cerambyces; some kinds lay them along their back; and others, as the elater tribe, dispose them on each side the thorax. The sphæges and the ichneumons bear their antennæ directly before them, and continually agitate them, whether in flight, when standing, or seizing on their prey. In others, the antennæ have little perceptible motion. Some insects are said to cover their eyes with their antennæ when they sleep; the diminutive size, compared with the magnitude of the eyes in most insects, will not permit us to believe that this is the principal object of their destination.

Notwithstanding the direct connection of the antennæ with the brain, insects, it has been affirmed, can undergo their partial privation, or total loss, without experiencing any sensible injury; and hence it has been concluded they cannot be necessary to the life of the insect. If the fact be true, the latter inference must surely be admitted, but this will not disprove their utility: nor will it discountenance the idea that the antennæ are requisite for some important end. We well know, that in the animal economy of larger beings, not only the medullary nerves may be in part destroyed, but even the animal be deprived of a portion of the brain itself, without sustaining mortal injury. The antennæ of insects may not be absolutely necessary to the life of the in-

sect, but are certainly so to its well being, and to the perfect exercise of all its functions.

The antennæ of the male insects generally differ from those of the females. It is principally the antennæ of the former that are plumose, or furnished with teeth, or tufts of feathers, while those of the female appear like a delicate thread, entirely smooth, or only slightly pectinated. This is observable throughout the moth tribe. In coleopterous insects the males are often distinguished by the superior size and beauty of the antennæ from the other sex. The antennæ are characterized by entomologists according to their structure under different names. Linnæus describes the following: 1, *Setaceæ*, those which gradually become taper towards the extremity; 2, *Filiformes*, such as are of an equal thickness throughout; 3, *Moniliformes*, are filiform like the preceding, but consist of a series of round knobs, like a neck-lace of beads; 4, *Clavatæ*, such as gradually increase in thickness from the base, and form a club at the end; 5, *Capitatæ*, like clavatæ, increase in thickness towards their extremity, but are distinguished from those by the form of their last articulation, which is larger and more rounded than the others; 6, *Fissiles* are like the last, but are divided longitudinally into three or four plates or laminæ; 7, *Perfoliatæ* are also capitatæ, but have the head divided horizontally, the plates being connected by a kind of thread passing through their centre; 8, *Pectinatæ* are those which have lateral appendages, like the teeth of a comb, or plume of a feather, as in the moth tribe. 9, *Aristatæ*, such as have a lateral hair, which is either naked, or furnished with lesser hairs, as in the musca genus. Each of these is also distinguished according to their length, as *breviores*, those which are shorter than the body; *longiores*, those which are longer than the body; and *mediocres*, such as are of the same length with the body, all which varieties are conspicuous in the Linnæan tribe of cerambycæ.

The structure of the antennæ in insects is of such vast importance in the definition of genera, species, and sexual distinctions, that it is to be regretted we have not a more comprehensive number of terms by which their particular forms might be minutely discriminated. Linnæus affords us some, the utility of which is universally allowed; others which he proposes require some revival and modification; and among the innumerable number of insects discovered since the time of Linnæus, the antennæ of many exhibit characters which cannot be expressed by any of those his work presents. Fabricius has others, but these, even in addition to those of Linnæus, are not adequate to the purpose.

#### *Organs of hearing at the base of the Antennæ.*

The organs destined by nature for the conveyance of sounds to the seat of the senses in the insect race have never been clearly ascertained. This can be attributed only, perhaps, to their minuteness, which defies investigation, except in some few of the larger kinds, and these even physiologists seem never to have examined. In the cray-fish the organs of hearing are exemplified by Fabricius and Scarpa. These were discovered within the head, at the base of the antennæ, through the hollow tube of which it is supposed the sound must be conveyed. Perhaps, from the analogy in certain respects, which this tribe of crustaceous animals bears to insects, it may be imagined that the organs of hearing in both are similar: this is very probable; but these two orders of creatures differ so essentially in several particulars, that we wish to express such an opinion with caution.

In the cray-fish the labyrinth of these organs is very simple, resembling a small purse, enclosed in a scaly cylinder open at both ends. The extremity by which this small cylinder joins the base of the antennæ affords a passage for the nerves into the purse. The opposite extremity is closed by an elastic membrane, which may be named tympanum, or, with more propriety, Cuvier thinks, fenestra ovalis. The air, or water in which the animal lives, acts immediately on this membrane, the external part of which is observable at the lower surface of the base of the antennæ. That insects are sensible of sounds, and, consequently, are furnished with organs of hearing, is demonstrated by numberless observations.

*Front*: the anterior or fore part of the head, the space between the eyes and the mouth.

*Clypeus*: shield of the head in coleopterous insects, the part corresponding with the front of the head in the other orders. In the beetle kind it is advanced more or less upon, or over the mouth, and in some forms a sort of cap, the rim of which extends so far over the head as to conceal the mouth beneath. The anterior edge of the clypeus is sometimes mistaken for the upper lip.

*Vertex*: the crown, or summit of the head.

*Gula*: that part which is opposed to the front of the head, usually called the throat.

*Trunk*: the second principal division of which an insect consists, comprehending that portion which is situated between the head and the abdomen. The trunk includes the thorax, collar, sternum, and scutellum.

*Thorax*: a term indefinitely applied sometimes to the whole trunk, the scutellum excepted: in a stricter sense it implies only the dorsal part of the trunk, and may be considered as expressive of that portion of the superior surface which lies between the head and the base of the wings. Linnæus is not so explicit as could be wished in his definition of the word thorax; according to this author, it is "the back part of the breast," and "upper part of the trunk between the head and scutellum," yet it is evident, from the dissimilar structure in this part of the trunk in different insects, that the definition requires rather more precision. It is not unusual in the specific descriptions of insects, both by Linnæus and Fabricius, to read of "thorax beneath," and "lower surface of the thorax," for the under-surface of the trunk; though both endeavour to establish it as a principle, that the word thorax applies to the back or upper surface of the trunk only. The appropriation of suitable terms, by which a thorax consisting of one, or of several pieces, may be discriminated from each other, is desirable. In some the thorax is of a single piece, as in the orders coleoptera and hemiptera; in that of lepidoptera it comprehends several segments, and a similar structure is still more conspicuous to view in the order hymenoptera. The first or anterior segment of the thorax in those consisting of several pieces has been sometimes called the collar; but in admitting this, we must by analogy define the coleopterous and hemipterous orders of insects as having no thorax. This will be rendered plain, when we consider that in the latter kinds of insects the first pair of legs arises from what is usually understood by the lower surface of the thorax; the interior segment in hymenopterous correspond with the whole thorax in the former, for the first pair of legs arises from it exactly in the same manner. In the former the thorax of a single piece is immediately succeeded behind by the scutellum, while in the hymenoptera and lepidoptera a large plane of one or more joints intervene between this true thorax and the scutellum; and it is to this last mentioned dorsal space that the term thorax is assigned. Hence it is evident that the lan-

guage of entomology in this point is not altogether consistent; because what we denominate the collar in hymenoptera, is the thorax in coleoptera, and in coleoptera we find nothing analogous to the thorax of the other order, except the collar.

The thorax in those insects, which have that part consisting of a single piece, or the first segment in such as are of a compound nature, have the first pair of legs arising from the lower surface, and it is in this part that the muscles that move the head, as well as this pair of legs, are said to be contained. The thorax in different kinds of insects varies considerably in form, and affords very excellent generic and specific distinctions. Some are armed with spines, others denticulated, margined, &c.

*Pectus*.—The breast is the third segment of the body, or that to which the four posterior feet are attached, and which is longitudinally divided at the anterior part by the sternum. The wings in lepidopterous, and most other insects, have their origin or base in the superior part of the breast. The wings and elytra in the coleoptera and hemiptera deviate a little from this, as they are placed more immediately on the back, than in a lateral position; the breast contains the muscles that move the wings, and give action to the four posterior legs. This part is capable of being compressed and dilated, the alternate motion of which is very evident in some insects of the butterfly or moth kind, when held between the fingers. The power of compression and dilatation is supposed to arise from the action of some very strong muscles, which seem to approximate the dorsal and ventral surfaces. They are four in number on each side, and differ very much in colour and texture from the other muscles, being reddish yellow, and extremely loose. It has been conjectured these muscles may assist the motions of the organs of flight.

*Sternum*, or breast bone.—By this term entomologists define that portion of the middle part of the breast which is situated between the base of the four posterior legs. This piece terminates insects anteriorly in a somewhat acute point, in others it appears rather bilobate, and in the far greater ends obtusely or in an obtuse lobe. There are few insects in which the sternum is remarkable, either from its magnitude or figure. In some of the coleopterous tribes, as hydrophilus and dytiscus, this part is most conspicuous.

*Scutellum*, or scutcheon (scutellum, Linn.) the lobe-like process, situated immediately at the posterior part of the thorax, in scutellate insects. The scutellum is not of the same form in all insects, yet its general tendency is towards a sub-triangular figure. In the coleopterous tribes it approaches nearest to this form; its deviations incline more or less to heart-shaped, with the tip pointing backwards. The same figure prevails in some of the hemiptera order. In the neuroptera, hymenoptera, and diptera, the triangular contour is still observable under various modifications, and most commonly with the posterior tip rounded off. Sometimes, as in several of the hymenopterous insects, the posterior end is armed with spines, or denticulations; this is, however, not usual, the scutellum in the far greater number of insects, whether terminating in a point, or rounded, is commonly unarmed. In point of size the scutellum is more variable than in figure; in some it is so small as almost to escape notice, merely forming a point at the extremity of the thorax, as we observe in certain kinds of the beetle tribe; in others it is very conspicuous; sometimes it is so large as to cover the middle of the back, and in others, as the scutellate kinds of cimices, and a few of the genus acrydium, it expands over the back, entirely concealing the wings and wing-cases, and covering the margin of the abdomen.

## ENTOMOLOGY.

*Abdomen.* is the last principal division, or posterior part of the body, and is connected with the breast, either closely, or at a distance, by means of a fillet. The abdomen is composed of annular joints or segments, the number of which vary in different insects. Each of these rings is pierced at the side with a single pore, which in some kinds are of conspicuous size, in others scarcely perceptible, and these are the orifices of the spiracles through which the insects breathe. The upper part of the abdomen is called by entomologists tergum; the inferior, or belly, venter. The opening at the posterior part of the abdomen is the vent, and the extremity in most insects contains the organs of generation: there are exceptions to the latter.

The total movement of the abdomen is not very obvious, except in insects which have that portion of the body pediculated, as in many of the hymenopterous genera. It has then a real joint, in which the first annulation is indented above, and receives a projecting process from the breast on which it moves. This joint is rendered secure by elastic ligaments, which have a considerable degree of force. Some muscles which arise within the breast are inserted into the first ring, and determine the extent of its motions. The partial motion of the rings is produced by very simple muscles, consisting of fibres which extend from the anterior edge of one ring to the posterior edge of that which immediately precedes it. When the dorsal fibres contract, the superior part of the abdomen being shortened, it turns up towards the back, but when the contraction takes place in the ventral or lateral fibres, the abdomen is inflected towards the belly, or directed towards one of the sides. The extent of the motion, however, depends upon the number of the rings, and their mode of junction. In the coleoptera, for example, the rings only touch each other by their edges, and the motion is very limited, but in the hymenoptera they are so many small hoops, which are incased one into another like the tubes of a telescope, so that scarcely half, and sometimes not above one-third, of their extent appears visible externally.

The form, connection, proportions, and appearance of the surface of the annulations of the abdomen, afford numberless specific distinctions; and so likewise do the appendices at the extremity of the abdomen.

The abdomen contains the intestines, the ovary, and part of the organs of respiration: it is affixed to the thorax, and in most insects distinct from it, forming the posterior part of the body. The abdomen is composed of rings or joints, by which means the insect can lengthen or shorten it, or even move it in different directions. The upper part of the abdomen is called tergum, the under part venter, the vent is in the posterior part.

*Tail.*—An appendage of any kind terminating the abdomen is usually denominated the tail. These appendages vary in figure considerably in different insects, and many tribes are totally destitute of them. They are supposed to be destined to direct the motion of the insect in flight, to serve for its defence, and for the deposition of its eggs. In some insects this tail is simple, (simplex,) and yet capable of being extended and withdrawn at pleasure. In others elongated (elongata). Some are setaceous (setacea) or bristle-shaped, as in the raphidia. Those termed trifeta have three bristle-shaped appendices, as in the ephemera. In some it is forked (furcata), as in podura. When it terminates in a pair of forceps it is called forcipata. In the blatta and others it is foliosa, or resembling a leaf. In the panorpa it is furnished with a sting, and is called telifera; this last may be more properly referred to the next.

*Aculeus,* sting, an instrument with which insects wound

and instil a poison. The sting generally proceeds from the under part of the last ring of the belly: in some it is sharp and pointed, in others serrated or barbed. It is used by many insects both as an offensive and defensive weapon: by others it is used only to pierce wood, or the bodies of animals, in order to deposit their eggs. In wasps and bees the sting is known to be retractile: in the scorpion fixed or immovably connected to the last segment of the body. In some insects it is the male only, and in others the female only, which nature has provided with this instrument: it is not frequently met with in both sexes of the same species; and the far greater number of insects have no such organ.

*Spiracles.*—These are the apparent orifices to the organs of respiration in insects, and which are known to many entomologists by the name of stigmata. The spiracles are a series of small apertures disposed along both sides of the abdomen: some few appear on each side the thorax, the remainder on the abdominal rings, every one of which is pierced on each side with a single aperture. Among the ancients it was generally believed that insects had not the power of breathing, and this they concluded because they have no respiratory organs, as in larger animals. The moderns are better informed; from the effects produced on insects by the pneumatic machine it is demonstrated, beyond dispute, that they do respire, though not in the manner of other animals. An insect placed in the receiver of this machine, upon the air being exhausted, becomes suffocated, and dies in a very short time; and the same result will be produced by closing the apertures of the spiracles with wax, oil, or other glutinous subjects, in a sufficient degree to preclude the passages of air through these openings, a fact which in itself may be regarded as conclusive, that these are the true organs of respiration in insects. They are also considered, and with much probability, as the organs of smell, as will be shewn hereafter.

Respiration being one of the most important actions in the life of every animal, it can be no matter of astonishment that great pains have been taken by naturalists to investigate the organs of breathing in insects; numberless facts contributed to prove its existence, but this being accomplished by means unknown in the other tribes of animals, it became an object of the greater solicitude to explain the manner in which it was effected. Malpighi, Swammerdam, Reaumur, and Lyonet, are among the number of the earliest writers on this subject, and from their observations it appears, that in the caterpillar there are two air-vessels, called tracheæ, which extend throughout the whole length of the insect; from these proceed an infinite number of ramifications, which are dispersed in various directions through the body; but the principal are those which form a direct communication between the tracheal vessels and the openings in the sides of the body. Of these there are nine on each side placed nearly at equal distances, one extremity terminates in the orifice of the spiracle, and the other enters the principal tracheal vessel disposed nearest, or on that side of the body. These lateral or spiracular vessels seem calculated for the reception of air; they are of a cartilaginous nature, and when cut preserve their figure; they are constantly observed in a temperate state of moisture, and communicate in many insects in the form of considerable vesicles, at their junction with the principal tracheæ.

Some writers have imagined, that though the air entered by the spiracles into the trachea, it did not come out by the same orifice, but was expired through a number of small holes in the skin of the caterpillar, after being conveyed to them through the extremities of the finer ramifications of the tracheal vessels. Others supposed, that the inspiration

and expiration of air through the spiracula, and that there was no expiration of air through the pores of the skin. Experiments were made to ascertain the truth of these opinions, by plunging the caterpillars into water, or anointing them with fat and greasy substances, either partially or entirely. The number of small bubbles which are observed to cover the surface of their bodies when they are immersed in water, is said not to arise from the air included in them, and then proceeding from them, but to be formed by the air which is lodged near the surface of their bodies, in the same manner that it is about all other substances. To render the experiment more accurate, and prevent the air from adhering to the skin, before the caterpillars were plunged into water, they were brushed all over with a hair pencil, and after this, it is affirmed, that few air bubbles were found on their bodies when immersed in water. The latter experiments were made chiefly by Bonnet, in order to ascertain the truth of some opinions previously advanced by Reaumur.

A caterpillar, according to Bonnet, may be retained a considerable time under water, without destroying the principle of life, and will recover soon after being taken out of the water, when it has lain till all apparent signs of life have ceased. A caterpillar partially immersed in water, or with two or three of the spiracles remaining in the open air, does not become torpid for a considerable time. One caterpillar lived eight days suspended in water, with only two of its anterior spiracles in the air. During this time it was observed, that when the insect moved itself, little streams of bubbles issued from the spiracles on the left side; from this and other experiments, however, it appeared, that the anterior pair of spiracles, together with the posterior pair, are of the greatest use in respiration.

It has been remarked, that "when we consider the great solidity of the cases or cones of certain kinds of insects; it is not easy to conceive how they can live several months under the earth in spaces so confined, and almost impervious to the air. If respiration was absolutely necessary to their existence, and indeed if they did respire, the same situation seems to preclude a continuance of the operation, as the air would soon be corrupted, and unfit for the offices of life."

But though it is difficult to ascertain the respiration of some insects at certain periods of existence, except from its effects in preserving life, which from analogy and collateral circumstances we are assured must depend on this cause, there are others to whom respiration seems necessary in a very extraordinary degree. Many instances of this might be adduced; but in no tribe is this more clearly shewn than in those of the aquatic kinds. There are a number of the latter which are obliged to keep their tails suspended on the surface of the water for this reason, and in proof of which, if they be plunged entirely under water, they become agitated and uneasy, first endeavouring to escape and rise again to the air, or, if prevented, shortly fall to the bottom and die. Some aquatic beetles resist the trial for a considerable time, while their larvæ can support the privation of air only for a few minutes. A remarkable evidence of the same kind occurs in the larvæ of *musca pendula*, which, though they live in the mud at the bottom of the water, have the power of extending the tube of the tail to a great length, in order to elevate it to the surface of the water; and the extremity of it is furnished with a tuft of fine hairs, which preserves that part buoyant on the surface, while the creature remains in a state of quiescence. A similar verticillated organ is placed at the tip of the tail in the larva of *musca chameleon*, which also lives in the water; this is expansile or retractile at the pleasure of the insect; when at rest the expanded tail rests upon the surface of the water, the re-

mainder of the body being suspended in that element with the head downwards, and when it is inclined to descend, it has only to retract or close up the rays of the tail to effect its purpose; an expansion of the tail will again raise the larva to the surface.

Upon anatomical examination, it has been found that the body of this last mentioned larva contains two large tracheal vessels: these air-vessels extend from the head to the tail, terminate in the respiring tubes, and receive the air from them. The larva quits the water when the time of its transformation approaches, and enters into the earth, where the skin hardens and forms a case, in which the pupa is formed: soon after the change, four tubes or horns are seen projecting from the case, which some suppose to be the organ for communicating air to the interior parts of the insect: they are connected with little vesicles which are filled with air, and by which it is conveyed to the spiracles of the pupa. The larvæ of gnats, and various other little aquatic insects of the same kind, are furnished with small tubes that play on the surface of the water, and convey the air from thence into the body of the insect.

Nothing can be more evident than that insects do not respire by the mouth, like other animals. To determine the respiratory organs in insects, and also to ascertain in what manner this function of life is performed, has been an object of solicitude with many. The experiments made with this view are numerous and conclusive, the result demonstrating, beyond dispute, that the spiracles are the apertures through which the air is drawn into the body. This may be inferred from the writings of Swammerdam, Malpighi, Reaumur, Muschenbrök, Degeer, and many others, who treat at large on this particular subject.

These spiracles exist in every stage of life, in the larva and pupa as well as perfect state. They are visible externally as a small knob of a roundish or oval form, slightly elevated and perforated in the middle: the aperture is usually oblong or subovate, and is the orifice of the channel which communicates with the trachea, one of which is disposed lengthwise on each side of the body.

The extreme tenacity with which many insects retain life, while deprived of air, seems to indicate that they exist much longer without the benefit of this renovating fluid than most other animals; and that in certain cases they may endure a temporary suspension of the functions of respiration. But nevertheless every experiment tends to confirm the fact, that so far as respiration is necessary, it is performed only by means of these spiracles, the closing of which, to the total exclusion of the air, will at length destroy the vital principle.

Lyonet has observed, that although it is a general rule that every thing which lives respire, it is not perhaps without exceptions in insects. Many give reason to doubt of their respiration, at least in certain stages of their existence. "I took, for instance," says he, "some of those large cantharides of the willow, whose strong smell, though not very disagreeable, is felt at a considerable distance. I put them under a glass, where for a long time sulphur had been burning on a piece of copper made red-hot, that the sulphur might continue to burn in the midst of its own vapours; and although there arose so thick a smoke that it almost hid the insects from sight, they supported these vapours for more than half an hour, without suffering, that I could perceive, the smallest injury." Insects, we are aware, may live some time confined in this manner amidst the vapours of burning sulphur, but the instance adduced by Lyonet is still remarkable, for we have known the same experiment tried with these cantharides, in the result of which the insects died

## ENTOMOLOGY.

within the space of time mentioned by Lyonet; and if, instead of sulphur, we employ camphor, the respiratory powers cease, and life becomes extinguished in a shorter period.

This author argues, that from the solidity of the greater number of the cones made by the pseudo-caterpillars, and most of the ichneumon flies, it cannot be conceived possible how these insects should live several months under ground, in a place so close and impenetrable to the air, if they were to breathe in it. "Neither," says he, "would I maintain the respiration of chrysalids; at least one experiment convinces me there are some which do not breathe. I took the chrysalis of the sphinx ligustri, which being one of the largest is the most proper for experiments. It had, besides, the two anterior spiracles so open, that with a common magnifier I could see into the substance of its body, and observe a small vacuum between it and the cover. This made me hope, that if respiration took place in the chrysalis this would give me certain proofs of it. Two or three months before the perfect insect issued from its cover I dug it up, and covered several times, first one and then two, and afterwards successively, the whole of its spiracles with soap water. At each time I observed, for a considerable space, with the glass, the spiracles thus covered, to see if any bubbles of air were formed above, which would naturally have happened, had these spiracles served as conduits to the air in respiration; but with all my attention I could perceive none. Some days afterwards I repeated the same experiment, in a manner to me still more decisive. Instead of covering the spiracles with soap-water, I covered each with a little bubble of air, taken from the froth of the same water, that the air might enter and go out more freely. But my curiosity was not more gratified: these bubbles, which ought to have risen or sunk at each expiration or inspiration of the chrysalis, preserved constantly the same appearance, till their pellicle becoming dry, they burst. When the perfect insect had issued from this chrysalis, I took it up instantly, washed the inside of it, and observed at the spiracles little bundles, composed of a great number of very white threads, of which the longest were about two lines in length. These appeared to me the exuvia of the pulmonary organs. I blew on each of the spiracles with all my force, by means of a very slender tube, but my efforts could neither swell nor move any of those fragments of the vessels which were attached to them internally; but this must necessarily have happened, had the communication of the external air by these spiracles in the bronchiæ remained open, or had the insect, when inclosed in its chrysalis, been able to breathe through them. It may be inferred from this, that the chrysalis of sphinx ligustri lives for some time without respiration, and that its two anterior spiracles serve only to facilitate the evaporation of the superabundant humours, and to permit the external air to supply their place." Lyonet, however, admits, that it is not on the single experiment here related that the knowledge of the respiration in insects is founded; and that this experiment does not appear decisive. We have unequivocal proofs of the respiration of insects; a fact demonstrated beyond all doubt in numbers of the aquatic kind, and as to lungs, he says, we may assure ourselves that insects possess them without being at the trouble of dissection. The spiracles are called stigmata by the modern naturalists; stigmates of the French.

### Members.

*Legs.*—In all insects that are furnished with wings the pedes or legs amount to six, and never exceed that number; and the same is observable of the true feet in the larvæ of

those insects; the latter have spurious feet to a greater amount, but the true feet do not exceed six. The apterous tribe in this, as in other particulars, afford exceptions: those of the pediculus, pulex, lepidina, podura, and acarus genera have only six legs, and these are attached to the body in the same manner as in winged insects: the scorpio, aranea, and phalangium genera have eight; the cancer, if admitted, have as many; and in the oniscus, julus, and scolopendra, they are far more numerous, varying from ten or twelve to twenty, fifty, or even thrice that number.

The leg of an insect may be divided into four, or, more correctly, into five parts; coxa, the first joint, or haunch, at the base; femur, the thigh; tibia, the shank; tarsus, the foot; and unguis, the claw. Each of these parts is enveloped in a hard case of a horny substance, and varies in shape in different insects; the form of the feet in all the kinds being admirably adapted to their mode of life, and convenience of their motion. Some of these are distinguished by particular terms, as, cursorii, those formed for running (and which are the most numerous); saltatorii, those constructed for leaping; natatorii, those employed in swimming, &c. From the different conformations of these limbs, it is easy to recognize, even in the dead insect, the mode of life which the species is destined by nature to pursue. Those which have the legs adapted for running or walking have them long and cylindrical: the thighs of the leapers are remarkably large and thick, with the shank long and commonly arched, by which means they possess great strength and power for leaping: the legs are broad, serrated, and sharp at the edge, in those accustomed to dig in the earth; and such as are of the aquatic kind have the legs, especially the posterior pair, long, flat, and ciliated, or fringed at the edge with hair. The leapers are well exemplified in the saltatorial kinds of curculio; and the swimmers in the genera hydrophilus and dytiscus.

The coxa, or small joint at the base, connects the leg to the body, and moves in a corresponding cavity of the collar or thorax in the first pair, or breast in the two posterior ones. This part varies in form: in the cerambyx coccinella, and other tribes in which the feet serve for walking only, its shape is globular: such as require that the feet should have a lateral motion, and which is necessary to those that dig into the earth, have the coxa broad and flat; this is also observable in some of the aquatic beetles; in the dytiscus, the coxa of the posterior legs is consolidated with the trunk, and immovable; and in the blatta, lepisma, and others which walk very rapidly, it is compressed into a lamellate form.

There is more diversity in the form of the thigh than the coxa to which it is united. The articulation of these two parts is internal, and is produced in such a manner, that when the animal is in a state of repose, it is parallel to the inferior surface of the body. It is limited to a forward and backward motion, with respect to the first piece. The nature and extent of the motions of the thigh appear to determine its form. In those insects which walk much and fly little, as the carabus, cicindela, &c., the thigh has two little prominences at the base, which appear to be intended for removing the muscles from the axis of the articulation. Those which require strong muscles adapted to leaping have the thigh not only thick but greatly elongated, as in the gryllus and locusta tribes, the pulices, or fleas, &c. And in the scarabæi, scarites, and other coleoptera, and also in the mole cricket (acheta gryllotalpa), all which burrow in the earth, the thigh is moved with much force, and has an articulated surface corresponding to the flat part of the coxa on which it rests. This part is sometimes spinous.

Tibia, or shank, is the third joint of the legs, and moves in

## ENTOMOLOGY.

an angle, according to the direction of the thighs. The figure of this part depends essentially on the uses to which the habits of the insect require it to be applied; in the natorial kinds it is usually flat and ciliated, at least the tibia of the posterior pair, and in many others, as in a variety of the burrowing kinds of beetles, it is serrated. In the mantis genus, to which shanks of the anterior pair of legs serve as weapons of defence, they are broad, flat, and acute at the edge, and these they wield with dexterity in the manner of a sabre. The shank is more frequently serrated or spinous than the thighs.

The tarsus, or foot, is the fourth joint, or last portion of the leg, except the claw. This part consists in general of five joints: this is usually the number in the coleoptera, hymenoptera, and diptera; in some of these, however, and also in the hemiptera, there are only four articulations in this part of the leg, as we observe in *cerambyx*, *gryllus*, and others; in *libellula*, *forficula*, &c. three: in the anterior feet of mantis and napa only one; and in those of the nymphales family of butterflies none. The figure of the tarsus is more variable than any other portion of the leg, and is in a most singular manner adapted to the insect's mode of life. The articulations in such as walk on the surface of the earth are slender, those which burrow in the earth have them more robust. Many of those which inhabit waters have them flat and ciliated at the edges, as in the hydrophilus. Others are furnished with bristly tufts, or vascular fleshy tubercles, which enable them to move with security on smooth and slippery bodies in any direction; an admirable example of this presents itself in the common house fly, which "treads the ceiling, an inverted floor," with the same facility that other insects walk on the surface of the ground. An occasional difference in the number and form of the joints of the tarsus is sometimes observed in the two sexes of the same species. The motion of each joint of the tarsus is performed in a single plane, and is directed by two muscles in each joint, one of which is small, and placed on the dorsal surface, the other larger, and situated beneath.

Unguis, or claw, the termination of the tarsus; in the greater number of insects there are two claws attached to each tarsus: some have only one, and in others furnished with two, there is an intermediate process forming by this means three. An appearance similar to this is seen in the legs of the lucanus, but this, on minute examination, is found to be a distinct joint also, armed with a pair of claws, precisely resembling those which, more obviously from their size, appear to terminate the tarsi. It is considerably smaller, but as perfectly well defined.

Reaumur, Weifs, Borelli, and Cuvier, have published some curious remarks on the laws of motion observed in the legs of insects, some of which are very interesting. The relative proportion of the feet seems to determine, in a certain degree, the particular manner in which each insect moves either in walking or leaping. When, for example, the legs are all equal, the movement is uniform, but when short it is slow, and when long, it moves with rapidity. Those insects, therefore, which have the legs long, as in the phalangium, and some others, run very quickly: and, on the contrary, the acarus, pediculus, and those others, which have the legs short, are remarkable for the slowness of their pace. When the anterior feet are longest, as in certain *cerambyces*, their speed is retarded when moving on even ground, though, in climbing, this length of the anterior legs is an advantage. When the posterior feet are longest, they usually afford the insect the ability of leaping, as in the locust, acheta, and other families; but such a structure impedes its speed in walking; and does not always enable it to leap; the insects of the

leucopsis and chalcis genus, though their posterior thighs are very large and thick, are supposed to be incapable of this action. The latter inability is attributed to the great curvature of the legs, those insects which are truly of the saltatorial kind, as in the *gryllus* genus, being remarkably straight.

*Alæ*, or wings.—Wings, the organs appropriated to flight. These in different insects vary from two to four, and are attached to the lateral part of the breast, close to the lower margin of the thorax. They are placed to an equal amount, and in a corresponding situation on both sides of the insect, whether the number be two or four. Those insects which are furnished with only one pair of wings, have both of an uniform appearance and size. Such as have two pair most frequently differ, the first being larger than those behind: there is also a difference in shape, and very commonly a considerable variation in the spots, markings, and other particulars, notwithstanding the prevailing hues in all the wings may be the same. In general, the posterior pair is paler, and the marks obscure.

The wing properly so denominated should be distinguished from the elytra or wing-cases, those hard shelly coverings of the true wings in the alated kinds of coleoptera. These wing-cases, or sheaths, are often confounded with the wings; but they are really not wings from their structure or substance, nor do they answer the purpose of flight: they merely open to afford the true wing, concealed beneath, the power of expansion and motion, and close down upon the wing, when the insect is at rest, to preserve it from injury. Of this we have spoken more largely in describing the elytra. The semi-crustaceous wings of the hemipterous orders partake of an intermediate character between the wing-cases and wings, as already noticed in its proper section. The wings and elytra in some insects, and the wings and hemelytrous wings in others, are so intimately connected, that we conceived it requisite, in order to avoid misconception, to advert again to this circumstance.

A skeleton of nerves, more or less numerous, and differing exceedingly in disposition, placed between two thin and closely united membranes, constitute the true wing in insects. This conformation is very clearly exemplified in that description of wings which is usually termed transparent, as in the common house-fly and the bee. The true wing, by means of which the insect is enabled to fly, is always constructed in this manner, whatever may be its appearance externally, arising from a superficial covering of down, feathers, hair, or any other cause. The variety in the form and structure of the wings, in the number, figure, and disposition of the nerves, or the colours with which they are adorned, is infinite. The diversity in the disposition of the nerves is evident from a comparison of the simply constructed wing of the common house-fly (*musca domestica*) with the complex wing of the panorpa, or the ephemera, or the wing of the forficula (earwig), which consists of a series of single nerves, with the elaborately wrought lattice-work of the wing of the libellula. The whole of the lepidoptera tribe exhibit the superficial coating of feathers, down, or hairs; and upon the removal of these, the wings are found constructed exactly in the same manner as the transparent wings of the other tribes. A variation in the form of the wing, as well as its texture, is manifest throughout all the insect tribes of the winged kind. Those of the coleoptera have two membranous wings, which fold upon each other, forming a plait, or double at their external margin; which fold is accommodated by a peculiar joint in the main rib of the wing, and the peculiar disposition of the nerves in the middle of the wing contiguous. In the he-

## ENTOMOLOGY.

miptera the wings generally fold longitudinally, without any transverse double, so that in expansion these parts open somewhat like a fan: the forficula is an exception in this order, the wing in this genus being doubled across as in the coleoptera. The wings of the lepidoptera are neither doubled across nor folded longitudinally; they are entirely flat, and incapable of contraction and dilatation. In the papilio genus they are endowed with the power of erection, which is not the case in the phalæna genus, though occasionally observed among the sphinges; the phalæna have the lower wings concealed under the anterior pair, the latter being laid in a flat position over them. The wings of the lepidoptera are downy, and often decorated with very beautiful colours disposed in the most pleasing and varied manner. The neuroptera in general have the wings flat; this is not invariable: they are constantly membranaceous, and reticulated with nerves. In the hymenoptera the wings are membranaceous, generally flat, but sometimes folded, when the insect settles, as in the wasp genus. The dipterous order cannot be confounded with the preceding, as they have only two wings, without any wing-cases: they are membranaceous as in the former.

Insects of the dipterous family, bees, and various kinds of hymenoptera, and many others, possess the powers of flying in a more perfect degree than any class of animals besides; surpassing in this respect even the bird tribe. All insects that are furnished with wings have not an equal celerity of motion in the air; the movements of the wings in some insects is more circumscribed than in others. The muscles that move the wings are not yet very well ascertained: they are said to be situated in the breast, and to be of two kinds; the first of these are small and short, and are intended to extend or fold the wings, at the same time that they move them to and fro from the body; the others, which are somewhat longer, are calculated to produce these motions of elevation and depression which the wings perform, very striking examples of which are found in the two genera papilio and libellula. The wing-cases of the coleoptera are not moved, it appears, by the pectoral muscles like the wings.

The dipterous insects, when flying, emit a loud buzzing sound, occasioned, as it is believed, by the wings and balancers striking against each other. The noise of the cricket and locust is produced by the friction of the wings, or base of the wing-cases against the posterior edge of the thorax; and which is observed likewise to be the case with the cerambyx, leptura, and various other insects.

In all insects of the winged kind these organs present the greatest diversity, and afford characters both of genera and species less liable to fluctuation than common observers would conceive. The number, figure, construction, proportion, consistence, and texture of the wings have enabled naturalists to distribute insects into principal families with considerable precision; and their minor peculiarities of spots, marks, and colours, have furnished subordinate characters of the utmost utility in defining species. Linnæus derived much assistance from an attention to these parts; later writers have in many instances regarded them more closely; and in the further progress of the science, we are persuaded these parts may be consulted with much greater advantage still.

There are many terms at present in use, intended to describe the different kinds of wings, the principal of which should be understood by the student in entomology.

The wing in all insects is distinguished, with respect to its surfaces, into superior and inferior; that above is denominated the superior, and that beneath the inferior. In the

description of wings, the terms anterior, posterior, interior, and exterior parts, and sometimes the disk, occur very frequently. The anterior part or margin is that next the head; the posterior, that towards the vent; its exterior, that towards the outer edge; and the interior, that next the abdomen: the disk is the centre of the wing. These terms are not always applied with precision by entomologists: the base of the wing, next the point of connection to the breast, is sometimes called the anterior part; and in this case, every other part varies its name in a relative proportion: and this appears to be a correct method of describing the parts of a wing in its natural state, while the insect is at rest, with the wings down; but it applies only to those which dispose their wings longitudinally: it would be altogether inapplicable in describing a papilio, in which the wings are expanded and stretched forward; or in the libellula, which rests with the wings in the same position. The anterior margin of a wing is, therefore, generally understood as implying the costal edge, and which is so named because it is formed by the main rib that extends from the base to the tip of the wing.

The wings are called plicatiles, when they are folded at the time the insect is at rest; planæ, when stretched out their whole length without folds, and incapable, from the structure of their nerves, to be folded up; erectæ, such as have an erect position when the insect is at rest, the superior surfaces being brought in contact above the back, and the extremities sometimes meeting, as in the butterfly tribe; patentæ, those like the geometra family of moths, and most of the libellula, which have the wings expanded horizontally when at rest; incumbentes, such as cover in an horizontal manner the superior part of the abdomen, when the insect is at rest. These differ from deflexæ, in having the outer edges declining towards the sides, like the ridge of a house; reversæ are also deflexæ, with this addition, that the edge of the inferior wings projects from under the anterior part of the superior ones; dentatæ are those with the wings indented or scolloped; caudatæ, those in which one or more of the nerves of the posterior wings extends beyond the margin, and forms a process, such as occurs in the equites family of papilio, and the genus hesperia, and in a far more remarkable manner in phalæna argus; reticulatæ, those in which the veins or membranes of the wing form a kind of lattice-work, as in the genus libellula.

The colours (colores) are named in terms agreeably to their common acceptation; but according to the various forms of the spots, bands, streaks, &c. in which they appear on the wings, they have various significant appellations. Maculæ are spots; punctæ, dots; fasciæ, bands; strigæ, streaks; and lineæ, lines. Ocellus is a round spot, containing a smaller spot of a different colour in its centre. Stigmata is a term in the Linnæan language, introduced to signify a spot or anastomosis in the middle of the wing, near the anterior margin: this is conspicuous in most of the hymenoptera and neuroptera. Stigmata is a term also applied to the single or double kidney-shaped spot situated in the middle of the anterior wings in many of the moth tribe, in the noctua family, and in some of the bombyces. Several modern naturalists call the respiratory spiracles at the sides of the body in insects stigmata, the application of which may create confusion; stigmata, and stigma, ought for this reason to be admitted in the sense Linnæus intended: the spiracles bear already a name sufficiently indicative of their use and appearance, and do not require this alteration. Most of these terms apply only to the lepidoptera tribe, in the markings of whose wings the most beautiful colouring prevails.

## ENTOMOLOGY.

*Halteres*, poisers, or balancers, appendages peculiar to insects of the diptera order, and which, with sufficient reason, are deemed an essential character of that tribe. These poisers are two short, moveable, clavated filaments, placed one contiguous to the origin of each wing. They seldom exceed one-tenth the length of the wing, though in certain genera they are rather longer. The capital, or head, in which the filament terminates is either roundish, oval, truncated at the end, or compressed at the sides: in some insects its situation is directly under a small, arched, filmy scale, which also varies in size and form; and in several families is entirely wanting.

The exact purpose to which nature has destined these organs has not been hitherto ascertained in a very satisfactory manner. The most prevalent, and perhaps in some measure the most consistent, opinion seems to be, that they balance or counterpoise with the action of the wings, when the insect is in flight, in the same manner as rope-dancers exercise a pole to preserve their equilibrium. The diminutiveness of their size is a plausible objection to this idea. Others consider these as the organs of that vibratory sound which dipterous insects emit in flight: they compare the filmy scale to a kind of tambour, and liken the balancer to a drum-stick, which striking repeatedly upon it, they conceive must occasion this noise. In the conformation of the drum-like organs under the breast of some species of tetti-goniæ, this conception is fully realized; a sound is actually occasioned by similar means. (Vide *Donov. Inf. China.*) But with regard to the diptera, it is apprehended the sounds they emit in flight cannot be traced to this cause: in some we know it cannot, for the best of all possible reasons, namely, that though, like others of the same tribe, they have balancers, they have no scale to strike with them. It should be observed also, that this buzzing sound is observable in a vast number of insects which have no poisers or balancers, such as wasps and bees. The two genera, *asilus* and *bombylius*, have no scale, and yet the noise perceptible in their flight is louder than in most of those which have both scale and poisers, as in the *muscæ*, for example. Nor does this noise issue from the poiser, either by striking on the scale, or by any other means, as must be admitted, since it is known that if the poisers, or both poisers and scales, be cut off, the same sound continues to be heard from the mutilated insects as before.

The motion of these poisers, when the insect flies, is very lively: they are longest in the *tipula*, *diopsis*, and *asilus*; in *musca*, scarcely apparent, and accompanied by a scale of large size.

*Elytra*, or wing-cases, appertain to the coleopterous tribe: these are two in number, of a substance resembling leather, for the most part moveable, and opening by a longitudinal suture along the middle of the back. The *elytra* are extended or raised up when the insect is in flight. They do not appear to assist the insect in its flight; the muscles, by which they are connected to the body, have not their seat in the breast, like those of the true wings; and its movement in the air is accomplished by means of the latter, which are transparent, folded between the body and *elytra* when at rest, and expanded when the insect flies. Some have the *elytra* united, and may with more propriety be named *elytron*, for it consists only of a single piece marked with a longitudinal line superficially, instead of being divided by a suture; this is lifted up, or rather, the abdomen depressed downwards, to admit the passage of the wings laterally, when the insect is preparing for flight. Others furnished with *elytra*, or wing-cases, seem to render the term for these parts exceptionable; for in reality they have no

wings beneath them: the number of these, however, is not considerable, and they cannot employ their *elytra* as organs of flight.

The superior surface of the wing-cases is more or less convex, and the lower surface correspondently concave: the texture in some, as in some of the *curculio* and *buprestis*, so hard, that it is pierced with difficulty by means of a strong pin; in others so flexible, that they spring into their proper form immediately after being bent double. The proportions of the *elytra*, compared with the body, are various, their form dissimilar, and the diversity of their surface, arising from dots raised or depressed, protuberances, flutings, colours, and other circumstances, endless. These differences in the *elytra* furnish some excellent generical distinctions, and are still more extensively useful in constituting the characters of species. When the wing-cases are shorter than the abdomen they are termed *abbreviata*, unless they terminate in a transverse line, when they are called *truncata*; *fastigiata*, when of equal or greater length than the abdomen, and terminating in a transverse line; and *ferrata*, when the exterior margin towards the apex is notched or serrated, as in some of the *buprestis* genus. The appearance of the surface is variously distinguished; *spinosa* is the term implying that the surface is covered with sharp points or spines; *scabra*, rough; *friata*, marked with slender furrows longitudinally; *porcata*, with elevated longitudinal ridges; *fulcata*, with concave ridges, &c.

The want of appropriate terms for those kinds of wing-covers, which partake of a middle texture between the *elytra* and the wings; and also for those in which the characters of both are united, must be obvious in the present state of entomology. To the first of these no suitable name has been given: the French "*ètius molle*," and "*ètius presque membranaceux*," are not sufficiently expressive; the first is deficient in precision, and in the other there is too much latitude. Linnæus once proposed the term *hemelytra*, by which he intended to designate both kinds, whether, as in the *grylli*, those parts were of an intermediate substance between leather and membrane; or, as in *cimices* and *nepæ*, one half was coriaceous, and the remainder membranaceous. The term, in this general sense, could not be strictly proper; it was, notwithstanding, preferable to that of *elytra*, admitting the latter to be rightly applied to the wing-cases of the *coleoptera*; and we are therefore the more surprised it was not afterwards adopted by that naturalist, or some other substituted. So lately as the tenth edition of the *Linnæan Systema*, the word *elytra* is employed indiscriminately for the hard and stubborn wing-cases of beetles, the soft wing-covers of the *blatta*, and the membranaceous reticulated wing-covers of the *gryllus*, all which genera were included at that time in *coleoptera*; and by an oversight equally extraordinary, the half-coriaceous wing-covers of the *cimices*, the *nepæ*, and *notonectæ*, were then confounded with the delicate covers of the *aphis*, *thrips*, and *chermès*, under the indiscriminate title of wings. The distinction of *coleoptera* and *hemiptera* is rendered rather more clear in the last edition of that work, the *blatta* and *grylli* being removed from the former to the latter order; yet the application of the word *elytra* to the wing-cases of the *hemiptera* is not by that means rendered less improper. The difference in the conformation and consistence of the wing-covers in the two tribes is too evident to leave this a matter of doubt. But custom has so far sanctioned this impropriety, that our best entomologists to this period describe all these kinds of wing-covers under the name of *elytra*. Fabricius has not even attempted to correct this error in the *Linnæan phraseology*: he adopts the same term.

Among

## ENTOMOLOGY.

Among the principal differences in the form and texture of the elytra, some, at least, are very remarkable. In the beetle, or coleoptera tribes, these parts are coriaceous, very hard throughout, convex in form, and divided by a straight suture. Those of the cimex genus have the upper half only of a coriaceous texture, the lower half being soft and membranaceous, and the latter portion of one elytron is folded across the corresponding part of the other when the insect is at rest. The coriaceous half of the elytra in many species is as hard and tough in texture as the entire elytra in the coleoptera, and the membranaceous part as soft as in the hymenoptera and diptera. In the genera blatta, forficula, acheta, and others, the elytra is of an uniform substance throughout, somewhat resembling parchment; a similar texture prevails in the elytra of nepa, notonecta, and naucoris genera, but rather like the cimices, there is a distinction between the upper and lower portions, the first being of a firmer texture, and thicker than the other part. The fulgora genus, like the gryllus, affords examples of another kind, thick, membranaceous, and strongly reticulated elytra, divided in the middle by a longitudinal suture. In the tettigonia, another of the hemipterous genera, the elytra are often perfectly membranaceous and transparent in texture, though not in form resembling those of the hymenoptera and diptera; yet these are called elytra, and so likewise are the weaker and more flexible transparent anterior wings of the aphid, thrips, and chermes, for these two are included in the order hemiptera! From a due consideration of these decided differences, we cannot hesitate to admit that the term elytra is not applicable to all. In a treatise of this kind it might, perhaps, create confusion to introduce any other terms than those in common use; we only intimate our persuasion, that reformation in the language of entomology is necessary. In the formation of any new system, and which in the present state of science appears requisite, we may reasonably hope to see these and similar objections obviated.

In conclusion of these remarks, it may be mentioned that nature has herself pointed out certain discriminating characters in those parts called the elytra which do not seem to have been sufficiently attended to, and which not only relate to their figure and appearance, but likewise to their utility, or the benefit the insects derive from these organs. The wing-covers in the coleoptera do not, it is generally believed, in the least degree, assist the insect in flying; in the cimices, and others which have those parts of a more flexible texture, they do not materially aid its celerity of motion in the air; but in those which have the wing-covers completely supple, they concur immediately to its velocity in flight.

### *Sexes of Insects.*

The same difference of sex exists throughout the insect race as in most other animals. The sexes cannot be ascertained in the larva and pupa state, except in some few instances; but when they arrive at their last state, both kinds possess permanent characters, by which they may be easily determined: these consist in a comparative difference in their size, and vivacity of colour, form of the wings, bulk of the abdomen, shape and dimension of the antennæ, and various other external peculiarities.

In most insects the male is smaller than the female, their comparative difference varies considerably in different species. In the lepidopterous tribe the female is only perceptibly larger than the other sex in general; in the ant it is six times larger than the male: in the coccus twelve or fifteen times, and in the termites the female is at least two hundred times larger than the male. This latter sex is commonly

decorated with colours more lively and brilliant than the females, a distinction observable in a very remarkable degree in many of the butterfly tribe, the males of which are very beautiful, and the females obscure. There is also some difference in colour between the two sexes in some coleopterous insects.

Many of the larger tribes of beetles (geotrupes) present a wide dissimilarity in the conformation of the two sexes: in the males the head is embellished with one, two, or more distinct and prominent horns, and which, in a number of species, are very considerable in size: these are entirely peculiar to the males; the head of the female has only a few slight protuberances instead of horns, and is sometimes even destitute of them.

In the moth tribe the antennæ of the male are almost invariably larger or more deeply pectinated than in the female, and this difference may be traced from the broad feather antennæ of the largest bombyces, to the setaceous antennæ of the noctuæ; however slightly the antennæ of the male appear pectinated, those of the female will be found still less so. The abdomen in this order is also smaller than that of the female. The colours of the wings also differ amazingly in the two sexes, of which phalæna humuli (Linn.) affords a very striking example, the wings of the male being of a beautiful snowy white; that of the female bright yellowish, with orange spots.

Another distinction, but which is not a general character, consists in the female being apterous, or without wings, the male being furnished with those organs of flight. Among the coleoptera we find the lampyrus of this kind; in the hemiptera the blatta; among the moth tribe, phalæna antiqua, gonostigma, brumata, &c. These wingless females are indeed so much unlike the other sex, that no one unacquainted with insects could believe them to be of the same species. The females of these lepidopterous insects are not entirely apterous; they have four very minute wings attached to the thorax, in the same place as is occupied by the base of the wings in the other sex, otherwise they resemble an apterous insect. In the aphid tribe the male has sometimes wings, and is sometimes without; and the female, it is said, differs in the same manner.

These are the principal external characters, by means of which the two sexes in insects may be discriminated.

### *Generation.*

That general law of nature which prevails among the larger tribes of animated beings, and ordains an intercourse of the two sexes as indispensable to the production of their young, does not regulate the multiplication of all insects: there are some singular deviations to the contrary. The doctrine held by the ancient sages of Egypt, that in certain insects both sexes are united, is perhaps inadmissible: we ought not to speak with too much confidence on this subject, notwithstanding the assurance of Linnæus, that there are no hermaphrodite insects. The observations of naturalists leave us in no uncertainty with respect to another order of beings, namely, those which belong to neither sex; and indeed the existence of these is demonstrated daily in every hive of bees.

The mysteries of generation are only in part unveiled to the philosophical enquirer. Some leading points appear equivocal, and remain inexplicable. This is the case with larger animals, where we have external circumstances to direct our judgment. With respect to insects, in particular, the history of their generation, in certain instances, at least, is more obscure. Many of them, like the larger animals, produce their young in consequence of an immediate union.

## ENTOMOLOGY.

of the sexes. But among the numerous families which compose this extensive class of creatures, there are some deviations from this ordinary course of nature, and these partaking of incidents so remarkable, that no positive and uniform conclusion of their mode of increase can be laid down. The notions entertained by some philosophers in the middle ages, that insects are the offspring of corruption and putridity, have no foundation in reason or analogy. It is impossible to conceive that organized bodies, possessed of life, and endowed with sensibility, can owe their origin to chance. But beyond this we are authorized in the belief of circumstances, that militate very strongly against established opinions. The course of generation and mode of increase, observed in certain tribes of insects, have no parallel among those of the larger kinds of animated beings: we need only mention a few particulars of the aphides in support of this.

Of the aphid genus there are not less than seventy species known, and the females of every one of these, so far as it has been possible to investigate their manners, are capable of producing their young without the concurrence of the male sex! A female aphid, brought up in the most perfect seclusion from the very instant of its production from the egg, will in the course of a few days be found in the midst of a numerous family of females only, brought forth alive. An individual taken from these, or even selected at the moment of its birth from the brood, and kept alone, will in a short time produce another brood, and in like manner a repetition of the same experiment will be again attended with the same results.

It would be only a natural inference drawn from the above mentioned circumstances, that in the same individual of this kind the two sexes must be united. This we know is not without example in the inferior order of animals, the greater part (we shall not say the whole) of the vermes tribe being probably of this description. Such is not apparently the case however with regard to the aphid; the real truth appears still more astonishing. To render these fertile, the intervention of the male seems to be requisite in autumn, and hence the power of impregnation devolves down to the tenth, or, as some naturalists affirm, to the twenty-seventh generation. The eggs of the first, or parent brood, are laid in autumn, these hatch in the ensuing spring, and this fertile produce perpetuate the race through many generations till the autumn following; every brood, after those hatched in spring from the egg, being viviparous.

The generality of vermes are believed to unite the two sexes in the same individual, and thus possess the power of self-production. Later observations seem to prove, that most animals of this tribe have both male and female organs, but that the union of two individuals are still requisite, each performing at the same time the office of male and female, and by this reciprocity of their functions both become fertile. Among the cancri, which Linnæus considers of the insect race, we are assured some monstrous lusi have been observed, in which the organs of both sexes were apparent; but probably these might not possess the ability to perpetuate their natural race. These we pass over therefore for the present as irrelevant. There is no insect, perhaps, such accidents excepted, in which the two sexes are united. We advance even this with caution, because there is reason to imagine the contrary in certain instances. From our own observation we are persuaded that some few at least of the supposed vermes are the larvæ of genuine insects. Let us for a moment imagine these larvæ to be really vermes! And let us farther conceive that these larvæ, like the true vermes, are

of the hermaphrodite kind! What an extraordinary deviation from the usual course of nature would such a prodigy present!

Here, however, be it explicitly understood, that we do not assert the latter part of this observation as absolutely certain. Such an assertion is countenanced by no opinion except our own, and such opinion ought not to be advanced without being at the same time supported by argument and proof, the production of which would extend the limits of our observations very far beyond our present design. It is only our wish to intimate at this time, that there are certain animals of the supposed vermes, and which are described by Linnæus and others as appertaining to this class, which are in reality the larvæ of insects; and that we are not without suspicion that some of these larvæ are fertile, and produce an increase in a manner not very clearly known, before they assume their final form. Among the supposed vermes of the marine kind, the larvæ of certain coleopteræ will perhaps be recognized. These are simply larvæ, and apparently destitute of any sexual functions till they arrive at their last state. Some of the fresh water larvæ, mistaken for vermes, are in all probability of the same description. But have we sufficiently examined the intestinal vermes? Are any of those peculiar to different animals, or man, capable of producing young vermes, like themselves, and afterwards becoming insects? One fact may be important, and we state it upon the testimony of our own knowledge, that certain kinds of these supposed vermes, which infest the human race to the destruction of thousands in the age of infancy, are really no other than the larvæ of insects.

Linnæus affirms that no insect can form an union with the opposite sex, or propagate its kind till it arrives at the last state, and offers this as a proof that gryllus pedestris is not a pupa which its appearance implies, because it is found connected with the female. This observation of Linnæus is pretty generally correct, and it may be further added, that in the different states, prior to the perfect condition, there are no sexual organs, or at least none that are developed. This is the fact with regard to most insects, certainly not to all. Among the cimices there can be no doubt in our own mind from actual observation, that the semi-nymphs of certain species do unite with their mates, and afterwards become winged insects. We are not without suspicion that many of the grylli, like the pedestris, possess the same faculty, and are afterwards furnished with wings.

With respect to the insects of neither sex, or neuters, it should be observed that those appertain to species in which there are the two distinct sexes besides, as in the bee tribe. It is chiefly among the hymenopterous insects that we meet with these neuters; the formicæ afford examples of other insects of the same kind, and it is believed there are likewise neuters among the coleoptera. They are called neuters because they are of no apparent sex. Some have pretended that they are no other than females, in which the sexual parts are not yet developed. This cannot, however, be the fact; neither can they be of the male sex under the same disguise, because they are constantly dissimilar in their characters from both, and could scarcely be supposed, from their appearance in many instances, to belong to the same species they really do, had not this been ascertained by their production from the same brood with the two distinct sexes.

Of insects in general it may be observed, that the males and females of the same species are not unerringly faithful; they deviate occasionally from the path appointed by nature. This is most observable in the coccinella genus. These hybrid insects are conceived to be unfruitful; they resemble

the

the female in form, but in point of colours and spots have some resemblance to the male parent.

There is an accordance in the structure and situation of the sexual organs in insects, whether male or female, with those of larger animals, and their union is accomplished in the same manner. These organs are usually placed at the extremity of the abdomen. This is not constantly the case; there are insects, and among those the spiders, which have the male organs placed at the tip of the feelers, one at the extremity of each; every individual of these creatures being furnished with two. The female organ is beneath the abdomen. Another singularity is observable in the libellule (dragon fly), the males of which have the sexual organ situated under the breast, while that of the female is at the extremity of the abdomen. When in union they are seen flying in the air, the female under the male with her slender body incurvated, and the tip of the abdomen bent under his breast.

Except at the period of their amours the sexual organs of insects are not perceptible, those of the male at other times are drawn within the body. Their union in some species continues for a short time only; others remain in this state for hours, or even days together.

*Transformation of Insects.*

Most animals retain during life the form which they receive at their birth. Insects are distinguished from these by the wonderful changes they undergo. The existence of an insect partakes of two, three, or four distinct states, and in each of these differs most essentially in appearance, organization, and manners of living.

The ancients were not unacquainted with the singular metamorphoses of insects. Ovid has drawn many beautiful fables from this source. The songs of Anacreon afford certain passages to the same effect; and we might also mention others. An inquiry into the knowledge of the ancients in this respect might be interesting; but we cannot now pursue the investigation, as it would lead to digressions the limits of this article will not allow. Our ideas have been offered at some length in another place. (Donov. Hist. Inf. China.) We shall only observe for the present, that they were not unacquainted with the metamorphoses which certain insects undergo. Their poets wantonly intermingled fable with truth, to improve their allegories; but their historians were more correct, and seldom formed erroneous conclusions, unless deceived by specious appearances. In the sixteenth century, with the revival of learning and philosophical discussion, and from that period to the present, this subject has engrossed much attention. The labours of Swammerdam, Goedart, Merian, Malpighi, and others, contributed materially to its advancement in the first instance. Their discoveries induced others to regard the transformations of these curious creatures with attention; and hence, in the course of years, their history became pretty generally understood. Those who afterwards contributed most essentially to the improvement of this branch of entomological knowledge were Reaumur and Degeer. In the progress of time, other valuable works appeared in elucidation of the same subject. The most useful of these, perhaps, to the general reader, are those denominated "Entomologi Topographici," or such as relate to the insects, with their transformations peculiar to, or inhabitants of particular countries. Among the number of these may be mentioned the two works of Merian, "Erucarum ortus, Alimentum et Paradoxa Metamorphosis," and "Insecta Surinamensia." "Histoire abrégée des Insectes, qui se trouvent aux En-

virons de Paris," by Geoffroy; "Nauwkeurige Waerneemingen," &c. of Adniral; Roefel's "Insecten Belustiging;" Abbot's "North American Insects," by Smith; and Donovan's "Insects of Great Britain."

The changes through which the greater number of insects pass are from the egg to the larva, from the larva to the pupa, and from the pupa to the last or perfect state. Exceptions occur to this: for some insects are viviparous; the number of these is not considerable: and there are others of the apterous or wingless kind, which undergo no change, issuing from the egg in the perfect form.

*Of the Egg State.*

The egg, containing the insect in its smallest size, is expelled from the ovary as in oviparous animals. They are contained and arranged in the body of the insect, in vessels which vary in number and figure, in different species. The same variety is found in the eggs: some are round, others oval, some cylindrical, and others nearly square. The shells of some are hard and smooth, while others are soft and flexible. It is a general matter of observation, that eggs do not increase in size after they are laid: among insects we find, however, one exception to this rule, for the eggs of a species of tenthredo are known to become larger after being deposited. The shell is membranaceous, which admits of this dilatation.

The eggs of insects are of various colours; some are found of almost every shade of yellow, green, and brown, a few are red, and others black. Green and greenish are not unusual, and they are sometimes speckled with darker colours, like those of birds. Some are smooth, and others beset in a pleasing manner with little raised dots.

Insects are instructed by nature to deposit their eggs in situations where their young ones will find the nourishment most convenient for them. Some deposit their eggs in the oak-leaf, producing there the red gall; others chuse the leaf of the poplar, which swells into a red bladder: to a similar cause we are indebted for the knob, which is often seen on the willow leaf, and the three-pointed protuberances upon the termination of the juniper branches. The leaves of the veronica and cerastium are drawn into a globular head, by the eggs of an insect lodged in them. The phalæna neutria glues its eggs with great symmetry in rings round the smaller twigs of trees; others affix them to the surface of leaves; and again, others lodge them in the crevices of trees.

The gnat, the ephemera, phryganea, and libellula, hover over the water all day to drop their eggs: these hatch in the water, and continue there while in the larva and pupa form, quitting the water only when they attain the winged state. The mass formed by the eggs of the gnat resembles a little vessel, and floats on the surface. This insect deposits only one egg at a time; the first is retained by means of the legs, when dropped, till a second is deposited next to it, then a third, fourth, and further number, till the mass becomes capable, from its symmetry, to support itself upright. Many moths cover their eggs with a thick bed of hair or down, collected from their own body; others cover them with a glutinous substance, which, when hard, protects them from the ill effects of moisture, rain, and cold. The solitary bees and wasps prepare nests in the earth, hollow trees, or cavities in old walls, wherein they place a quantity of food for the support of the young brood, when they break from the egg. Some of the spiders carry the eggs on their back in a small silky bag. The ants are known to construct nests in the earth, in which their eggs are placed

placed with the utmost care. Some deposit their eggs in the larvæ of other insects, chiefly those of the moth and butterfly kind; and having passed through all their changes in their bodies, become what is termed the ichneumon fly. In the Lapland Alps there is an insect called the rein-deer gad-fly (*oes-trus tarandi*), the attacks of which are greatly dreaded by the rein-deer. It hovers all day over these animals, who betray every mark of fear; their legs tremble under them; they prick up their ears, and rush to the mountains covered with ice and snow, to escape from the fly, but often in vain; for the insect follows, and generally finds means to lodge its egg in the back of the deer. The worm hatching penetrates the skin, and remains under it in security during the winter; in the year following it falls out, changed to a pupa, and becomes a winged insect. The *oes-trus bovis* is an equal terror to oxen; the *hippobosca equina* to horses; and *oes-trus ovis* to sheep: the latter in-finuates its eggs into the head of those useful animals, through the nasal organs.

The nest formed by the female of *hydrophilus piceus*, for the preservation of their eggs, is altogether remarkable, and is described with much minuteness by Lyonet. This nest is whitish, its figure an oblate-spheroid, three-fourths of an inch in length, and its breadth two-thirds of its length; on the upper surface it is terminated by a lengthened horn-like process, an inch long, ending in a point, and of a brownish colour. In this nest the eggs are deposited, and left floating on the water till in due time they hatch, and the larvæ desert the little bark contrived for their preservation in the state preceding, committing themselves to the water. These coques generally float among reeds and duck-weed. The purpose of the conical projection is supposed to be that of sustaining the case in an upright position, when assailed by the wind: but this is mere conjecture; we may have yet to learn its actual destination. Another aquatic insect, (one of the *nepa* genus,) that inhabits the waters of China, exhibits a far more extraordinary instance of the parental care which the insect race evince for the preservation of their eggs. This diminutive creature, scarcely an inch long, and of a subrotund figure, with the upper and lower surfaces flattened, is seen at particular seasons bearing a large cluster of eggs on its back, which, though disposed as compactly as possible, by being placed on one end, and having the sides touching each other, cover no inconsiderable portion of the whole surface of the disk. In this manner they are conveyed by the insect, wherever it goes, till the larvæ hatch, and drop instinctively into the water; when the parent insect casts off the exuvia of the nidus, and resumes its former appearance. (Donov. *Inf. China*.)

Of all the productions of nature insects are supposed to be the most numerous and fertile. With the exception of fishes and crustacea, they are apparently the most prolific. Lyonet has offered a curious estimate of the increase of insects, taken from their eggs. From a brood of 350 eggs, which he obtained from a single moth, he selected 80. These, when arrived at their perfect state, produced 15 females; and hence he deduces the following conclusion. If 80 eggs give 15 females, the whole breed of 250 would have produced 65. These 65, if equally fertile, would have produced 22,750 caterpillars, among which there would have been 4265 females. These, in the third generation, by the same mode of calculation, must amount to 1,492,750 caterpillars. The number would have been still greater, if in the first instances a larger number of females had been selected.

*Of the Larva State.*

*Coleoptera*.—The larva of all the coleopterous tribes of insects is produced from an egg, in which the growth of the creature in an embryo or infant state may be easily traced some time previously to its birth. They are either of a heavy, slothful, and voracious disposition, as may be observed most commonly of those which pass their lives under ground, in putrescent substances, or the trunks of trees; or brisk and active, like the generality of those in the succeeding or hemipterous order. Among the coleopterous larvæ of lively manners we must rank some of the terrestrial kinds, which, though they live in the earth, are always found close to the surface, and affect particular soils; and those of sands, in maritime situations especially: to these we should add the inhabitants of the watery element, or those which, in the state of larva, are of the aquatic kind; and in short, all that are carnivorous: these being more remarkable for their activity than such as are destined by nature to feed on plants only. A succinct account of the larvæ belonging to a few of the principal genera, and a concise description of their manners, will be sufficient to afford an accurate idea of the modes of life pursued by the larvæ of coleopterous insects in general.

We know nothing from actual observation of the larvæ, from which the larger kinds of extra European beetles are produced: the transformations of the species *hercules*, *al-cides*, *actæon*, *atlas*, and *goliathus*, and a host of other gigantic animals of the same kind, (the largest of the insect race,) remain at present in obscurity. Yet we are at no loss to conceive what the appearance of such insects in the larva state must really be, so far as we already know their affinities; because, from analogy, we can conclude they must be similar, or at least, generally speaking, we may presume with safety they differ only in some slight degree. The transformations of the species *nasicornis*, a native of Europe, an insect of large size, and from its conformation possessing habits similar to some natural family of exotic beetles, will, for example, assist our conclusions as to those resembling it; and, in like manner, the transformations of other extra European kinds may be determined with some precision, from the known changes of those insects naturally allied to it, or, in other words, of the same natural family.

*Scarabæus nasicornis*, or, as it is sometimes called, the rhinoceros beetle, from the conspicuous horn placed erect on the head of the male, resembles an extensive family of *scarabæi*, the inhabitants of Asia and Africa. The larva is hatched from an egg of a roundish form. The body is like that of a thick and somewhat broadish annulated worm, of a pale yellowish-white colour, flattish on the belly, and with the skin much wrinkled. The lateral breathing spiracles are very distinct, the head is hard and scaly, and armed with powerful jaws; and the three anterior rings of the body are furnished each with a pair of scaly jointed feet. It is found in the earth and in hollow trees, and several times casts its skin before it changes into the pupa state. The larva of the cock chafer, another of the *scarabæi*, (*melolontha*, Fabr.) resembles this, except in being smaller: like the rest of its family it spends the greater part of the time, while it remains in the larva form, in the earth, where it subsists on the roots of plants. It is two, and sometimes three years in passing from the egg to the perfect state.

The stag beetles, (*lucanus*;) in the larva state, bear a strong similarity with the preceding; they reside chiefly in rotten wood. The larvæ of some *cerambyces* resemble these in being soft, and in having the head and feet scaly. It is

## ENTOMOLOGY.

the larva of an insect of this genus (*C. damicornis*) which is eaten, and considered as a delicacy in the West Indies. The species is a native of this and other parts of America, and it is credibly affirmed, on the best authority, that some people of fortune in the West Indies keep negroes for the sole purpose of going into the woods in quest of them, and scooping them out of the trees. Their general length is about three inches and a half, and their thickness that of the little finger. Dr. Browne, in his history of Jamaica, particularly describes this insect; he informs us it is chiefly found on the plumb and silk cotton trees; that they are commonly called macacos, or macokkos; and that the mode of dressing them, after opening and washing, is to broil them carefully over a charcoal fire. The epicures of these trans-Atlantic regions only imitate the epicures of antiquity: they also esteemed the larvæ of the beetle tribe as a delicacy, and introduced them to their tables.

Many species of that elegant tribe of beetles, the curculiones, are the offspring of larvæ, bearing some resemblance to the former: their body is covered with a wrinkled skin, their head with a scaly covering, and the three anterior rings of the body furnished each with a pair of feet. These infest plants of various kinds; some subsisting on the flowers, others the leaves, the roots, seeds, &c. One of these, the larva of *curculio palmarum*, deserves notice for the same reason as that of *cerambyx damicornis*. This larva is about two inches long, and of an oval shape. It lives in vast numbers in the middle of the trunk of the young palm trees, and feeds on its juices. These trees are sometimes cut down, when about the height of a man, and the tenderest part of them eaten; the worms are also taken care of, being considered as highly agreeable food when roasted.

The larvæ of the coccinellæ have the body long, annulated, and furnished with six feet; they run briskly over plants, and feed chiefly on plant lice. The larvæ of the genus *cassida* are generally found under the leaves of plants on which they feed, to which they adhere by means of their lateral spines, and a bristle at the end of their tail. They form a kind of umbrella with their excrement, under which they are sheltered from the sun and rain. The larvæ of the cicindelæ are soft and white, long six-footed, and have a brown scaly head. These creatures employ great address to entrap their prey: like the lion ant, in some degree, the larva lurks in a round perpendicular hole in the ground, with its head at the entrance, to draw in and devour whatever insects come within reach. The larvæ of dermestes live in leather, fur, and other similar substances, to which they do considerable mischief. The larva of the *ptini* insinuates itself into wood, and destroys it.

That similarity in exterior characters, which we observe so prevalent in the perfect state of all coleopterous insects, whether of the terrestrial or aquatic kinds, is not apparent in the larvæ of those two natural tribes: they are in this state altogether remote, and have no greater analogy in their conformation than in their manners of life, or the elements in which they exist.

The larvæ of the dytisci constitute a link of beings closely allied to some of the neuroptera; and this resemblance is so remarkable, that certain species of dytisci and hydrophili in that state differ more from each other than they disagree with the larvæ of the libellula; these latter presenting creatures of an intermediate character, and which, to an ordinary observer, would seem to unite them. Thus, the larva of *libellula grandis* more closely corresponds with those of *dytiscus marginalis* or *punctulatus*, than the latter with *dytiscus caraboides*; and in external aspect the affinity of the

larva of *dytiscus caraboides* may be even stronger towards that of *ephemera marginata* or *hemerobius lutarius*, than to either of the former. There is certainly a difference between these in the structure of the jaws, &c.; but we speak only of those obvious characters and general appearances which first excite attention.

*Dytiscus marginalis*, the species before mentioned, is common in many stagnant waters; and, from resembling the shrimp in some distant degree, bears the name of *squilla aquatica* in the writings of Mouffet and Aldrovandus. It measures, when full grown, about two inches and a half in length, and is of a pale yellowish-brown colour, and very transparent. The head is large, somewhat flattened, and furnished in front with a pair of very strong curved forceps, which, when magnified, are found to be perforated at the tip: these are the instruments with which it seizes upon its prey, and sucks its animal juices. The legs are slender and small in proportion to the body; the tail terminates in a trifurcated process, ciliated at the margin. This larva is a fierce destructive creature, and not only commits vast depredations among the weaker kinds of water insects, but preys also on the fry of fishes, and is for this reason highly injurious in fish-ponds. It is supposed, like some others of the same genus, to remain two years in the state of larva. *Dytiscus cinereus* is produced from a larva somewhat similar, but remarkable for the length of the legs: its habits are the same. *Caraboides* is an hydrophilus, having the antennæ clavated instead of filiform; the body of the larva is shaped like the former, but on each side is a single series of plumose branchiæ, or breathing organs, like those observable in the larvæ of *ephemera marginata*. In the first stages of growth this larva is fuscous; when full grown, the posterior part is greyish and rather pellucid. The gyrius is another aquatic genus, and, from its form in the perfect state resembling the dytisci, has been supposed similar in that of larva; an argument, as already shewn, not always admissible. From the representations given by some authors, it is not unlike that of *H. caraboides*, in the species natator, only of a more elongated form, and having four ciliated appendages at the posterior end.

*Hemiptera*.—The larvæ of all hemipterous at present known are furnished with six legs, antennæ, and organs of the mouth, as in the perfect insect from which they originate; and agree with them in most other respects, except in being entirely destitute of wings. The larvæ of the mantes are carnivorous; those of the grylli feed on plants and farinaceous matter; the nepæ are aquatic, and subsist on water insects; the cimices, inhabitants of the land, and a most extensive tribe, are entirely carnivorous, and like that odious and well-known insect of the same genus, (the common bug,) derive their sustenance from the blood and juices, extracted by means of their proboscis, from the bodies of other animals, those of the largest kinds, and man. not excepted.

*Lepidoptera*.—The caterpillars of the butterfly, sphinx, and moth tribes form a very numerous series; and these, from a variety of concurrent circumstances, have been more particularly observed than any others. The greater part of those lepidopterous insects which come forth in the spring or summer perish or disappear at the approach of winter. There are few, the period of whose life exceeds that of a year. Some survive the rigours of winter from being concealed under ground, and others remain hid in the bark of trees, or in the chinks of old walls, but the proportion of those which out-live the inclemency of the winter season is very inconsiderable, unless it be those in the egg state. Those which

## ENTOMOLOGY.

which are hatched in the autumn, and live under ground or in other places of security during winter, usually come forth in the spring, take proper nourishment, and undergo their several changes to the perfect state. The eggs, which have been carefully deposited by the parent fly in those places where they could remain in the greatest safety, are also hatched in general by the genial influence of the spring, and the infant brood called into life and action.

All caterpillars are hatched from the egg, and when they first proceed from it are generally small and feeble, but grow in strength as they increase in size. The body of the caterpillar consists of twelve rings; the head is connected with the first, and is hard and crustaceous. No caterpillar of the moth or butterfly has less than eight, or more than sixteen; those which have more than sixteen belong to some other order of insects. The six anterior feet, or those next the head, are hard and scaly, pointed and fixed to the first three rings of the body, and are in number and texture the same in all lepidopterous larvæ. The posterior feet are soft, flexible, or membranaceous; they vary both in figure and number, and are observable only in the caterpillar state, the perfect insect having only six feet, the rudiments of which are the six anterior scaly feet before-mentioned. These spurious feet are either smooth or hairy, soft to the touch, or hard, like shagreen. On each side of the body are nine small oval apertures, which are considered as the organs of respiration, and are called spiracles. The head is covered with a shelly substance, and on each side are five or six small black spots, which are supposed to be the eyes. Some caterpillars grow to a very large size.

The caterpillar, whose life is one continued succession of changes, often moults its skin before it attains its full growth. These are the more singular, because when it moults it is not simply the skin that is changed; for we find in the exuvia the skull, jaws, and all the exterior parts, both scaly and membranaceous, which compose its upper and under lip; its antennæ, palpi, and even those crustaceous pieces within the head, which serve as a fixed basis to a number of muscles; we also find in the exuvia the spiracles, the claws, and sheaths of the anterior legs, and in general the traces of all that is visible in the external figure of the caterpillar.

The change in the caterpillar is effected by the creature withdrawing itself from the outer skin as from a sheath, when it finds itself incommoded from being confined within a narrow compass. But to accomplish this change is the work of some labour and time. Those caterpillars who live in society, and have a kind of nest or habitation, retire there to change their skin, fixing the hooks of the feet, during the operation, firmly in the web of their nest. Some of the solitary species spin at this time a slender web, to which they affix themselves. A day or two before the critical moment approaches, the insect ceases to eat, and loses its usual activity; in proportion as the time of its change approaches, the colour of the caterpillar declines in vigour, the skin hardens and becomes withered, and is soon incapable of receiving those circulating juices by which it was heretofore nourished and supported. The insect is now seen at intervals with its back elevated, or with the body stretched to the utmost extent: sometimes raising its head, moving it from one side to another, and then letting it fall again. Near the change the second and third rings are seen considerably swollen. By these internal efforts, the old parts are stretched and distended as much as possible, an operation attended with difficulty, as the new parts are all weak and tender. However, by repeated exertions, all the vessels which conveyed nourishment to the exterior skin are disengaged, and cease to act, and a slit is made on the back, generally beginning

at the second or third ring. The new skin may now be just perceived, being distinguished by its freshness and brightness of colour. The caterpillar then presses the body like a wedge into this opening, by which means it is soon torn down from the first to the fourth ring: this renders it large enough for the caterpillar to pass through.

The caterpillar generally fasts a whole day after each moulting, for it is necessary that the parts should acquire a certain degree of consistency before its organs can perform their ordinary functions. Many perish under this operation. The caterpillar always appears much larger after it has quitted the exuvia than before; for the body had grown under the old skin till it was become too large for it, and the parts being soft they were much compressed, but as soon as this skin is cast off, the parts distend, and with them the new skin, which is yet of a flexible and tender texture, so that their increase in size at each moulting is considerable. Some caterpillars in changing their skin alter very much in colour and appearance, sometimes the skin from being smooth becomes covered with hair, or spines, or tubercles, and others that are in one stage hairy, have the skin smooth in the next. No sex is developed in the caterpillar state.

The caterpillars of lepidopterous insects seem destitute of all means of defence, and are the prey of birds and other voracious creatures. Nature has not, however, left the whole tribe in this defenceless state, some kinds are armed with strong and powerful spines disposed in a verticillate manner round the annulations of the body, and which, if they be insufficient to annoy others, serve at least, in some measure, as the means of self protection. There are others, chiefly the inhabitants of the warmer climates, whose bodies present an armament of spines not unlike that of the hedgehog or porcupine, and these placed in such a formidable manner, as must either forbid the approach of other small creatures, or punish their temerity. Some few of the North American species are of this description. In others, we see the rings tuberculated, and every tubercle beset with ramose spines, the branches of which intertexting with each other, form an almost impenetrable net-work of spines. Others again are thickly clothed with spines and hair intermingled, which may be sufficient to guard them against the attack of some of their inferior enemies. Some species with the body covered only with a thin skin, and therefore apparently exposed to the annoyance of every other, has the jaws so powerful, and the disposition so ravenous and fierce, that they constantly attack, and most commonly with success, the larva of other species much larger than itself. At the extremity of the body in the larva of the sphinges, is a remarkable recurvate spine or horn, formidable in appearance, but harmless in its nature, and which is vulgarly supposed to be its weapon of defence. These insects, or at least some of them, are not, however, without the means of annoyance, for it appears they possess the ability of discharging from their mouth or vent a fetid liquor, the scent of which, should it fall on the skin, cannot easily be removed even by washing, and which may be supposed powerful enough to repel other insects. This ability in the sphinx tribe of caterpillars is admitted on the authority of some credible authors; the like circumstance is more commonly observed in the larvæ of some species of tentredo.

The caterpillars of many insects of the butterfly tribe feed close to the ground, or under the surface, subsisting on the lower parts or roots of plants; and for this reason many kinds are seldom seen, and others remain unknown. The larvæ of the sphinx kind live chiefly on the leaves. Those of the scia genus are usually denominated internal feeders, or such as reside in hollow cavities, which they form.

in the trunks or branches of trees, the substance of which also affords them nourishment. Many of the moth tribe are of the same kind, and have the same habits; others eat the leaves of different plants, and a few of the smaller sorts feed on woollen, paper, and other substances, not of a vegetable nature. Some of the lepidopterous caterpillars are solitary, others live in society.

*Neuroptera*.—The larvæ of neuropterous insects are carnivorous, and in the vivacity of their manners exhibit a very striking contrast with those of the generality of insects. They are nearly all of the aquatic kind, passing their whole life, till they assume the winged state, in the water; and are distinguished for the peculiar address with which they constantly wage war, not only against every other diminutive inhabitant of their natural element, but also against each other. These larvæ are hexapode, or furnished with six feet of a scaly nature, and having the head protected by a similar substance.

The libellulæ, or dragon-flies, form an interesting genus of the neuroptera order, and the habits of their larvæ illustrate, in the strongest manner, the nature of these aquatic creatures. The egg, when deposited by the parent in the water, sinks to the bottom, and remains there till the young insect has acquired sufficient maturity and strength to burst from its confinement. The larva, at first small, increases to nearly half the size of the perfect fly, by changing its skin at different intervals like the caterpillars of moths and butterflies. The appearance of the little cases containing the rudiments of the wings, at the lower margin of the thorax, denotes its change to the state of pupa. The head of this larva is exceedingly singular, being covered with a mask extending over the whole of the fore part of the head, with cavities in the interior surface to suit the different prominences of the face to which it is fitted with perfect neatness. Its form is triangular, growing smaller towards the bottom: in the latter part there is a knuckle which fits a cavity near the neck, and on this part it turns as on a pivot. The upper part of this mask is divided into two pieces, which the insect can open or close at pleasure, and it can also let down the whole mask, should occasion require. The inner edges of these two pieces are toothed like a saw, and serve the animal as a pair of forceps to seize and retain its prey. This is the general principle on which these projecting forceps are constructed in the larva of the libellulæ; they differ in shape in the several species, but uniformly act in a similar manner.

These animals generally live and feed at the bottom of water, swimming only occasionally. Their motion in the water can scarcely be called swimming, it is accomplished by sudden jerks repeated at intervals. This motion is not occasioned by their legs, which at this time are kept immoveable and close to the body: it is by forcing out a stream of water from the tail that the body is carried forward, as may be easily perceived by placing them in a flat vessel, in which there is only just water enough to cover the bottom. Here the action of the water squirted from their tail will be very visible; it will occasion a small current, and give a sensible motion to any light bodies that are lying on the surface. This action can only be effected at intervals, because after each ejaculation the insect is obliged to take a fresh supply of water. The larva will sometimes turn its tail above the surface of the water, and force out a small stream, as from a little fountain, and with considerable force.

The larvæ of the ephemere, another of the neuropterous tribes, differ in various particulars from those of all other insects: its length, in the larger species, about an inch; the form rather long, and sub-cylindrical, tapering a little towards the tail: the head is furnished with antennæ, trunk

with six legs, abdomen with several sinny plumes each side, and the tail with three long processes. They live in the water, where earth and clay, it is affirmed, form their principal nourishment for the space of two or three years, the time they consume in preparing for their metamorphosis, and which is accomplished in a few moments. The larva, when ready to quit that state, arises to the surface of the water, and instantly casting off its skin becomes a pupa. This is furnished with a kind of wings, by the assistance of which it escapes to the shore, and there settling, in the same moment, quits a second skin, and becomes the perfect fly. In this state, which has been so long preparing, the pleasures it enjoys must be very sensible, if they are lively in proportion to the shortness of their duration, the insect celebrating its nuptials, producing the fruit of them, and dying within the space of a few hours; the vital principle, though so evanescent in the complete insect, is extremely tenacious in the larva.

The phryganæ, a genus of this order, very much resembling, in general appearance, certain families of the moth kind, are the offspring of aquatic insects, not much unlike the larvæ above described; only that instead of inhabiting the waters in a defenceless state, they constantly live in small cylindrical cases of their own construction, which they drag after them in the water wherever they go. These cases are tubular and open at both ends: externally they are formed with small bits of reed, gravel, small shells, and other substances curiously cemented together, and lined with fine silk. The animal never quits its habitation till it becomes too small for its body, when it constructs another. Like the hermit crab, when it is desirous of moving from one place to another, the animal advances the fore-part of the body out at one end of the tube, so as to admit the free use of its legs, which are six in number, and placed contiguous to the head, and by this means it is able to crawl or walk with perfect facility at the bottom of the water. The body in most species is smooth, and the back usually furnished with a tubercle, which prevents the case from slipping too forward while the animal is feeding, and which serves also to retain the case more firmly to the posterior part of the body in the action of walking. These, in common with other aquatic larvæ, are frequently used by anglers as bait, and are called cadew-worm, stone bait, or cod bait, and in the perfect state is known by the name of spring fly. The larvæ of the phryganæ prefer running waters.

Those above-mentioned are the larvæ of the amphibious kinds of neuropterous insects; there are others which live only on land, and differ much from these both in appearance and mode of life. Those of the myrmeleon, panopa, hemerobius, and raphidia, are of the terrestrial order. They are carnivorous as well as the aquatic kinds, preying on other insects. The most extraordinary of these in their manners of life are such as have been denominated by naturalists the lion-ants, or lion-pismires (the myrmeleon of Latin writers). Of this genus there is nearly a dozen species, or, indeed, if we include the ascalphi which Fabricius removes from that genus, there are altogether sixteen species at present known. The larvæ of this family prey with the most savage ferocity on all the smaller kinds of insects: it is not, indeed, this disposition, so common to all carnivorous larvæ, that renders them remarkable, but the extraordinary and peculiar contrivances they adopt to ensnare their prey. We are best acquainted with the history of the species formicarius, the formica-leo of Linneus, and this may serve as an example of the genus, the habits of which, so far as we are acquainted with them, being alike in all, with this difference, however, in their predatory powers, that formicarius

## ENTOMOLOGY.

is one of the smaller kinds, and less capable, from its inferiority in strength and size, to commit devastation, than most of the extra European species, those of Africa especially.

*Myrmeleon formicarius* is found in France, Spain, and Germany, and is an inhabitant of sandy places. The egg is deposited by the parent insect in the sand, and this hatching produces a larva of an ovate form, armed with a long and powerful pair of jaws. The larva, as soon as produced, begins to exercise its talent of preparing a pitfall in the sand, by turning itself rapidly round, and which, when formed, is somewhat funnel-shaped, or rather concave, with a very small aperture in the centre under which the animal conceals itself with only its pincers advanced through the hole, ready to seize on any insect that may unwarily fall into the hollow. Sometimes the whole head is protruded through the hole, but when it lies in wait the body is always concealed under the sand. From the structure of this trap, such insects as crawl to the edge or sides are almost sure to fall in, and be devoured by the larva. But should the sides of the pit not give way, or the unfortunate insect appear to be able to make its escape, its merciless enemy immediately discharges from its head showers of sand, the repeated force of which is irresistible; the insect falls within reach of the larva, who, after sucking out its juices through the tubular forceps, by a sudden exertion throws the remains of its carcase out of the hollow to a considerable distance, and again, after repairing its den, renews its vigilance for prey. As the larva increases in size, it enlarges this cavity; at first it is only a slight depression in the sand half an inch in diameter, in its next stage it is increased to twice that diameter, and when the larva attains its full size is between two and three inches across. In the preparation or enlargement of its pit, when it grows to its full size, it shews much address: its operation commences by tracing an exterior circle of the intended circumference of the cavity, and continuing its motion in a spiral direction till it reaches the centre, thus marking each revolution in the sand like the impression of a large shell of the whorled kind, the breadth of each whorl corresponding with that of the insect's body; and which, in the circumference of the whole cavity, amounts to four or five circles. After having sufficiently deepened the cavity by a repetition of this motion, it smooths the sides into a regular shape, by throwing out the superfluous sand by means of its forceps, which, when closed, together with the head, forms a convenient kind of shovel for the purpose. The grains of sand thus discharged often fall to the distance of ten or twelve inches beyond the verge of its cavity. The depth of the cavity is usually equal to its diameter. The singular larva, whose manners of life appear so interesting when it has attained its full size, is about three quarters of an inch long, and has much the aspect of a large spider in the form of its body: its head and legs more nearly resemble those of the pediculi of some particular animals, and are very small, and in the structure and proportion of the jaws or forceps its character is peculiar, these being enormous. Its general colour is pale reddish, very prettily variegated with distinct marks and spots of deep ferruginous both on the back and belly; the whole is beset with a few hairs, some of which appear in tufts. It remains two years in the larva state; in the summer it is active, but it is torpid during winter; when full grown it changes into a pupa, the animal previously enveloping itself in a round ball of sand agglutinated and connected by a very fine silk, which it draws from a tubular process at the extremity of the body; with this silk it also lines the internal surface of the ball. The complete insect is furnished with four transparent spotted wings, and, like the larva, preys on insects.

*Hymenoptera*.—The larvæ of the teredines bear the nearest resemblance possible to those of some lepidopterous insects, and have for this reason acquired the name of bastard caterpillars, or false caterpillars; the spiral manner in which they roll themselves up is one character that seems to remove them from the true caterpillar, but they are more clearly distinguished by the number of feet, which, though varying in different species of both families, may be said to be constantly more numerous in the tenthredo genus than in any of the lepidoptera orders. The first have from eighteen to twenty-two feet; the latter never more than sixteen, including the spurious or posterior ones. These live chiefly on the rose and willow trees. The larvæ of the *firex* genus is cylindrical, and furnished with six feet, and the head rounded; they perforate wood, and frequently eat their way into the bodies of other insects, or their larva, and consume their vitals. These are the principal hymenopterous larvæ that are furnished with feet: the succeeding insects are destitute of those organs when in the larva state.

One of the most curious tribes of larva among the hymenopterous genera are those called the gall-flies; they are in no particular manner remarkable in appearance, but the effects they produce render them extraordinary. Every one must have observed those vegetable excrescences, of a globular form, which appear on the leaves and foot stalks of the oak at particular seasons of the year, and which in autumn have acquired the size of a cherry or a small plumb, its colour a bright red, and forming a pleasing contrast with the verdure of the leaves; these are the habitations formed by the punctures of the gall-fly, in which the eggs were deposited each singly in its globule by the parent insect, and each of those excrescences at this season, on being opened, will be found to contain a larva; a small worm of a cylindrical form and without feet. There are an amazing number of species of the gall-fly (*cynips*) that construct their dwellings, and subsist on the juices of the oak, and many others that attack in like manner the maple and the willow. The larva is found like a nucleus, in a small cavity immediately in the centre of each excrescence.

The manners of the ichneumon, as popularly described, are fully known, and the history of the ichneumon flies seems to accord in a peculiar degree with all that has been fabulously related of the former. They are entirely parasitical, and derive their sustenance, till they arrive at the perfect state, from the vital juices of other insects. Their eggs are deposited only in the bodies of other living insects, generally those of the caterpillar kind. The female, selecting her victim, fastens upon it, plunges her abdominal tube into the body, and, in despite of all resistance, maintains her hold till she has lodged her store of eggs. In the course of a few days the young larvæ, which resemble minute maggots, are hatched. These nourish themselves with the juices of the caterpillar, which, notwithstanding it affords sustenance to the parasitical brood, continues to move about, and feed till the time of its change into the chrysalis state, when the larvæ creep out by perforating the skin in various directions, and form little oval silken cases, the whole of which with the spinning forms an envelope to the withered remains of the insect from which they derived nurture. The latter inevitably perishes from the injury sustained; in a shorter or longer period, according to the species, the ichneumons appear in a perfect state. This parasitical family, when produced, are found to be either entirely of the winged kind, or to consist both of alated and apterous insects, the females in certain species being destitute of wings. These are, notwithstanding, perfect insects, as they never acquire those organs afterwards, and being besides, after an intercourse with

the other sex, in a condition to deposit fertile eggs, and thus perpetuate the breed. The apterous females attack caterpillars and other insects in the same manner as the winged kinds, and deposit their eggs in the living body.

So far as we are acquainted with the natural history of the sphex tribe, the larvæ of these are lodged in the bodies of other insects, in a manner similar to that adopted by the ichneumons, with this difference, that the sphex generally destroys the principle of life in those creatures it attacks, instead of leaving them to linger through a tedious existence of torture. These insects are very abundant in wood and hedges, and the larvæ feed chiefly on dead insects, in the bodies of which they are produced from the egg. Some species dig holes in the earth with their fore feet, in which they bury their dead insects, consulting chiefly of spiders and caterpillars, having previously deposited their eggs therein; these holes are carefully closed with earth or clay, through which the larvæ force a passage when hatched. The larvæ are vermiform. The manners of these insects is strongly exemplified in the species *sigulus*, a native of Upsal, and which is described by writers with considerable attention. This sphex inhabits the holes in old wooden partitions, abandoned by other insects, the interior of which the female cleanses by gnawing the surface of the cavity throughout, and prepares it for the reception of her victim, by placing a piece of clay in the bottom. She then seizes on a spider, which having killed, and flattened upon the clay, she next proceeds to the deposition of the egg, which is lodged in the dead body. This laid she closes up the opening with clay. The larva hatched from the egg resembles the maggot of the bee, and which, having devoured the food provided for it, spins itself a silken web, and changes to the pupa state. In this manner each female insect prepares several separate holes, in each of which a dead insect and an egg are deposited. The larvæ of wasps and bees are soft, without feet, and feed on the nectar and honey collected by the parent insects. The larvæ of the ants are also well known. The three latter mentioned families live in societies, and with those already noticed form the principal kinds of hymenopterous insects.

*Diptera*.—These larvæ vary much in different genera. Commonly they appear like a small worm, the likeness to which is heightened by the animal having no feet, and in some species by the head being soft, like the body. Others differ in having the head scaly. The larva of the oestri, or gad-flies, deposits its eggs in various parts of the bodies of cattle, which, when hatched, produce the most painful tumours. Some lay their eggs under the skin of cows or oxen, which they perforate for that purpose: others enter the intestines of horses by the vent; and others, again, deposit them in the nostrils of sheep. The larva of *oestrus bovis* is brown, and consists of eleven segments, with transverse rough interrupted lines. That of *equi*, known by the name of bots, deposits its eggs on the hairs of horses, and always on those parts which are most likely to be licked with the tongue, and are thus conveyed into the stomach. The eggs of *hæmorrhoidalis* are laid on the lips of horses, occasioning a titillation, which causes the animal, when attacked by it, to move its head violently, and gallop about with every symptom of distress: this larva is carried into the intestines like the former, and is voided with the dung when its period of change to the pupa state approaches.

In the genus *tipula* the larvæ are soft, cylindrical, and truncated at the head: these feed on the roots of plants. The larvæ of the different natural tribes, comprehended among the Linnæan muscæ, exhibit some very dissimilar ap-

pearances in form and habit. Generally, they possess a worm-like aspect, sometimes blunt at the anterior part, and acute behind, and at others pointed at both ends. Many live in watery places and devour insects; others feed on decaying animal matter, or on the juices of vegetables. The larvæ of *musca vernileo* preys on insects, and in its mode of entrapping its prey imitates the manners of *myrmoleon formicarius*, like that ferocious insect forming a circular den in the sands which it inhabits, and watching in an aperture at the bottom for the unwary insects that unfortunately wander too close to its cavity. But of all the peculiarities related of the musca tribe, nothing appears in any degree so extraordinary as the history of the larva of *musca tenax*, recorded on the authority of Linnæus, and sanctioned by that of Fabricius. The larva is represented as a brown maggot with a long tail, which latter is extensible, and consists of a double tube, the exterior annulated into numerous segments, and the interior slender and terminated by a circle of hairs, surrounding a spiracle. This maggot is seen in muddy stagnant waters, drains, and other similar places; and is, according to Linnæus, a frequent inhabitant of the turbid pulp used in the operation of paper making. Hence it is often in this state exposed to the action of the wooden mallets used in this process, as well as squeezed in the strongest presses, and yet it survives uninjured these seemingly destructive operations.

This circumstance is described in a paper entitled "*Miracula Insectorum*," inserted in *Am. Acad.* 3. p. 331, and though purporting to be the production of Emanuel Avelin, obtained the sanction of Linnæus. The same observation is confirmed in the "*Systèma Naturæ*;" and is repeated in this place as a most extraordinary trait in the history of this insect, without deeming ourselves in the least responsible for its veracity.

The tabani nourish themselves with the blood of horses and cattle; and some think the larvæ are aquatic, though Degeer asserts they live under ground. The larvæ of culices (gnats) are very curious in their conformation: the body consists of nine segments, which become gradually smaller from the head towards the extremity. The head is very large, and furnished on each side with a pair of pointed forceps, or hooks, with which it seizes its prey. The tail terminates in a tubular opening, at the tip of which are four ovate scales, two of which exceed the others in size. At the end of the body, near the tail, is a small elevated respiratory tube, which the creature frequently raises above the surface of the water, while the head remains suspended downwards. The colour of the larva is brownish, extremely pellucid, and its motions remarkably lively. The larva, when first hatched, is extremely minute, and in the space of fourteen days from its birth attains its full size, its length being then about half an inch. The painful sensation occasioned by the sting of the gnat, or, in other words, its sucking proboscis, is well known, and hence we are taught to consider the gnat as an insect subsisting only on the blood of other animals: this is not, however, the opinion of some naturalists, who, reflecting on the myriads of these creatures, with which every watery place is infested, conclude they could not find sufficient sustenance, unless they subsisted equally on the juices of vegetables and animals. Whatever may be the truth in this respect, the weapons of annoyance with which nature has furnished the larva indicate very clearly to us that in that state, at least, it is of the carnivorous kind. We shall lastly mention the *hippoboscæ*, a dipterous genus in the Linnæan system, and which, unlike those before adverted to, do not appear to have any larva; they are the produce of an egg which partakes of the two-fold

## ENTOMOLOGY.

fold character of being at the same time an egg and a pupa. The female, at distant intervals, deposits an egg, which in magnitude is nearly equal to the whole bulk of its parent's body: the figure of this egg is oval, with an excavated depression at the lower end; the colour, at its first exclusion, is milk white, except a large black spot on the fore part, from which it afterwards becomes brown, and then of a jet black, with a very high polish. This change in colour marks the progressive advancement of the insect inclosed towards its maturity of formation, the parts becoming gradually developed. The egg deposited in autumn acquires its deepest colour in the summer following, at which time the insect bursts from its confinement in the winged form.

*Aptera*.—No insect of this order, except the common flea, are supposed to undergo those successive changes which are usual in most other insects. They are almost entirely produced from the egg in their perfect form, and cannot therefore be said to have any larva. In the flea, however, the small worm which corresponds with the larva in other insects is clearly ascertained; and if we may place sufficient reliance on the evidence of certain naturalists, one or two more of the apterous genera exist for a short period in a state somewhat analogous either to the larva or pupa. Leeuwenhoek observed that the mite was oviparous, laying very small oval whitish eggs, from which proceeded the young animals, resembling their parents in all respects, except in the number of their legs, these being only six in number, instead of eight; and after they cast their skin another pair of legs appear, a fact that evidently implies two periods of transformation, the first of which may be compared with that of larva. An advancement, or progressive increase in the number of feet, is also well known to take place in species both of the julus and scolopendra genera, after they are produced from the egg state. The julus fabulosus, when first excluded, is furnished with three pair of legs, which are situated at each side near the head: some days after about fourteen become visible, and the remainder, to the amount of one hundred and twenty on each side, are gradually acquired afterwards. The same remark will apply to certain species, if not the whole of the scolopendræ genus. Scorpions are produced by the female parent in a living state; they are at first very small and white, and become of a darker hue in a few days: these, like the spiders, cast their skin as they increase in size.

### *Of the Pupa state.*

By this term, as understood in the very extensive sense Linnæus proposes, we comprehend that state of an insect which succeeds the larva and precedes the pupa, without any regard to the particular appearance it assumes in this stage of transformation. From this latitude of meaning it includes, therefore, with equal precision, and no less propriety, states of the most discordant character. It alike implies the uncouth grub incased in its shelly repository, and immured in the earth, sluggish, almost destitute of motion, or the appearance of any other animal function, with the lively half-winged locust, or the cicada, animals sporting in the full enjoyment of life. The bot, imprisoned in its oval covering, without the least external sign of animation, is termed a pupa. The moth, quiescent and abtinent for months, concealed in its shelly covering in the earth, or suspended aloft in its silky envelope to the branch of a tree, is a pupa; and we denominate those pupæ also which have the wings only half expanded; though, like the nimble-footed cimex, they are perpetually roving, and deriving sustenance from the blood of other animals; and so also the restless libellula, which is continually traversing the watery

element, with the facility of fishes in search of prey. Surely the difference between these is too great to be defined by any single term.

Writers have observed, that before the time of Linnæus this state of transformation was known only by the term chrysalis, a word derived from the Greek, and expressive of that golden lustre peculiar to certain butterflies; but this appearance not being general, the word was changed by Linnæus to that of pupa, in allusion to the indistinct resemblance which many insects in that state bear to a child swathed or dressed in swaddling clothes. These observations are certainly incorrect, for the word nymph, implying exactly the same fanciful comparison, was in use before the time of Linnæus; the earlier authors so named one particular tribe of insects in this state, namely, those having all their limbs inclosed within a skin: Linnæus adopted the idea but changed the word to pupa, and assigned it indiscriminately to all insects in that period of transformation from which the perfect fly is produced.

If we take a retrospective view of the state of entomology before the time of Linnæus, and consider attentively the terms by which the different states of insects were then known, there does not appear much reason to commend the alterations which he has introduced. From the labours of Swammerdam, Reaumur, Roefel, Lister, Ray, and others, the transformations of insects were then generally known, and particular terms had become established by which the several states, appearances, &c. might be discriminated. These were not sufficiently numerous, and of those in use some were less expressive than could be wished; but it is still not to be concealed that some, at least, were preferable to those introduced by Linnæus. This is the more to be regretted, as Linnæus wrote under favourable circumstances, and on his authority the introduction of a few expressive terms would have been attended with particular advantage. For instance, we should have conceived it desirable if he had designated this state of insects, which he calls pupa, by different terms, applying to each particular family a name at once expressive of their state, and the order to which they belong. When, in the works of his predecessors, we read either of the aurelia, nymph, or semi-nymph, we know that in a word it implies the same state as Linnæus means by pupa, with this additional information, that it is either of the dormant kind, like the moth, or active, like the nepæ, &c.; the Linnæan name conveys no such additional information; it applies without distinction to all, and merely intimates its state of transformation.

Perhaps the alteration of the word chrysalis to pupa may be thought by some an amendment; we do not disapprove of it, but object to the very indiscriminate sense in which it is employed. As it applies to the nymphs of one family described by earlier writers, it is admissible; to others it is not. Or if the term pupa were adopted in its most extensive sense, to comprehend this state throughout the whole race of insects subject to this period of transformation, the want of terms to distinguish the particular tribes of which they consisted would be equally felt. The general manner in which the term pupa is applied by Linnæus, and the inconsistency attending it, cannot be more fully exemplified than by the following circumstance. Linnæus, we are told, changed the word chrysalis to pupa, because the former implied a golden appearance not observable in all the species; yet he applies the word pupa, which he defines as alluding to the appearance of a child in swaddling clothes, such as we see in the moth and butterfly tribe, to the blatta, gryllus, cimex, and a host of other active creatures which exhibit no such resemblance, and which bear

## ENTOMOLOGY.

no relation whatever to the others either in manners or aspect! The first of these were called by old writers nymphs, the latter semi-nymphs; but these distinctive terms are confounded by Linnæus under the single term pupa. Surely the impropriety is as great in the alteration made as in the error it is designed to remedy.

To obviate, in some degree, the confusion arising from this general adoption of the word pupa, Linnæus proposed afterwards to divide them, according to their form, into five families, to each of which he assigns a trivial or secondary name.

These distinctions are not objectionable, but are rather too few in number, and they are certainly not expressed in terms suitable for general use. Nor does Linnæus himself appear satisfied with them, for although they are inserted with definitions at some length in the "Fundamenta Entomologia," they are not adopted in the "Systema Naturæ," and are for this reason rather to be regarded as matter of curiosity than of utility. The pupæ are divided into sections, according to the following circumstances. When confined in a case of a globular form, which has no resemblance to the insect it contains, it is called *coarctata*, or straightened, the examples of which are the musci and oestri; *obscûta*, disguised or shrouded, when the insect is wrapped up in a shelly covering of such a form that the part which contains the head and thorax may be distinguished from that wherein the abdomen is lodged, as in lepidopterous insects. It is termed *incompleta* when the pupa has perceptible wings and feet, but cannot move them: *semi-completa*, these can walk or run, but have only the rudiments of wings. The difference between the pupa and the larva of this class is very inconsiderable; in the first state they have no wings, and in the pupa the wings begin to be developed as in the grasshopper: *completa*, in which the egg may be considered analogous to the pupa, the insect being produced in its perfect form from the egg without passing through any other change.

Swammerdam divides insects into four classes, the characters of which are founded principally upon their appearance in this state of transformation, and the particulars attendant thereon.

The first of these comprehends those insects which, after being formed in their egg without the aid of food, and which, after having acquired, by the evaporation of the superabundant humidity, the necessary consistency, quit that state, and issue from the shell under the form they are to retain during life, without undergoing any other transformation, as instanced in the spider.

The second consists of those insects which, after leaving the egg, are without wings, but with all the other members, as in the perfect insect; in this state they eat and grow, pass into the nymph form, and from that issue with perfect wings, and with the ability to propagate their species. The dragon flies, grasshoppers, and cimices are of this family.

The third includes all kinds of butterflies and moths. They issue from the egg which lay in a disguised state and without food; the second state eats and grows, and the members of the animal into which it is to be transformed are formed under the skin, which it at last quits and becomes a nymph, and then after the evaporation of the superfluous humidity produces the perfect insect.

The fourth family, after having arrived at the nymph state, like those before-mentioned, does not divest itself of the skin in order to enter into that state, but assumes the form of a nymph under its skin, where it continues shut up, till quitting two skins, at once it comes forth in its perfect state. This is the metamorphosis which ichneumons undergo. These are the four families into which Swammerdam divides insects,

and the explanations he affords; and these, with some improvements and modifications, form the basis upon which the pupæ are arranged by many of the continental naturalists at this time.

The following observations on the same subject by Lyonet deserve attention. "By the term nymph (says this writer) is meant a state of imperfection, attended sometimes with inactivity, inaction, abstinence, and weakness, through which the insect passes, after having attained a certain bulk, and in which its body receives the preparatives necessary for its passing to a state of perfection, all the external parts of the insect are then found enveloped, either with their natural skin, or with a fine membrane, or with a hard and crustaceous crust. In the first case the limbs of the insect remain free, it preserves its power of acting, it eats, and its form is little different from what it was before. In the second case the limbs of the insect are folded over the breast but separate; it can neither eat nor act, it retains hardly any traces of its former figure, and has only a confused resemblance to that which it is going to assume. In the third case, the cover brings all these parts of the animal into one mass; it makes it equally incapable of eating and acting; it has no resemblance either to what it formerly was, nor what it is to be. These three sorts of change are evidently very different, and yet we have only two words in our language (French) to distinguish them by. We say of the insects in the two first cases, that they are changed into nymphs, and of those in the last case that they have assumed the form of chrysalids. To these terms it would be proper to add a third, in order to mark the difference between the two first. It might be done I think very conveniently by allowing the last to retain the name of nymph, and calling those of the first kind semi-nymph, or demi-nymph, a name which would not perhaps be inapplicable to them, considering the small degree of change they have undergone. Grasshoppers, which, instead of the long wings they acquire, have still only on their backs the small cases in which these wings are formed, are nymphs of this kind; they may properly be called semi-nymphs. Those who have had an opportunity of examining a bee hive, cannot fail to have remarked bees still imperfect in the shut cells; these are the nymphs of the second order. The silk-worm furnishes a well known example of insects under the form of chrysalis.

"Insects which undergo no other metamorphosis than that which has converted them from the soft substance of an egg to a well formed and living body, are those which constitute the first class of transformations spoken of. They increase in size, the greater part cast their skin; some of their parts acquire greater size than the rest, and sometimes take a different colour from what they had before. This is almost the only change they undergo. The transformations of the insects of the other three classes do not terminate here; after having cast off their skins for the most part several times, and after having acquired their destined bulk, all become either semi-nymphs, nymphs, or chrysalids. They pass a certain time under this form, and upon quitting it assume that of a perfect insect, capable of generation. It is from the diversity which takes place in these three sorts of changes that the principal characters, which distinguish the insects of the second from those of the third, are taken."

The insects of the second class are those that pass through the state which Lyonet calls semi-nymphs. They do not undergo a transformation which is entirely complete, but in their last change they have still generally all the members they had before, without having acquired any others, except

cept they have wings; and as already remarked the semi-nymph differs very little from the animal which produced it. What always distinguishes it is, that there are seen upon its back at the base of the thorax the cases in which the wings are formed, which before that appeared but little, and often not at all. In other respects it walks, runs, leaps, and swims as before. The difference between the semi-nymphs, and the winged insect which it produces, is not always so obscure. In some species it is so large that it is with difficulty we can discover its first form. But the greater part in their last state differ chiefly in the wings.

The insects of the other two classes do not enjoy the same advantages as the other. They lose the use of all their members when they enter upon their transformation, and have no resemblance to what they were before. An animal of these two classes which before had no legs, or had five, six, seven, eight, nine, or ten pairs, has now no more than three pairs, which, with the wings and antennæ, are folded up under the breast and remain immovable.

What distinguishes these two last classes from each other is, that the insects of the third class quit their skin, when they change into nymphs or into chrysalids, and that those of the fourth change into nymphs under their skin, which hardens round them, and forms a case.

Reaumur found, in the transformation of insects of the fourth class, a character that seems to distinguish it essentially from the rest, namely, that they changed into nymphs without quitting their skin. He discovered that they undergo one transformation more than other insects; because before they become nymphs, they assume under their skin an elliptical form, or that of an elongated spheroid, in which no part of the animal is discernible; that in this state the head, thorax, wings, and legs of the nymph are inclosed in the interior cavity of the abdomen, from which they issue successively by the anterior part, nearly in the same manner as the extremity of the finger of a glove, which has been drawn in, is pushed out again. Thus, the insects of this class are not solely distinguished from others by their changing into nymphs under their skin, but principally in undergoing a double transformation before they become nymphs.

Bergman distinguishes three kinds of pupa, which he calls chrysalids, nymphs, and semi-nymphs. The first he describes as hard and motionless, that does not eat, and shews obscurely the members of the future insect; the nymph is tender, lying at rest, not eating, and which shews clearly the separate members of the future insect; the semi-nymph is furnished with legs, and runs, eats, and is hardly different from the larva, except in having the rudiments of the wings, which the larva wants.

This inquiry, if duly pursued, would lead to much farther digression. From what is already advanced we presume it will be apparent, that the writers prior to the time of Linnæus, or cotemporary with him, (for those alone are mentioned,) are not agreed in their manner of distinguishing insects in this third state of transformation; and that their appearance is so various in different tribes, while in this state, that they ought to be distinguished by several, instead of a single name. Fabricius, one of the most considerable entomological writers since the time of Linnæus, employs the word pupa in the same general sense as the latter; but he is the principal late continental writer worthy of consideration, who has imitated this example. The French naturalists chiefly follow Lyonet, with some slight variation. This arrangement is still susceptible of much improvement, but is notwithstanding perhaps the most perspicuous yet proposed. To the chrysalis properly so called, namely,

Vol. XIII.

those of the butterfly tribe, this name given to them by the Greeks is retained; the rest of those which have their members enveloped in a common skin are called nymphs, and are divided into three or four families, according as those parts are more or less visible through the exterior membrane. The term *fève* (bean) is also introduced, to express in a general manner this state of the insect, when of an oblong form, and distinguished only by a few annulations and eminences. Insects in the third state, which differ only from the perfect form in having half-wings, are called semi-nymphs.

In the present section, to avoid confusion, it may be more convenient to adopt the Linnæan term, and under this head, describe such of the leading differences in insects as are observable in this state of transformation.

*Coleoptera*.—The nymphs or pupæ of this order have commonly the limbs detached or not laid under the exterior envelope close to the body, as in lepidopterous insects. Most of them bury themselves in the earth previously to this change; some form cells in decayed trees, others perforate seeds and nuts, and great numbers remain in the dung of animals, or other filthy substances, where the larvæ have been nourished. Their appearance, while in this state, is nearly the same in all, an emollient pupa of a whitish colour tinged more or less with brownish, and in form remotely resembling that of the moth kind, but with the limbs distinct. The mutations of *scarabæus nasicornis* affords an interesting description of the pupa of a coleopterous insect, and may serve as an example for the rest of the tribe. When the time approaches for this larva to change into the pupa form, it penetrates deeper into the ground than the larva had done before. Having found a proper place, it forms with the posterior feet a polished cavity, in which it remains for some time immovable; after this, by voiding excrementitious substances, and the evaporation of moisture, it diminishes in size, and the skin becomes furrowed and wrinkled, as if the animal were partly starved. If dissected at this time, the head, belly, and thorax may be distinguished. While some external and internal parts are changing by a slow accretion, others are gently distending by the force of its impelled humours. The body, contracting itself while the fluid is propelled towards the fore parts, forces the skull open in three parts, and the skin in the middle of the back is separated by means of an undulating motion of the incisions of the back; at the same time the eyes and the horns, &c. cast off the exuvia. During this operation, a thin watery humour is diffused between the old and new skin, which renders the separation easier. The process going on, the larva is at last disengaged from its skin, and the limbs and parts are by continual unfolding transformed into the pupa state: after which it twists, and compresses the exuvia at the vent, and throws it towards the hinder parts under the belly. The pupa is at this time very delicate, tender, and flexible, and affords a curious spectacle.

The pupa of this beetle weighs, a little time after its change, much heavier than it does in the beetle state, which is also the case with the bee and the hornet, which latter have been known to weigh ten times as much as the insect when perfect. If the skin be taken off at this time, many curious circumstances may be noted, but what claims our attention most, is, that the horn which is so hard in the male beetle when in a state of maturity, that it may be sharpened on a grind-stone, in the pupa is quite soft and like a fluid. How long this particular remains in this state is uncertain, some beetles of the same kind rest in this form the whole winter, more particularly those who quit the larva state in autumn. Some beetles go through all the stages of their

M n

existence

existence in a season, while others remain two or three years even in the pupa state.

When the proper time for their final change arrives, all the muscular parts grow strong, and are thus able to shake off their last integuments, which is performed exactly in the same manner as in the passage of the insect from the larva to the pupa state, so that in this last skin, which is extremely delicate, the traces of the pulmonary tubes that have been pulled off and turned out again become visible.

*Hemiptera*.—The pupæ in this order are the semi-nymphs of the old writers, and resemble the perfect insect in size and figure, but are without wings. The rudiments of these members, of larger or smaller dimensions in different species, are situated at the posterior parts of the thorax. They have the same manners, and subsist on the same food as the perfect insects; and we have reason for suspecting that some at least of these are not deficient in any of the animal functions.

*Lepidoptera*.—When the caterpillar of a butterfly or moth has attained its full growth, some writers affirm, that the rudiments of the perfect fly may be distinguished upon accurate investigation beneath the skin. This is asserted by Swammerdam, who declared he could demonstrate all the parts of the future butterfly in a caterpillar near the change. To discover this, it is directed, that the caterpillar be taken at the time the skin begins to open, when it is to be drowned in spirit of wine or some strong liquor, and to be left therein for several days, that it may take more consistency and harden itself, the skin of the caterpillar must be then removed, which will be easily accomplished, and the inclosed moth will appear. The rudiments of the future insect are extremely tender, and should be touched with the utmost delicacy, when the legs, antennæ, and other parts, may be unfolded and displayed to view. The parts of the moth or butterfly are not exactly disposed in the same manner in the body of the caterpillar, as when left naked in the chrysalis. The wings are said to be longer and narrower, being wound up in the form of a cord, and the antennæ are rolled up on the head, but in a very different manner from what it is in the perfect insect, and different from that in which it lies in the chrysalis; so that it is by a progressive and gradual change that the interior parts are prepared for the moth and pupa state; and even the eggs, hereafter to be deposited by the perfect animal, are to be found both in the caterpillar and pupa, the whole arranged in their natural and regular order.

Many of the chrysalides of the butterfly tribe possess a peculiar lustre in colour and brilliancy, resembling gold. It is not an appearance common to all butterflies, it is confined to certain species, and is not seen in any of the pupæ belonging to the moth tribe. This colour does not appear immediately in the chrysalides, but is assumed by degrees as the inclosed insect acquires consistency. It owes its splendour to the lustre of the white or light colour of the inclosed animal shining through the yellow transparent membrane of the case, as M. Reaumur has described in his work. This metallic appearance seems to have afforded a favourable pretext to the alchemists of former days, who were weak enough to draw delusive hopes from this appearance, and conceive it would afford them gold.

The following very curious and indeed instructive description of the chrysalis of a butterfly is given by our countryman Lister, nearly half a century before the science of entomology had made any considerable progress on the continent of Europe, and from which it would appear, that in his time the knowledge of that science was in a great measure confined to this country: it is from his annotations on the works of Goedartius.

“The middle state or disguise of a butterfly is called by the Greeks *chrysalis*, or a thing gilt, as the word importeth: the Latin hath left us no name that I know of; we have translated it *aurelia*. The Latins, however, call the caterpillar *eruca*; which is a word (as I guess from a place in Vitruvius), which signifies in the old Tuscan language *viride æris*, and thence borrowed to signify a caterpillar: for some caterpillars there are, which I have seen in Languedoc feeding on a certain common tithymal, very notably painted with a sea-green colour, or blue. So that as the gilding of some few chrysalides gave a denomination to all; in like manner, the blue colour of some one caterpillar gave the name to all the rest: as for the gilding itself, I take it to be nothing else but the scum of an evaporated juice between the skin of the caterpillar and the shell of the chrysalis, which last it covers.”

The butterfly remains only a short time in the chrysalis state, the interval between the larva and perfect state seldom exceeding ten, twenty, or thirty days. These chrysalides are commonly suspended by means of a few silken threads with the head downwards to the leaves or stems of trees, or against palings, &c. The chrysalis of the “common garden-white” is a familiar example of this mode of suspension, and of the brilliant appearance which this order of insects assume in this state.

The moth tribe remain much longer in the pupa form, and evince more care towards themselves, in making choice of a situation adapted to this defenceless stage of life. The caterpillar having acquired its full size, seeks for a proper place in which it may remain in safety during this period, and having made choice of this, prepares for the important change. Some spin webs or cones in which they inclose themselves, others conceal themselves in little cells which they form under ground, &c. Preparatory to the change the larva ceases to take any food, empties itself of all the excremental matter which the intestines contained, voiding at the same time the membrane which serves as a lining to these of the stomach. It generally perseveres in a state of rest and inactivity for several days about this time. In proportion as the change into the pupa form approaches, the body is observed to extend and contract itself very often: the hinder part is first disengaged from the skin; and after a while the skin is entirely cast off.

The caterpillar, thus stripped from its skin, is called the pupa; the exterior covering gradually becomes hard; while the interior remains so soft that the slightest touch will decompose them. The exterior covering is at first covered with a viscous fluid, which thickening and drying up, forms a thin skin or coat capable of resisting external injuries. Those who are desirous of tracing the various members of the future butterfly or moth in the pupa, should examine it before this fluid dries up.

The length of time an insect remains in the pupa form varies much in different species. As soon as the inclosed animal acquires sufficient strength to break the bonds of its confinement, it makes a powerful effort to escape. The moth frees itself from the pupa with greater facility than the pupa from the caterpillar; for the case of the pupa becomes so dry, when the moth is near the time of throwing off its covering, that it will crack and break to pieces if it be only gently pressed between the fingers; and very few of the parts will be found, on examination, to adhere to the body. Hence, when the insect has acquired a proper degree of solidity, it does not require any great exertion to split the membrane which covers it: a small degree of motion, or a little inflation of the body, is sufficient for this purpose; these motions reiterated a few times enlarge the hole,

hole, and afford the moth room to escape from its confinement. The opening through which they pass is always at the same part of the skin, a little above the trunk, between the wings and a small piece which covers the head: the different fissures are generally made in the same direction. If the outer case be opened, it is easy to discover the efforts the insect makes to emancipate itself from the shell. When the operation begins, there seems to be a violent agitation in the humours contained in the little animal; the fluids being driven with rapidity through all the vessels, the limbs and various parts of the body are put in motion, and by repeated efforts it breaks through the brittle skin that envelops it. Those inclosed in cones or cases, after bursting through the pupa covering, have another difficulty to overcome, that of piercing through the inclosure, which, in many instances, is of a stronger texture than the case of the pupa. For the accomplishment of this, most insects are provided with a liquor, which they discharge from the mouth upon that part of the cone through which they intend to escape, and this so moistens and weakens it, that after a short time they force their passage through with some facility. Some insects not provided with this fluid leave one end of their cone weaker than the rest, and close it only with a few threads, so that a slight effort of the head enables the insect to burst from its prison.

The butterfly or moth, on emerging from the pupa, is moist and humid, the abdomen swollen, the antennæ bent down, and the wings crumpled, small, and shapeless. These parts gradually change and assume their destined form. The wings extend, and the fibres, which were at first flexible, become hard and rigid like bone. In proportion as the fibres lose their flexibility, the fluids which circulate within them extend, and the wings cease to act; so that if any extraneous circumstance arrests the progress of this fluid through the fibres, at the first instant of the moth's escape, the wings immediately become crippled, and never afterwards assume any other form. These parts expand with such rapidity, that the naked eye cannot entirely trace their development. The wings, which at one instant are small and like four little buds at the sides of the thorax, in a few minutes after acquire their full size, so as to be nearly five times as large as they were before. Nor are they the wings only which are thus increased: all their spots and marks, heretofore so indistinct and small as to be scarcely discernible, are proportionally extended, so that what before appeared as only so many unmeaning and confused points, become distinct and beautiful ornaments. When the wings are unfolded, the tongue rolled up, the mouth sufficiently dried; and the different members strengthened, it takes its flight. Most insects, soon after they have attained their perfect state, void an excrementitious substance, which some suppose to be the last they eject during life.

If the moth be now opened down the belly, and the fatty parts which fill it be removed, the gross artery or heart will be visible, and the contractions and dilatations, by which it pushes forward the liquor it contains, may be easily observed. One of the most remarkable circumstances is, that the circulation of this fluid in the moth is directly contrary to that which took place in the caterpillar. In this it moved from the tail to the head, whereas in the moth its current is from the head to the tail. The intestines are now formed in a more delicate manner, and suited to a purer aliment than that on which it subsisted before its change into the pupa: the caterpillar devoured the grosser parts of vegetables; the nutriment of the perfect insect is the nectar of flowers. Many internal parts of the caterpillar disappear in the pupa, and many that could not be before perceived

are at length rendered visible. And thus the creature, which heretofore crept on the earth, flies freely through the air, and, far from creating aversion by its foul appearance, now attracts attention by the elegance of its form and beauty of colour.

The industry of the caterpillar in the construction of its cocoon, or other repository, in which it passes the time destined for it to remain in the pupa state, is highly worthy of remark. Some caterpillars, towards the time of their change, suspend themselves from the branch of a tree, with the head downward, and are transformed in this position. Many of the moth kind cover with threads that part of the branch from which it means to suspend itself: it places these in different directions, and then covers them with other threads successively, till the cone in which it is to become a pupa is finished. The caterpillar hooks itself by the hinder feet to this hillock; and when it has found by several trials that it is strongly fixed thereto, throws itself forward, letting the body fall with the head downwards. Soon after it is thus suspended it bends the fore part of the body, which posture it retains for some time; then stretching the body, again in a little time beading it, and so on, repeating this operation till it has formed a slit in the skin upon the back. Part of the pupa soon forces itself through this, and extends the slit as far as the last crustaceous feet: the pupa then forces upwards the skin, by means of its little hooks, and the motion of the body, till it has slipped it off to that part from which the caterpillar had suspended itself.

The mode of suspension adopted by some insects is very different from that pursued by others. Some fix themselves in an horizontal position, by means of a girdle, which they tie round the body, so as to support the caterpillar, and yet leave it at full liberty to effect the changes: others suspend themselves in webs, in temporary habitations, formed by weaving together two or three leaves of the plant on which they feed, by means of silken threads. The industry of those which spin cones or cases, in which they inclose themselves, in order to prepare for their transformation, is very generally known from the familiar history of the common silk-worm, an insect from which man derives the most essential benefits. In northern Europe these advantages are scarcely known, and are esteemed valuable only in proportion as they contribute to the luxury of dress; because our woollens are better suited to the vicissitudes of the climates. But in a far more extensive portion of the habitable globe, silk constitutes an article of the first necessity in useful clothing; and hence the labours of this industrious little creature become in the highest degree important and beneficial to the human race.

The silky tissues of this insect are spun by the caterpillar, for the sole purpose of enveloping and suspending itself in security during its pupa state. The substance of which the silk is formed is a fine yellow transparent gum, contained in two reservoirs that wind about the intestines, and which, when unfolded, are about ten inches long: they terminate in two exceeding small orifices near the mouth, through which the silk is drawn or spun to the degree of fineness which its occasions may require. This apparatus has been compared to the instrument in use for drawing gold and silver into threads. Each thread proceeds from the two reservoirs at the same time, but they are united as the thread forms; so that, if examined by the microscope, it will be found to consist of two cylinders or threads glued together, with a groove along the middle, and in which sometimes even a separation may be perceived.

When the silk-worm is near the time of change to the pupa,

## ENTOMOLOGY.

pupa, the reservoirs of silk are full, and it is pressed by its sensations to relieve itself from this incumbrance. Having made choice of a convenient situation, the operation of spinning commences. At first it throws out some loose thread, which serves to support the future superstructure: upon these it forms an oval of a loose texture, consisting of what is called flos silk; and within this it forms a firm and more consistent ball of silk. It is now inclosed within the circumference of the spheroid, the interior of which is the scene of its further operations: in this it is seen resting on its hinder parts, and with its mouth and fore legs directing and fastening the threads. These threads are not directed in a regular circular form, but are spun in different spots, in an infinite number of zig-zag lines; so that, when wound off, it proceeds in a very irregular manner. This thread, when measured, has been found to be about three hundred yards long, and so fine that eight or ten are generally rolled off into one by the manufacturer. The silk-worm usually employs about three days in finishing this cone; the inside is generally smeared with a kind of gum, which is designed to keep out the rain. It next assumes the pupa form, in which it remains from fifteen to thirty days, in different climates, before the moth is produced. When the insect intends breaking from the cocoon, it moistens one end of the cone, and by frequent motions of the head loosens the texture of the silk, so as to form a hole without breaking it. See *SILK-WORM, Phalana Mori*.

From a series of experiments made by Reaumur on the silk of this insect and that of the spider, in order to ascertain their comparative excellence, it was found that the thread would bear the weight of thirty-six grains, while that of the spider could not sustain twelve grains, breaking under its weight. There are silks spun by other insects, with which we are little acquainted, that in point of strength far exceeds that of the common silk-worm. The popular opinion, that the silk worn in different parts of the world is the sole produce of this species (*phal. mori*), is erroneous. This kind of silk is generally esteemed for its peculiar beauty and delicacy of texture. There are others less costly, which, from their superior strength, are better adapted to common wear, and are for this reason in more general use in some parts of the globe. The silk obtained from the cocoons of the two species of *bombyces paphia* and *cynthia* are of this kind, as appears from an interesting paper on these insects by Dr. Roxborough, F.L.S., inserted in the seventh volume of the Transactions of the Linnæan Society.

These insects bear the names of tuffeh and arrindy silk-worms in India: both exceed the common silk-worm in size, the first especially, which is one of the largest of the attaci family of bombyies, and the silk of which appears to be more valuable than that of the other kind.

The tuffeh silk-worm is found in such abundance over many parts of Bengal, and the adjoining provinces, as to have afforded the natives from time immemorial an ample supply of a most durable coarse silk, commonly called tuffeh silk, which is woven into a kind of cloth called tuffeh doot'ries, much worn by the Bramins, and other sects of Hindoos. This substance would no doubt be highly useful to the inhabitants of many parts of America, and the south of Europe, where a cheap, light, cool, and durable dress, such as this silk makes, is much wanted. The caterpillar, when full grown, is about four inches in length, and bulky in proportion; its colour green, with a lateral stripe of yellow edged with red. The plate in which the caterpillar is represented, if we mistake not, is engraven from a drawing executed by an Indian artist, and must be received with

some allowance for inaccuracy; but from this we may collect that it has a single series of yellow oval dots beneath the lateral line, (amounting to six or seven in number,) which are perhaps its spiracles; and these, in the description, are denominated specks of gold colour. When these are ready to spin, each connects, by means of the recent glutinous filament of which the case is made, two or three leaves of the jujube tree, the vegetable on which they feed. These connected leaves form an exterior envelope, which serves as a basis to spin the complete case or cocoon in; and "besides this," says the writer, "the case is suspended from a strong branch of the tree in a wonderful manner by a thick, strong, consolidated cord, spun of the same materials from the bowels of the animal." It remains nine months in the pupa state. The insect, when produced, expands to the breadth of five or six inches, and those of the female to eight inches.

There is another kind of wild silk-worm produced in the Burbhoom hills, which is said to be more capable of being domesticated; and a fourth sort, a supposed variety of the tuffeh-worm, in the hills near Bauglipore, the cocoon of which is smaller than that of either of the two first mentioned.

The arrindy silk-worm still remains to be noticed. This is of a species altogether different from the former, and is the *bombyx cynthia* of entomologists. This insect, known to the Hindoos by the name of arrindy in some parts, and in others arrundi, appears to be peculiar to the interior parts of Bengal; and it is presumed, may be even confined to the two districts Dinagepore and Rungpore, where the natives breed and rear it in a domestic state, as they do the common silk-worm. The food of the caterpillar consists entirely of the leaves of the common ricinus or palma chrilli, which plant is cultivated abundantly over every part of India, on account of the oil obtained from the seed. The Hindoos call this plant arrindy, and hence is derived the name of the insect. The caterpillar, when full fed, is about three inches long; the colour pale green; and each segment verticillated with a few conic tubercles disposed in a single line. The cocoon is white or yellowish, of a very soft and delicate texture, about two inches long, and three in circumference, and pointed at each end. There is a wide distinction between this species and *B. paphia*, in the period it remains in the pupa form; this requiring at the utmost not above twenty days, instead of nine months, to complete its last transformation.

The filaments of which the cocoon is composed are so exceedingly delicate, that it is said to be impracticable to wind off the silk: it is therefore spun like cotton. The cotton, thus manufactured, is wove into a coarse kind of white cloth, of a seemingly loose texture, but of incredible durability; the life of one person being seldom sufficient to wear out a garment made of it, so that the piece descends from mother to daughter. Some of the Indians, however, have a method of spinning the silk of this species, and the process is related as follows. Four or five of the cocoons are fastened to a piece of wood, with something heavy to make it spin round, while suspended by the thread. When they let out a sufficient quantity of the cocoons from their hand, it is twisted by this piece of wood spinning round; and when well twisted, it is wound round the wood, and another length let out of the hand. The cocoons are spun wet, but only with cold water. The cloth is woven in small pieces in a loom: its uses are for clothing for both men and women; it will constantly wear ten, fifteen, or twenty years. This silk must be always washed in cold water; for if put into boiling water, it will tear like old rotten cloth. Some manufacturers

## ENTOMOLOGY.

manufacturers seem to be of opinion that shawls, and other silken articles of dress, equal in quality to any manufactured in India, could be fabricated with this material. There is reason to apprehend that this silk is highly valued in India; nor can we entertain the least distrust of its want of durability, since it is well known that the coverings of their palanquins are of this particular kind of silk.

On further investigation and research into the history of the larger species of the bombyx tribe, we are persuaded others will be found to form cocoons or pupa spinings, which, with proper attention and culture, may hereafter be productive of similar advantages. We are not ignorant that in other parts of Asia, and in America, there are many species that spin in the same manner an envelope round the pupa; and some of these at least, we must suppose, capable of producing a silk of beauty and durability equal to some of those in present use. We should not be surprised to learn that bombyx atlas, the most considerable in magnitude of all the moth tribe, is expressly reared in China for the sake of its silk. We suspect this to be the truth. It would be desirable also to ascertain whether the cocoons of the species hesperus, cecropia, cytherea, promothea, and some others, could not be beneficially employed in the production of silk. Mr. Abbot, in his *Insects of North America*, speaks generally of some attempts being made to fabricate the silk of one or two of the larger moths of that country; the cloth prepared from which is represented as strong and durable; but he expresses doubt how far the experiment might be useful, as the insects which produce the silk are not abundant. This objection might easily, we should imagine, be obviated by cultivation: insects are highly prolific, and if they could be reared in what may be termed a domesticated state, could be produced in any numbers.

Among a variety of other curious information which this paper conveys, the following circumstances appear so amusing, and seem to reflect such new light on the history of these useful insects, that we cannot refrain repeating them. The cocoons of this insect, bombyx paphia, feed on the leaves of a plant called byer by the Hindoos (*rhamnus jujuba*), and likewise on the plant they call asseen (*terminalia alta glabra* of Roxb.). They are annual, remaining nine months in the pupa state, and three months in that of the egg and caterpillar. The species cannot be domesticated, nor can the natives even retain any for feed. The hill people say, they go into jungles, and under the byer and asseen trees they find the excrement of the insect; on which they examine the tree, and, on discovering the small worms, they cut off branches of the tree sufficient for their purpose, with the young brood on the branches. These they carry to convenient situations near their houses, and distribute the branches on the asseen tree, in proportion to the size of them; but they put none on the byer tree. The Parieahs, or hill people, guard the insects night and day, while in the worm state, to preserve them from the crows and other birds by day, and from bats by night. As soon as the moth pierces the cases, it escapes; nor do the people prevent this, as they have learnt by experience that it cannot be kept alive more than a few days, and that retaining it would not be attended with any advantage.

To wind off these cocoons, the natives put them into a ley made of plantain ashes and water for about two hours; after which they take them out of the ley, and put them in their wet state into an earthen pot: those which are properly softened are first applied to the reel, and so on as the cocoons become soft, for four or five days, till the whole

are wound off. The implement used for taking off the thread is a small common reel of four bars. The cocoons are laid in a smooth earthen dish without water; the reel is turned by the right hand, whilst the thread of four or five cocoons passes over the left thigh of the spinner, and he gives the thread a twist with his left hand upon his thigh. The thread is exceedingly apt to come off double and treble for several yards together, which is not regarded by the natives, as breaking off double threads would diminish the produce, and moreover would occasion loss of time: a very even thread, however, with care may be reeled off. The bughy silk-worm feeds indifferently on byer or asseen leaves.

The jarroo cocoon is the pupa spinning of an insect closely allied to the preceding, but whether a distinct species or variety, from the knowledge we at present possess, seems difficult to determine. These are called the jarroo cocoon, from being produced in January, the coldest month of the year; and the natives affirm, that they are different from the bughy. The jarroo will eat the byer leaf, if it cannot get the asseen; but will always prefer the latter, and will produce better cocoons when fed on it. The silk is duller in colour. The natives are able to retain part of the jarroo cocoons for feed. These they hang out on the asseen trees, when the proper season of the moth arrives. The males, when hatched, invariably fly away; but the females remain on the trees. These are not impregnated by the males bred along with them, but in ten or twelve hours, or perhaps two or three days, a flight of males arrive, settle on the branches, and impregnate the females; and it is worthy of remark, that the hill people consider it good or ill fortune, in proportion to the speedy or tardy arrival of these male visitors. The purposes of nature accomplished, the males expire, and the females live only long enough to deposit the eggs in safety on the branches of the trees. These males are supposed by the natives to come from a vast distance: it is affirmed even, that by marking the wings of a number of males, previously to letting them fly, their progress in quest of the females has been traced to the distance of one hundred miles and upwards. This, though remarkable, is not more extraordinary or unworthy of credit than the circumstance (if truly stated), that the males and females of the same brood never associate together in any manner, when they enter the fly state; the males regularly flying off in search of another brood of females, and leaving those of their own family to the embraces of another flight of males.

There is a caterpillar which forms its silken cone in the shape of a boat turned bottom upwards, whence it is called by Reaumur "coque en bateau." It consists of two principal parts, each of which is framed by itself, and formed of an innumerable quantity of minute silk rings; in the fore part there is a projection, in which a small crevice may be perceived, which serves when opened for the escape of the moth; the sides are framed with so much art, that they open and shut as if framed with springs; so that the cone from which the fly has escaped appears as close as that which is still inhabited.

Those caterpillars which do not spin a cone supply that want with various materials, which they form into a habitation to secure them from injury while in the pupa state: some form a covering with leaves and branches tied or made fast together, others connect the leaves with great regularity; many strip themselves of their hairs and form a mixture of hair and silk, others construct a cone of sand or earth, cementing the particles together with a kind of glue:

some gnaw the wood into powder, or like saw-dust, and cement it together; and others make cases in holes, which they form in the trunks of trees.

The period of their change into the chrysalis or pupa state is very regular in most insects, unless in seasons peculiarly unfavourable. Some change in May, others in June, July, August, and September, and the time of emerging from the state of pupa is fixed with no less precision. This is a fact well known to every practical entomologist. Some remain in the pupa state only twelve or fifteen days, others twenty or thirty, and these are chiefly of the butterfly tribe. Those of the moth kind are commonly much longer, some remaining in this state only two or three months, others six, nine, or twelve, some two years, and others even it is known so long as three years. Lyonet has remarked, that the periods of change to the chrysalis state is not so constant, but that a degree more or less will affect it. The same insect, he says, which in the middle of summer would have acquired its utmost size in less than three weeks, will require as many months, and even much more if it comes forth at the end of the season. And again, he observes, that such a nymph or chrysalis which in summer will change into a winged insect in fifteen days, will employ sometimes six, seven, or eight months for the same purpose, merely from having gone into the chrysalis state a few days later than those which have changed so rapidly. That particular incidents may occasionally justify these remarks of Lyonet, we shall not dispute, but this can be only understood of insects hatched in seasons of unusual inclemency, or under circumstances in the highest possible degree uncongenial to their transformations. Irregularities will arise from this cause. In general, however, the appearance of every species (whose history is once correctly ascertained) whether in the larva, pupa, or winged state, may be determined by the time of the year. Most insects perform all their changes within the course of twelve months, and are found in their several states at particular periods annually; others have two broods in the course of that time, and consequently appear in the same state at two different periods of the year.

*Neuroptera*.—Some of this order are semi-nymphs, as the libellulæ and ephemeræ, in which the rudiments or half-wings are developed, and which eat and pursue the same manners of life as the larva. Others are like the nymphs of the coleopterous order in appearance, and lie dormant in the ground, generally in cases constructed of extraneous materials. The myrmelion forms a hollow ball of sand for this purpose.

*Hymenoptera*.—In the pupa of the cynips the limbs are partially disclosed in its external figure, and it remains in the central cavity of the gall in which it lives during the state of larva, while in the pupa form. The tentredo forms a kind of exterior case or envelopement, within which it assumes the pupa form, and which in some kinds resembles the texture of thin parchment. The pupa of the firex is quiescent, and is usually found lodged in timber: this has the limbs distinctly formed. The pupæ of the ichneumons are inclosed in oblong silken cones. Those of the wasps and bees are well known. In the ants the limbs are distinct.

*Diptera*.—The pupæ of the tipulæ are usually cylindrical like the larva, and quiescent; many of the muscæ appear of an elongated egg shape, without any segmental divisions, and totally devoid of motion. The pupa of the culex is curiously incurvated and ovate, with respiratory tubes, through which it breathes; it is an inhabitant of the waters. The egg of the hippoboscæ serves in lieu of a pupa, or in other terms the hippoboscæ are oviparous, and have no pupa.

*Aptera*.—As the individuals of this order are produced with few exceptions in the perfect form from the egg, they have no pupa, at least the common flea is the only instance to the contrary; this undergoes the usual transformations from the egg to the perfect state; its pupa resembles that of some coleopterous insects when magnified.

*Imago*: the final or perfect state which all insects assume after passing through the successive changes from the egg, the larva, and pupa form; which latter it quits in the imago state. This might, with more simplicity, be termed the winged state, were it not that some insects, after quitting the pupa, are apterous, or without wings. In the imago form the insect is in every respect perfect in all its parts, and possessed of every function which nature has intended the species to enjoy.

#### *Habitation of Insects.*

Insects are of two kinds, aquatic and terrestrial, and their habitation must be considered separately.

Some live only in watery places, appearing occasionally on the surface of that element, and which very rarely plunge themselves in, or if they fall in, either rise again immediately to the surface or perish. Others live only in water, and cannot subsist out of it. Many, after having lived in the water while in the larva and pupa state, come out afterwards with wings, and become entirely terrestrial. Some undergo all their transformations in the water, and then become amphibious. Others again are born and grow in the water, but remain during the pupa state on dry land, and after they attain their perfect form live equally in air and water. There are, lastly, some who live at the same time occasionally both in the water and on land, and which, after their transformation, cease to be aquatic.

Among the insects which remain on the superficies of the water, are some spiders which run with great address and agility, without moistening their feet or their body. There are aquatic cimices which swim or rather run on the water with great velocity, and by troops, as may be often seen on the surface of still water. Some walk slowly on the surface. The gyrinus moves swiftly and in circles. The nepæ are of that kind which live only in the water, and cannot subsist out of it, or at least can remain out of it only a short time. The number of those which, after having lived in the water, leave it when in a winged state is very great: among these are the libellula, the ephemera, the phryganea, culex, tipula, and some other species of muscæ; all these are of the aquatic kind, both in the larva and pupa state, but when they have assumed their perfect form are entirely terrestrial, and would be drowned therein. The kinds most strictly amphibious are the water beetles, such as the dytiscus and hydrophilus; these remain in the water all day, but towards evening come upon the ground and fly about, plunging themselves again into the water at the approach of sun-rise: the larvæ of these insects are entirely aquatic; but when the time of their pupa state arrives they descend into the earth, where they make a spherical case, thus becoming entirely terrestrial, and in the perfect state are amphibious.
